REAPPRAISAL OF SURGICAL TREATMENT OF MAMMARY CARCINOMA

James J. Berens, M.D., Phoenix, Ariz.

The inevitable handling of soft tissues during mastectomy for mammary carcinoma increases the danger that tumor cells may be carried to nearby lymph nodes. Metastases laterally toward the axillary lymph nodes are visible and accessible and have received much attention. Metastases medially toward the supraclavicular and internal mammary nodes have not received sufficient attention, although they constitute the greater danger. The danger can be reduced by the type of operation here described. In it, the first incision is planned to block lymphatic and venous draining in the medial direction before beginning the extensive manipulations involved in mobilizing the primary breast tumor and dissecting the axillary structures.

IT IS the purpose of this study to reappraise the traditional procedure of radical mastectomy and to indicate the advantages of interruption of the pathways of lymphatic spread to the medial chain of lymph glands, in the initial stages of the operation, with a minimal amount of operative manipulation. The preferred therapy for breast carcinoma since 1894 has consisted chiefly of radical mastectomy performed according to the technique developed by Halsted[1] and Meyer.[2] Well-performed radical mastectomy can effect a cure of mammary carcinoma if no viable tumor remains in the patient at the completion of the operation. In view of the extensive dissection and handling of soft tissues in the performance of mastectomy, one should always be concerned with the threat of embolization of tumor cells produced by the manipulations in the course of the operation. Although lymphatic spread to the axillary glands is the most common route, the tumor is usually resectable in the axillary glands.

It is, however, the lymphatic spread to the supraclavicular and internal mammary chain of lymph nodes on the medial side of the breast that renders the carcinoma incapable of cure. One can only conjecture how frequently the embolic spread of carcinoma cells to these medial lymph glands occurs during the manipulations and dissections of radical mastectomy. Yet in spite of this knowledge the traditional radical mastectomy consists of a dissection proceeding from a lateral to a medial direction, with all the concomitant massage and manipulation which tend to encourage the lymphatic embolization of tumor cells to the medial chain of lymph nodes out of the range of resection by the commonly performed radical mastectomy. It is only in the final stages of this extensive dissection that the lymphatic routes to these medial lymph nodes are finally interrupted. No intermediate lymph glands exist on the medial side of the breast

within the resected portion of tissue to act as filter traps for the free-floating tumor cells in the lymphatics during the course of the resection.

The presence of clusters of carcinoma cells in lymphatic vessels and also in the peripheral sinuses of lymph glands in the surgical and autopsy specimens of mammary carcinoma evidence the active lymphatic embolic spread. It seems a simple corollary that the more extensive the manipulation and massage of cancerous tissues the greater will be the opportunity for embolic metastases. The importance of gentleness in handling malignant tissues has been stressed by Halsted, Meyer, and many investigators since their time. In 1913 Tyzzer[3] demonstrated that gentle massage of a transplanted carcinoma in a mouse greatly increased the number of metastases observed in the lung. Further experimental evidence was provided by Knox,[4] who demonstrated that gentle massage of breast tumors in the mouse increased the number of tumor emboli, which can produce metastatic tumors. The recent work of Roberts and co-workers[5] shows that there is an increase in the number of cancer cells in the circulating blood during the manipulations of resection of the tumor in human patients.

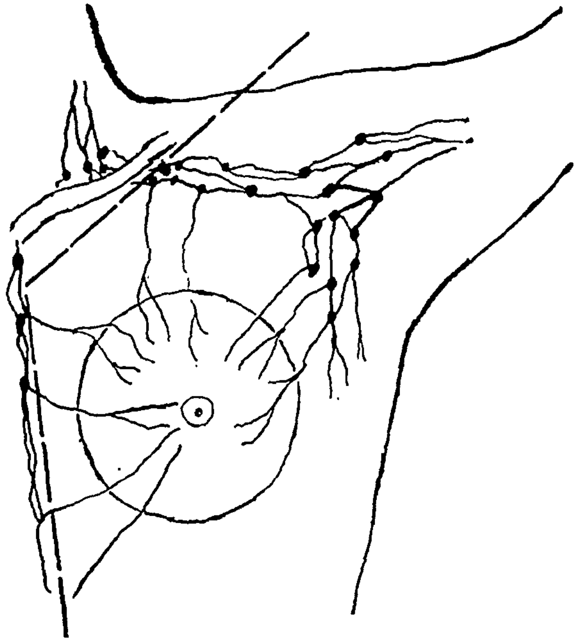

Fig. 1.—Diagrammatic illustration of lymphatic system involved in mammary carcinoma. *Broken line indicates sites of surgical interruption of the lymphatic channels as they course medially from breast and axilla.*

As a practical therapeutic approach one could, as a matter of thought, consider the primary carcinoma in the breast and the axillary gland metastases to be a functioning malignant unit, since routine surgical pathological studies indicate that the axillary glands are involved in one-half to two-thirds of cases. Both of these areas tend to spread through the lymphatic channels in a medial direction to the supraclavicular and internal mammary lymph glands.

Lateral Dissection Versus Medial Dissection as First Procedure

In radical mastectomy the lateral mobilization, consisting of the elevation of the lateral skin flap, the axillary dissection, and the mobilization of the breast from the lateral chest wall, is accompanied by much more manipulation and massage of cancer-bearing tissues than is the medial dissection, which consists of elevation of the medial skin flap, dissection of the breast and pectoral muscle origins from the thoracic wall, and division of lymphatics coursing medially beneath the clavicle. If the lateral dissection, as described above, is performed before the medial dissection in radical mastectomy, the lymphatic drainage to the medial chain of lymph glands in the supraclavicular and internal mammary chain is left intact during the extensive manipulation and massage of the dissection. The extensive lateral dissection tends to create a situation which encourages, by mechanical manipulation, the embolization ahead of the dissection through lymphatic channels which have not yet been interrupted and which do not contain lymph glands to act as filter traps.

Why is the lateral mobilization performed first? There are several significant reasons: 1. It is traditional as described by the original techniques of Halsted and Meyer and by the breast surgeons who have had extensive experience since that time. 2. The more technical portion of the dissection, mobilization of the breast from the lateral chest wall and the delicate axillary dissection, is completed in the early stages of the operation. It is a natural human tendency to do the more technical procedures early. 3. It is easier to maintain hemostasis of the perforating arteries and veins as they come through the chest wall from the internal mammary vessels after complete mobilization of the breast and pectoral muscle than prior to the mobilization.

Why should the surgical dissection and mobilization of the medial side be performed first? 1. First and foremost this approach interrupts the lymphatic channels from the primary tumor in the breast and the axillary lymphatic metastases, if they are present, to the supraclavicular and internal mammary nodes and to the lymphatics of the round ligament before the hydraulic massage of the extensive axillary and lateral breast mobilization. The lymphatic drainage of the breast is diagrammatically illustrated in figure 1, with the interrupted line representing the surgical intersection of the medial lymph channels. 2. A breast of moderate or large size is naturally inclined over the lateral aspect of the chest when the patient is in the supine position. This makes the elevation af the medial skin flap and the medial mobilization of the dissection more anatomic and necessitates less massage than does lateral mobilization and dissection. It utilizes the force of gravity, inclining the breast toward the lateral side of the chest for retraction, and it requires less manipulation to produce retraction. 3. There exist no intermediate lymph glands to act as filter traps between the medial chain of glands, consisting of the supraclavicular and internal mammary chain on one hand and the mammary gland and axilla on the other. 4. As a basic principle of cancer surgery it is advisable to attempt to interrupt the most distant route of spread that is feasible before the mobilization of the involved cancerous tissue. By analogy, in cancer of the rectum and rectosigmoid colon the highest point of lymphatic spread along the inferior mesenteric circulation is interrupted prior to mobilization and manipulation of the primary growth. Similarly, if one considers the primary breast tumor and axillary glands as a functioning malignant unit, since they are so commonly involved together, then one should logically first interrupt the most distally acceptable route of spread in the initial stages of the dissection before mobilizing the tissues involved by the malignancy. 5. The medial dissection simultaneously interrupts many of the venous routes of tumor spread as well as the lymphatic channels.

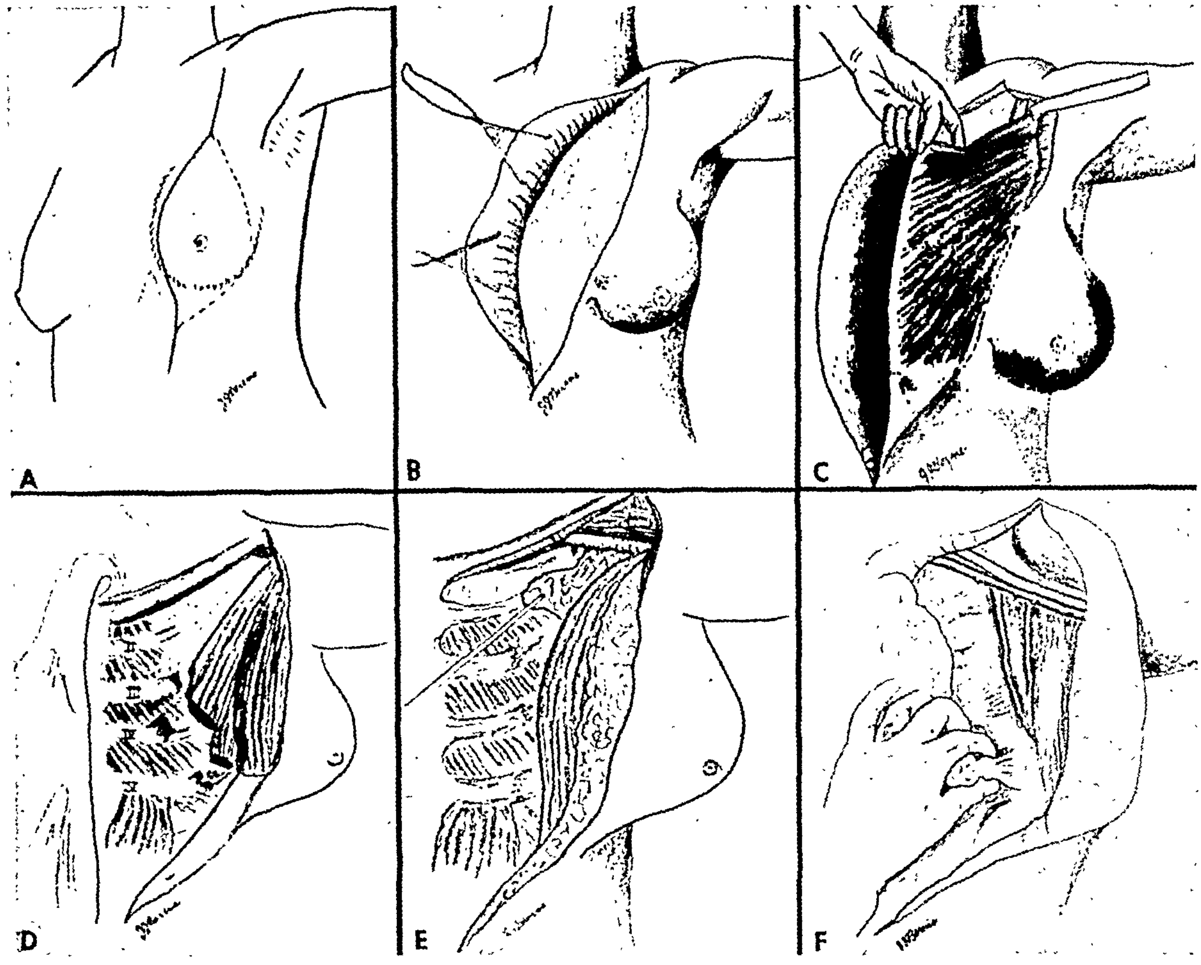

Fig. 2.—*A*, outlines of skin incisions for radical mastectomy. Medial skin incision is made along continuous line. Dotted line is for lateral skin incision, not made until all medial routes of spread are interrupted. *B*, medial skin flap is elevated with help of special skin flap hooks. Note that gravity force retracts breast laterally during dissection to reduce need for manual traction on tumor in breast. *C*, elevation of pectoralis major muscle, allowing division at its origin. *D*, elevation of pectoralis minor muscle, allowing division at its origin. *E*, deep axillary fascia is opened in subclavicular area to remove subclavicular lymph nodes and divide lymphatic channels before they course medially beneath clavicle to supraclavicular lymph glands and systemic venous system. Exposed tissues are then covered with moist compresses before lateral skin incision is made. *F*, radical mastectomy is completed by severing remaining structures from chest wall.

Preferred Operative Technique for Radical Mastectomy

Surgical management starts at the time of the physical examination of the breast for malignancy. Gentleness in the course of the physical examination of the breast tumor and axillary nodes is of obvious importance in reducing the amount of mechanical massage and manipulation to the suspected carcinoma. It is also worthwhile to advise the patient not to examine her breast any further between the time of the examination and the time she enters the hospital for definitive treatment. Many patients are prone to continue repeated self-examinations, since their attention is so strongly focused on the breast pathology.

In the operating room the surgical preparation of the field of operation should be either performed or supervised by the operating surgeon. Frequently the breast and the axillary area are prepared with such vigor in the mechanical cleansing of the skin that the massage is conducive to embolization of tumor cells. The cleansing and skin preparation should be adequate but gentle.

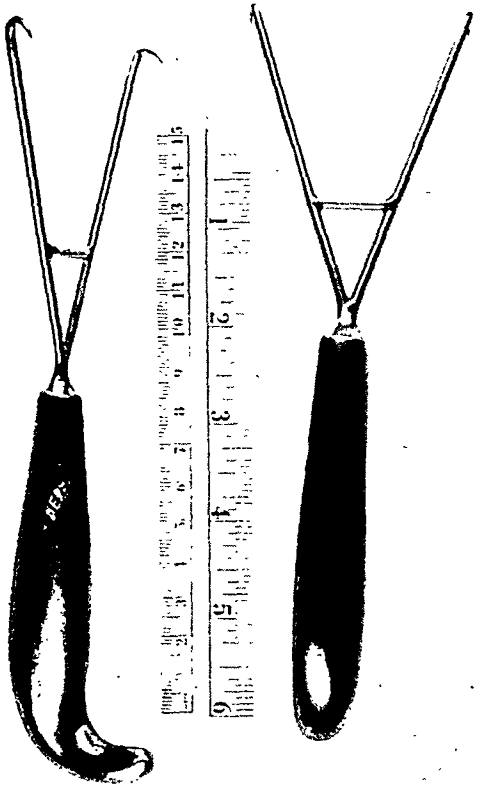

Fig. 3.—Mastectomy skin flap retractor.

Lines are then marked on the skin for vertical incision with the back of the point of the knife blade (fig. 2*A*). I use the vertical type of incision, encircling most of the mammary gland, going widely around the area of the tumor, and extending in a cephalad direction over the clavicle along the strap line.

The medial skin incision (fig. 2*B*) is then made with the operating table tilted laterally toward the side of the affected breast to aid in retraction by the force of gravity acting on the breast to displace it in a lateral direction. An adequately thin skin flap is prepared, extending the dissection to the midline over the sternum and to the clavicle.

Starting at the cephalad portion of the field the pectoralis major muscle is divided near its origin from the clavicle (fig. 2*C*). With the finger as the retractor the pectoralis major is elevated from the thoracic wall and dissected at its origin from the sternum and ribs. The perforating vessels from the internal mammary circulation are isolated, clamped, and divided as they are approached. The dissection is carried in a caudad direction and includes a portion of the anterior rectus sheath. The origin of the pectoralis minor muscle is similarly dissected from the chest wall (fig. 2*D*).

The deep pectoral fascia is then entered in the subclavicular area. Dissection is continued along the axillary vein to the point where it emerges beneath the subclavius muscle (fig. 2*E*). The subclavicular nodes, which usually number two to five in this area, are dissected out in continuity with the specimen. It is advisable to leave a long silk suture as an identification mark for the pathologist in the area of the subclavicular glands. The pectoralis minor muscle insertion is mobilized with finger dissection, clamped, divided, and ligated. Further dissection is carried medially from this area, isolating, clamping, and dividing the branches of the thoracoacromial vessels.

At this stage of the dissection the accessible medial lymphatic and venous routes of spread have been interrupted before the lateral skin or deep mobilization of the dissection has been started. It is this latter form of dissection which is accompanied by stronger traction and manipulation of the breast and axilla, which is conducive to embolization of tumor cells. The exposed area is then packed with moist compresses to protect the tissues from drying and to attempt to collect any carcinoma cells which pass through the severed ends of the lymphatic and venous channels during the remainder of the dissection. Whenever these gauze packs are disturbed, it is advisable to replace them with fresh ones rather than rearrange them.

The operating table is then tilted laterally toward the side of the uninvolved breast to allow the involved breast to be disposed in a medial position and thus permit the force of gravity to aid in medial retraction. The skin incision for the lateral flap is then made and the lateral skin flap is elevated. As the anterior border of the latissimus dorsi muscle is approached the thickness of the skin flap is increased. The dissection is continued laterally beyond the border of the latissimus dorsi muscle as an aid in mobilization of skin to facilitate closure of the skin flaps at the completion of the operation. Moist compresses are placed against the exposed tissues.

The pectoralis major muscle is then severed at its tendinous insertion into the humerus. Usually no bleeding follows the division of the insertion of the major muscle, if this is done at its tendinous portion. A small bundle of clavicular fibers of the pectoralis major frequently are left intact. The axillary vein is isolated by sharp dissection, and all branches are clamped and divided, since they course into the area of the resected specimen. The medial border of the latissimus dorsi muscle is mobilized and the axilla is entered from the inferior aspect. By sharp dissection all lymphatic and fatty tissues are excised in continuity with the breast. The thoracodorsal and long thoracic nerves as well as the subscapular vessels are preserved, if they are not involved in the neoplasm. The resection is completed by dissecting the remaining tissues from the thoracic wall (fig. 2*F*). The operative wound is thoroughly irrigated with saline solution, strict hemostasis is secured, rubber drains or suction catheters are inserted, and the skin flaps are reconstructed.

The dissection of large skin flaps, as in simple radical mastectomy procedures, is greatly facilitated by use of a retractor (fig. 3) which fulfills several requisites. These include (1) elevation of the skin flaps over a broad surface area to allow good exposure for the dissection, (2) minimal trauma to the tissues, (3) secure contact between the retractor and the skin flaps, and (4) adequate vertical tension of the skin to facilitate sharp dissection of thin skin flaps. The retractor shown in figure 3 contains two sharp hooks located 2½ in. apart. The use of two retractors placed several inches apart on the same skin flap greatly facilitates the dissection of the cutaneous flaps during mastectomy.

Summary and Conclusions

There is need for a modification of the surgical treatment of mammary carcinoma from the standpoint of interrupting the routes of embolic tumor spread in the initial stages of the treatment. I feel strongly that in some instances viable tumor cells spread beyond the confines of the resected tissues during the course of the traditional radical mastectomy as a result of the massage and manipulations engendered by the lateral and axillary dissections, and I have outlined an operative procedure which interrupts the accessible routes of medial embolization in the early stages of the operation, before any manipulation of the primary breast tumor or the main axillary dissection is performed.

PREOPERATIVE PSYCHIATRIC CONSULTATION

Edward M. Litin, M.D., Rochester, Minn.

Preoperative psychiatric consultation can help not only in cases in which operation may be contraindicated from the psychiatric viewpoint but also in cases in which operation will prove to be helpful. By critically reviewing the diagnosis of psychoneurosis, the psychiatrist has been responsible for operations that have proved lifesaving. Also, through careful evaluation, the psychiatrist can determine when an indicated surgical procedure is not likely to result in relapse into an earlier psychiatric condition. Five case reports illustrate these various possibilities.

With the growing acceptance and application of psychiatric principles, there has been an increasing demand for psychiatric consultations with medical and surgical patients. In the past, psychiatric consultations with surgical patients almost invariably followed operation. Cases were included in which the patient had become dependent on narcotics or in which surgical exploration had failed to reveal any pathological condition and the surgeon had concluded that the symptoms were psychogenic. Another equally troublesome and puzzling group of cases was that in which surgical removal of the pathological condition failed to remove the symptoms and, in fact, sometimes made the patient worse.

From the Section of Psychiatry, Mayo Clinic and Mayo Foundation. The Mayo Foundation is a part of the Graduate School of the University of Minnesota.

Read before the Southern Divisional Meeting of the American Psychiatric Association, Miami, Fla., Dec. 3, 1958.

Many surgeons in recent years have become more wary regarding elective operations and frequently request psychiatric consultation preoperatively. In the case of emergency operations, or nonelective operations such as operations for cancer, the psychiatrist's decision is easy. He indicates that, although postoperative psychiatric complications may well occur, there is no alternative but to operate and to handle the complications later. Even in these cases, however, it is desirable for the psychiatrist to have some knowledge of, and relationship with, the patient before operation.

Psychiatric Contraindications to Surgical Intervention

Many surgeons have intuitively recognized a poor surgical risk from the psychiatric viewpoint or have learned from sad experience the type of patient who should not be offered elective operation. These patients, however, are more easily recognized by the psychiatrist, and he has a better understanding of the basic dynamics involved. Thus, the psychiatrist can help the surgeon to formulate a program of treatment that is more conservative than a surgical approach. In fact, in many of these cases the preoperative psychiatric consultation results in psychotherapy rather than in surgical treatment. Two well-known categories include the paranoid patient, usually male, and the hysterical female.

It is generally accepted that elective operations, particularly in the genital region, are to be avoided in paranoid males. The symbolic significance and the distorted interpretations put on such operations by these patients often have led to tragic circumstances. Also well known are the female patients with basically hysterical masochistic personalities and great masculine protest who never seem to rest until all vestiges of their female anatomy are removed. These are the women with incapacitating abdominal and perineal pain who have undergone long series of operations in which their reproductive tracts have been removed piecemeal until they are eventually rendered neutral. However, the pain and animosity toward the surgeon remain unaltered. It is a truism in these cases that surgical procedures fail to relieve the patient of a disabling symptom because an attempt has been made to remove surgically the somatic expression of an emotional illness. Such attempts all too often merely lead to repetition of the symptoms.[1]

Other guides, which perhaps are known but which are not well defined, can help the psychiatrist in aiding the surgeon. The absence of organic findings is not a sufficient reason for establishing a psychiatric or "functional" diagnosis. A common error of our nonpsychiatric colleagues is to label a symptom as psychogenic because examinations did not reveal organic findings. This is a negative approach. Positive psychiatric findings must be obtained to support a psychiatric diagnosis.[2]

Significant Factors in Psychiatric History

If psychiatric opinion is to be based on positive psychiatric evidence rather than on intuition or on absence of organic findings, it is necessary to stress the importance of a carefully taken psychiatric history. Certain areas of the history are of greater significance than others in helping the psychiatrist to formulate his opinion. Several suggestions are presented and will be illustrated later in reports of cases.

Genetic material may reveal a significant person in the patient's environment who had a similar or somewhat similar illness. In these cases it is helpful to know the patient's reaction to that person and to the illness. Many times a hostile identification is made by the patient with this significant person resulting in an almost learned method of reacting to stress by means of illness.

Significant events surrounding the onset or the recurrences of the symptom may be pertinent. Some of the commoner events are death or separation from a parent, spouse, or lover, difficulties in relations with an employer or some parental figure, or threat of illness. Consequently, when taking a detailed history it is necessary to identify not only the members of the patient's immediate family but also the important personal contacts in his business, social, and sexual life.[3]

The symbolic significance of the patient's symptom or involved organ to him is a factor. There are certain portions of the body which are commonly endowed with a great amount of symbolic significance. Already mentioned are the genitalia and the reproductive system. Another common region is the back, and pain in the back is notoriously hard to evaluate. Admittedly, the symbolic significance of a pain or symptom rarely becomes apparent in an initial diagnostic interview, but some clue is frequently obtained when the data are correlated with other material.

Important also are the history of previous illness and surgical experience and the patient's reactions and recovery from them. It is safe to assume that a patient who has undergone three operations on the back for the relief of pain and has had poor results most likely will not benefit from a fourth operation. The tendency to regress seriously and become dependent on narcotics after previous operations should be considered carefully.

The manner in which the patient discusses his symptom is also quite revealing. The bland indifference of the conversion hysteria patient is well known, as is the highly dramatic patient whose symptoms are far out of proportion to the findings. A sensitive, well-trained psychiatrist will note certain more subtle factors, for example, the symptom is often precipitated or aggravated by discussion of topics emotionally distressing to the patient.

The element of secondary gain should be considered. Although this may be unconscious as far as the patient is concerned, it is a real factor. The patient is in need of the symptom to control his environment, as in the case of a woman whose symptom is used as a club to keep an errant husband in line, or, in the frigid woman, as an excuse to avoid sexual relations.

The following condensed reports of two cases will serve to demonstrate some of these points.

Report of Cases

Case 1.—A 38-year-old woman was seen at the Mayo Clinic in 1955, at which time she complained bitterly of incapacitating pain in the back and in the sacral region extending down both legs. She was unable to sit and she walked with cautious mincing steps. An extensive examination was done, and nothing of a positive nature was discovered. The neurologist felt that her disability was far out of proportion to her symptoms and asked for a psychiatric opinion for diagnostic purposes.

Her father was an alcoholic who was abusive to the patient and her mother. The mother was a long-suffering masochistic woman who frequently "took to bed" with pains in the chest when the patient's father was particularly brutal. The patient married a rather passive man, and both were disappointed that she could not have children after removal of both tubes and one ovary, which were said to be diseased. The patient "did not get back on her feet" for one year after this operation, which was done shortly after her marriage. She had always been frigid and had avoided intercourse.

The onset of the pain in her back came on within a short time after she discovered that her husband was having an affair. She acknowledged that since the onset of the pain her husband had been solicitous and remorseful. Also, she had successfully avoided intercourse since the onset of her symptoms. The patient was lying down during the entire interview; she was extremely dramatic and smiled frequently while telling of current excruciating pain.

This history was shared with the orthopedist and neurosurgeon with the strong recommendation that surgical procedures be avoided in that there was overwhelming psychiatric evidence that the patient's problem was an emotional one. Psychotherapy was advised, but the patient refused.

She returned in 1958 with exactly the same complaints and was even more disabled. She had undergone three surgical procedures elsewhere in the interim with no relief and with great venom toward the "incompetent surgeons who operated on me." A conservative program of psychotherapy and physical therapy was outlined for her.

Case 2.—A 54-year-old woman was injured in an automobile accident in 1949 and had persistent pain in her neck and in the lower portion of her back. She complained also of numbness of the right arm. She had spent all but one hour of each day in bed for the previous three years because of the pain. She had undergone two operations elsewhere for removal of a protruded intervertebral disk, and on the second occasion the fourth and fifth lumbar vertebrae were fused. Her recovery from the operations was slow, and she had the problem of addiction to meperidine (Demerol) after the second operation. The examinations revealed some positive neurological findings and narrowed vertebral interspaces in the low cervical and lumbar portions of the spinal column. Operation was considered but was abandoned in favor of a conservative program after completion of the psychiatric study, which revealed a masochistic personality with much secondary gain and control of her environment by means of her symptoms. The lack of success of the previous operations and the psychiatric complications after the second influenced the decision to avoid operation despite the strong evidence of the presence of a pathological condition.

Comment.—The patient in the first case demonstrated hostility and a masochistic attitude toward men, the identification with the mother who had a need for illness, and the onset of the patient's symptoms after discovery of her husband's infidelity. Both patients showed evidence of secondary gain and the control of the environment by means of illness and pain. Both patients also showed poor responses to and results from earlier operations elsewhere. Actual dependence on narcotics was evident in case 2. Both patients exhibited dramatic attitudes with disability being far out of proportion to the findings.

Fortunately, operation was avoided in these two cases, which are prototypes of many similar cases. The existing symptoms would have been further fixed and additional disability would have followed if an operation had been performed.

Negative Results of Psychiatric Examination as Guide to Surgeon

Heretofore I have discussed recognition of patients in whom surgical intervention is contraindicated from the psychiatric standpoint. Of equal help to the surgeon are those cases in which the psychiatric interview used as a diagnostic tool can predict when surgical procedures will be helpful.

Case 3.—A 42-year-old man came to the clinic with a history of recurrent severe pain in the right upper quadrant extending around the right costal margin to the lower edge of the right scapula. Nausea or vomiting was not associated with the pain, and relief was obtained only with narcotics. The pain was sufficiently frequent and disabling to prompt the patient to request exploratory laparotomy. The results of exhaustive tests and examinations were negative, as they had been elsewhere. A psychiatric opinion was requested by the surgeon. The psychiatric examination did not reveal significant psychopathological factors. The patient had an excellent work record, and family and marital adjustments were normal. No precipitating event was found from an emotional standpoint, no secondary gain was apparent, and no typical somatic expression of an emotional conflict was evident in the manner in which the patient discussed his symptoms. These data were recorded on the patient's chart, and the surgeon was notified that the patient's pain could not be ascribed to psychiatric causes and that laparotomy was justified.

At operation a subacute perforating postbulbar ulcer was found, and gastrectomy was performed. The patient made an excellent recovery, returned to work, and has been asymptomatic.

Comment.—It should be emphasized that a history that is void of significant psychopathological evidence as in case 3 is quite different from the bland "everything and everyone is perfect" type of history characteristic of the hysterical personality.

Carcinoma of the pancreas has frequently been diagnosed as a psychogenic illness owing to the unusual nature and pattern of the pain. Here again the psychiatric interview has been helpful in discounting the diagnosis of psychoneurosis, and in a few instances the psychiatrist has actually made the diagnosis of carcinoma of the pancreas.

Psychiatric Indications for Surgical Intervention

Not so well known are cases in which operation will be beneficial to the psychiatric disorder as well as to the organic pathological state. This is particularly true in the depressions encountered among patients in the older age group. It is almost as if the discomfort of the operation is sufficient to assuage the patient's guilt which has been feeding the depression.

CASE 4.—A 64-year-old man was admitted to the psychiatric unit because of depression of several months' duration. The depression had become progressively worse with suicidal thoughts. In addition, the patient gave a history of increasing urinary difficulty indicative of prostatic obstruction. Transurethral prostatectomy was indicated, but the consulting urologist was reluctant to operate in view of the patient's depression. I indicated a preference for having the operation performed before electroshock therapy was undertaken in the hope that the depression would be lessened. Prostatectomy was performed, and the result was excellent. The patient was relieved of depression to the extent that electroshock therapy was avoided and he returned to his job.

Comment.—Obviously surgery cannot be endorsed as psychiatric therapy, but in a few carefully selected cases it can be helpful. Also in this category are those cases in which the surgeon feels an operation is indicated but is reluctant to operate due to a previous or current serious psychiatric diagnosis. Many physicians are of the opinion that psychiatric patients generally will have a difficult postoperative course because of the emotional decompensation as a result of operation. By and large, the reverse is true. Patients with diagnoses of schizophrenia and depression, for example, are not as brittle as is often thought; in fact, they seem to meet the stress of surgical procedures with surprisingly good ego strength.

CASE 5.—A 32-year-old housewife had been hospitalized on several occasions with a diagnosis of schizophrenia. This diagnosis was made at the age of 24 years, and since that time the patient had been able to function at home relatively well between relapses. She had three children and had had postpartum schizophrenic relapses after the first two deliveries. She was seen psychiatrically during the third pregnancy as she feared a relapse. However, she got along unusually well during her pregnancy and the postpartum period except for some mild gnawing abdominal pain which she ascribed to her pregnancy. When the pain persisted after delivery, a roentgenogram of the stomach was made, which revealed a huge prepyloric gastric ulcer on the posterior wall of the stomach. In view of the psychiatric history, the internist and surgeon felt that nonsurgical management would be best, although a surgical procedure would be the treatment of choice. The psychiatric opinion was to the effect that the patient would probably withstand operation satisfactorily, especially in view of her ability to carry through her pregnancy and delivery without decompensating. Consequently an operation was performed; carcinoma of the stomach was discovered, and the lesion was removed. The patient withstood the operation well and also accepted the diagnosis in a realistic manner. She was able to function in a most satisfactory fashion postoperatively as determined by psychiatric follow-up.

Comment.—Psychiatrists are aware of numerous instances of remissions from schizophrenia that have occurred after the stress of serious surgical measures. The general tendency to avoid operation when there has been a history of psychiatric decompensations is not warranted.

Summary

Psychiatrists are in a unique position to assist the surgeon in cases of elective operation by properly evaluating the patient's symptoms by means of a careful psychiatric history. There are guideposts for the use of accepted principles to replace intuition. Psychiatric consultation is valuable not only in cases in which operation is contraindicated from the psychiatric viewpoint but also in those cases in which operation will prove to be helpful.

CINEMATOGRAPHY OF HUMAN RETINAL VESSELS

A PRACTICAL CLINICAL AND RESEARCH TECHNIQUE

Paul Bailey Jr., M.D.
and
Kenneth C. Swan, M.D., Portland, Ore.

In recent years, functional changes in the retinal vessels and other structures of the fundus have become increasingly important to clinicians and others. Changes not readily discernible with ophthalmoscopy or serial still photography can be demonstrated by a practical technique of cinematography designed and in use at the University of Oregon Medical School. With a special camera, variations in amplitude, character, and rhythm of pulsation of the retinal arterial system can be detected for research and teaching purposes, and to aid in differential diagnosis, or to permit early evaluation of therapy. The camera contains three basic units: a mounted +20 D. condensing lens, a light source with means of changing magnification, and the camera body containing film and a continuous focusing device.

Ophthalmoscopy has become a part of the routine general physical examination; however, fundus studies with the hand ophthalmoscope primarily have been directed toward the recognition and evaluation of morphologic changes in the retinal vessels and other structures of the fundus. These changes generally can be recorded satisfactorily with commercially produced cameras which take single-frame pictures. In contrast, functional changes such as in the character and amplitude of pulsation of the retinal vessels or in the movement of blood through them have received relatively little attention. In recent years these functional changes have become increasingly important to clinicians and investigators in several fields of medicine, but there has not been a satisfactory way to record these alterations for research, teaching, or records of individual patients. For example, in systemic vascular disease such as atherosclerosis, early clinical manifestations are difficult to detect; therefore, criteria for evaluation of therapy early in the course of the process generally are inadequate. An effort has been made to recognize changes in elasticity or reactivity of the retinal vessels as possible early manifestations of systemic vascular disease. In hypertensive disease, Sieker and Hickam [1] have evaluated this factor by studying the constriction and dilatation of the retinal arterial tree while the patient breathed oxygen. They have demonstrated these changes by still photographs of the fundus, but in our experience alterations in caliber and amplitude of pulsation are more readily discernible in cinematography.

Another indication for study of the retinal vessels, of particular importance to neurologists and neurosurgeons, has been occlusive disease involving the carotid system. In occlusion of the internal carotid artery there is a decreased amplitude of pulsation of the retinal arterial system. This sometimes can be measured by ophthalmodynamometry. Unilateral alterations in the amplitude of pulsation of the retinal vessels also occur in carotid-cavernous sinus communication and in some basilar aneurysms. Alteration in amplitude of the retinal venous pulse is of value in the differential diagnosis of papilledema. In true papilledema, in contrast to pseudo-papilledema, there is absence or decrease in venous pulsation at the optic disk. From the viewpoint of the ophthalmologist concerned with ocular disease, the relationship of the retinal and choroidal arterial circulation to the intraocular pressure and to changes which take place in inflammatory disease needs to be more thoroughly investigated.

From examples cited above it is evident that a practical technique of cinematography to record the pulsations in the retinal circulation would be valuable for recording changes in the individual patients and for research purposes. From the viewpoint of teaching ophthalmoscopy to undergraduates and physicians, fundus cinematography has proved to be an important adjunct at the University of Oregon Medical School.

The major reason for the limited use of cinematography since Pavía [2] called attention to it in 1952 has been the technical difficulty involved in taking these pictures. The tolerance of the human eye to light is limited. Furthermore, high concentrations of visible light are capable of producing irreversible damage to the retina, e. g., eclipse blindness.

Several approaches have been made to this problem. In experimental animals it has been possible to remove the anterior segment of the eye and replace it with a glass surface. This technique was used by Ashton [3] in recording the changes induced in the retinal vessels in the kitten eye by systemic administration of oxygen. Another technique which we have used until recent years has been to add a movie film carrier to the Nordenson type of fundus camera. This system does not permit continuous

---

From the Department of Ophthalmology, University of Oregon Medical School.

focusing and is too inefficient to obtain consistently good films even with high-speed film. Still another technique has been to use a television camera and to record film from the face of the television tube.[4] It seemed to us that if cinematography were to be made useful as a clinical and research tool, it would be necessary to design a camera which could be produced at a reasonable cost and which could be used with a majority of patients. Such a camera has been designed at the University of Oregon Medical School and has been used since 1957.

The camera contains three basic units. The first unit consists of a mounted +20 D. condensing lens as is used in indirect ophthalmoscopy. The second unit contains a light source and a means of changing magnification. It consists of the body of a Zeiss dissecting microscope. This particular microscope provides a range of four magnifications. Also, it contains a built-in filter system and an efficient source of para-axial illumination. The light is directed through the condensing lens and pupil at a slightly oblique angle. The third unit consists of a camera body which carries film and contains a continuous focusing device. For continuous focusing, it is almost essential to have a through-the-lens system such as is provided by the 16-mm. Arriflex camera. No light is lost by this system and it permits the operator to shift the field, to vary the magnification, and to keep the camera in accurate focus while the photography is being continued. The camera system is shown diagrammatically in figure 1.

ADJUSTABLE FILTER

Fig. 1.—Camera system for fundus cinematography.

No special film is required. Currently we are using a high-speed color film manufactured by the Ansco Company under the trade name of Super Anscochrome. This can be developed at its usual speed of ASA 100. Satisfactory prints can be made in black and white or color from this film.

The technique of fundus cinematography is similar to that used for still photographs of the fundus. It is essential that the pupil be widely dilated and that the patient cooperate by keeping his head and eyes reasonably stationary. The camera in use with an ambulatory patient is illustrated in figure 2; however, the camera is portable and can be mounted on a standard tripod for use with reclining patients. In the past year film studies have been made of a diversity of conditions. It has been found that the cinematography records satisfactorily nearly all of the functional changes in the retinal vessels which can be observed with a hand ophthalmoscope. In addition, the magnification gained when these changes are projected on the screen frequently brings out alterations in the character of the pulsations which are not discernible even with a binocular ophthalmoscope. Another important observation has been that an amplitude of pulsation or a shift in position of a segment or vessel which may be easily discernible when the movie films are projected may not be evident with serial prints made from the film.

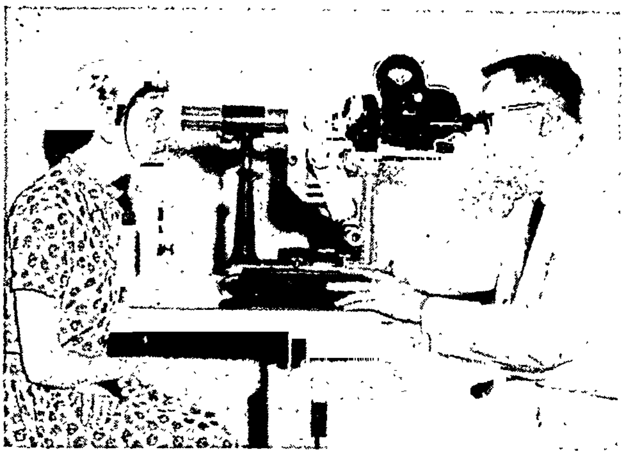

Fig. 2.—Camera system assembled for fundus photography in average ambulatory patient. System can be moved as unit or component parts adjusted separately for varying circumstances.

Films are being made to illustrate variations in the pulsation in normal eyes, in hypertensive disease, in various stages of atherosclerosis, and in disturbances in the carotid circulation. Particularly dramatic changes have been recorded in patients who have cardiac disease with arrhythmias and abnormal pulse pressure. Figure 3 illustrates the vari-

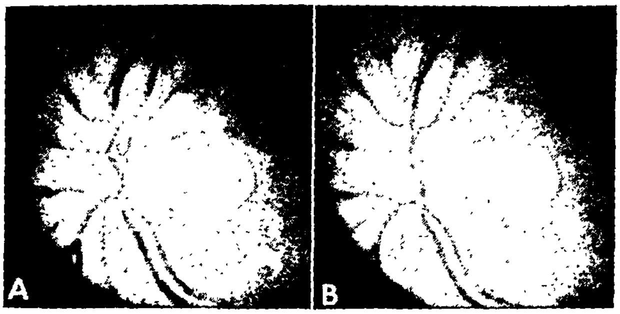

Fig. 3.—Prints made from 16-mm. color film showing that during diastole (*A*) there is filling of veins of optic nerve head, whereas during systole (*B*) transmission of arterial pulsation through vitreous results in marked blanching of veins in center of disk. Patient has aortic valvular insufficiency.

ations in the venous pulsation in the disk which were recorded in the film of a patient with aortic valvular insufficiency. Since the arterial pulsation is transmitted through the vitreous to the retinal veins, the changes seen in the venous system are more dramatic than those in the arterial tree.

Films taken at the University of Oregon Medical School already are in use in student teaching and have proved particularly effective in demonstrating the loss of elasticity in sclerotic disease, in showing such unusual circumstances as the streaming of the red blood cells in the central retinal vessels in central retinal artery occlusion, and in demonstrating the influence of external pressure on the globe as in ophthalmodynamometry.

Summary

A practical camera and technique for retinal cinematography has been designed and is in use at the University of Oregon Medical School to record the functional changes which take place in the retinal vascular system in normal eyes and in the fundus of patients with certain ocular diseases, systemic vascular diseases, or alterations in the carotid circulation. Changes can be demonstrated which are not discernible with ophthalmoscopy or serial still photographs. The movie films have proved to be an excellent aid in the teaching of ophthalmoscopy and in making progress studies in individual patients in several fields of medicine.

3181 S. W. Sam Jackson Park Rd. (1) (Dr. Swan).

The studies reported were conducted under a grant from the Oregon Heart Association.

"DIAGNOSTIC SMALL THORACOTOMY" IN IDIOPATHIC PLEURAL EFFUSION

Frank T. Lansden, M.D.
and
William H. Falor, M.D., Akron, Ohio

Exploratory thoracotomy with pleural biopsy was performed in 17 patients who had idiopathic pleural effusions. In each case the operation was done because the usual procedures of thoracentesis, sputum examination, bronchoscopy, and scalene lymph node biopsy had failed to settle the diagnosis. The thoracic cavity was entered by an incision not exceeding 20 cm. in length through the sixth, seventh, or eighth interspace, which permitted exploration of the corresponding half of the thoracic cavity and removal of biopsy specimens. The diagnoses were postpneumonic effusion in seven cases, carcinoma in six, sarcoma in one, tuberculosis in two, and lymphoma in one. Two cases are described in detail to illustrate chronic tuberculous pleurisy in one patient and lymphoblastoma in the other. This method of "small thoracotomy" is suggested for cases in which idiopathic effusions remain unexplained after careful medical and laboratory examinations.

The term pleurisy with effusion has come to be used synonymously with tuberculous pleurisy. This is understandable, as in 30 to 50% of these cases Mycobacterium tuberculosis can be cultured from the thoracentesis fluid. Even higher percentages may be obtained if a guinea pig is inoculated with the fluid. Statistics have shown that roughly 50% of patients with an idiopathic effusion will develop active pulmonary tuberculosis within five years if not treated. While these figures are representative in the younger age groups, such is not the case with older persons. Here, multiple causal factors must be considered and a strong suspicion of primary and metastatic malignancy entertained. It is both unfair and unwise to assume that all sterile pleurisy is due to tuberculosis, especially among older persons.

Other causes of pleural effusion are numerous. However, there is usually sufficient clinical history, when coupled with positive physical findings, to establish the diagnosis.

Although pleural effusion is frequently an initial sign of a disease process, its etiology is often obscure and only recognized with the later appearance of

---

From the Surgical Department, Akron City Hospital.

more obvious signs of the disease. In spite of a barrage of laboratory and radiologic examinations, the early diagnosis may be delayed and the proper therapy instituted in a later stage of the disease, when the patient is less responsive to treatment.

Initial diagnostic laboratory procedures for idiopathic pleural effusion should include bacteriological studies of the centrifugated residue of the entire mass of aspirated fluid. Subsequent studies in obscure cases should include specific intradermal tests along with examinations of sputum for pathogens and neoplastic cells. When results of these tests have been negative or inconclusive, bronchoscopy with aspiration biopsy and transbronchial subcarinal lymph node biopsy have sometimes provided the answer. Local excision of a scalene, mediastinal lymph node is easily accomplished with the patient under local anesthesia and can be readily integrated into the program of diagnostic procedures. It has been our policy to employ all of these methods, in addition to repeated examinations of the thoracentesis fluid, in all cases of undiagnosed pleural effusion. If the etiology remains obscure after application of these steps, surgical exploration of the pleural space is both indicated and desirable.

Exploratory thoracotomy is not yet as well accepted as exploratory laparotomy and is erroneously considered by many to be a formidable procedure. Actually, the morbidity and mortality from thoracic exploration is far less than that for abdominal exploration, and its application deserves much more attention than it has been previously given.

The purpose of this report is to present experience with 17 cases of exploratory thoracotomy and pleural biopsy in patients with idiopathic pleural effusion. Two cases are presented in detail and the results of the remaining 15 are summarized.

Procedure

The patients selected for this report were adults of varying ages with idiopathic pleural effusions. Each presented a problem in diagnosis or treatment. All of the patients were thoroughly studied by means of thoracentesis, sputum examination, bronchoscopy, and scalene lymph node biopsy prior to surgery.

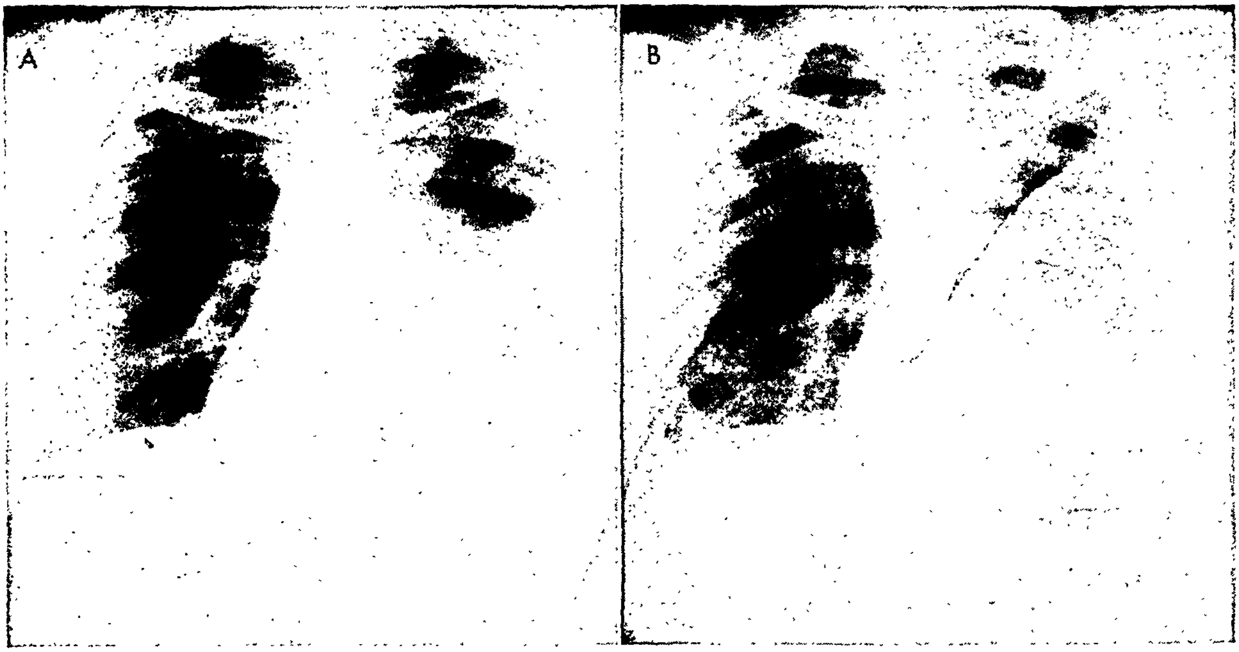

Fig. 1 (case 1).—*A*, posteroanterior view of chest prior to thoracentesis. Note huge left pleural effusion with essentially normal right lung. *B*, posteroanterior view of chest after thoracentesis. Note thickened pleura and obtunded costophrenic sulcus.

The thoracic cavity was entered through the sixth, seventh, or eighth interspace on the appropriate side. The size of the incision was held to a minimum, 6 or 8 in., but in all cases allowed the introduction of the examining hand and a small self-retaining retractor. The entire thoracic cavity could be explored with ease, and adequate biopsy specimens of the involved portions could be taken. In the event that definitive surgical treatment was indicated the incision could readily be extended to permit adequate manipulation of the thoracic contents. Thus, in many cases, exposure was sufficient to establish a diagnosis and yet produce a minimum of postoperative distress. This limited thoracotomy, established in as dependent a portion of the thorax as was consistent with the location of the effusion, was termed a "diagnostic small thoracotomy."

Report of Cases

CASE 1.—A 35-year-old man was admitted to the hospital on Aug. 24, 1957, with complaints of cough and pain in the left side of the chest of one week's duration. He stated that he had had chills and fever on several occasions. Physical examination revealed dulness and absent breath sounds in the left base. X-ray studies substantiated the presence of a massive pleural effusion on the left (fig. 1*A*), and thoracentesis was accomplished. Cultures of this fluid and of the sputum revealed no evidence of M. tuberculosis and the result of the tuberculin skin test was read as negative. After two weeks of therapy and repeated thoracenteses x-ray studies revealed multiple fluid levels and total pneumothorax. Candida and many bacteria were cultured from the chest fluid and sputum, but no evidence of tuberculosis or malignancy was detected. Upper and lower gastrointestinal series were noncontributory. On Sept. 12, 1957, bronchoscopy and scalene lymph node biopsy were undertaken and normal reports returned. Six days later a small thoracotomy was done on the left. The left lung was found to be almost totally collapsed, with a large abscess cavity in the lower lobe. A dense fibrinous peel covered the lung. The pleura was studded with small yellow lesions resembling those of tuberculosis, and there were multiple pockets of yellow fluid present. The lung was decorticated and rose to fill the chest cavity (fig. 1*B*). Biopsy was then performed on a specimen from the pleura (fig. 2) and the chest was closed. The pathologist returned a diagnosis of chronic tuberculous pleurisy and the patient was transferred to a sanitarium for further treatment.

CASE 2.—A 39-year-old woman was admitted to the hospital in August, 1957, with a pleural effusion. She was entirely asymptomatic at that time and knew of no exposure to tuberculosis (fig. 3*A*). Thoracentesis produced about 1,500 cc. of milky fluid resembling chyle. Smears and cultures of this fluid were noncontributory, except that 0 to 1 acid-fast bacilli were reported per high-power field (fig. 3*B*). Results of skin tests for tuberculosis were negative, and the patient showed no further evidence of disease. Bronchoscopy and scalene lymph node examination were done and were reported to be normal. The patient was discharged from the hospital after careful observation during which time the effusion did not recur. She was readmitted to the hospital in November, 1957, with evidence of recurrence of fluid but still completely asymptomatic. Thoracentesis again produced 500 cc. of chylous fluid which was examined and reported as negative for bacteria and tumor cells. The only other significant item in the patient's history was that of removal of a benign rectal polyp three years prior to admission. On Nov. 26, 1957, a small thoracotomy was performed on the left side. Some chylous fluid was again noted in the pleural cavity. The lung, mediastinum, and great vessels appeared normal. There was evidence of enlargement of the aortic lymph nodes, and a tumor mass, roughly 3 by 5 cm., was found retropleurally in the left paravertebral area. This tumor appeared to be in the area of the thoracic duct and apparently invaded the sympathetic chain in this area. A biopsy specimen was taken from the mass (fig. 4) and the chest closed. The pathologist reported lymphoblastomatous transformation of a lymph node with invasion of sympathetic ganglions and nerves.

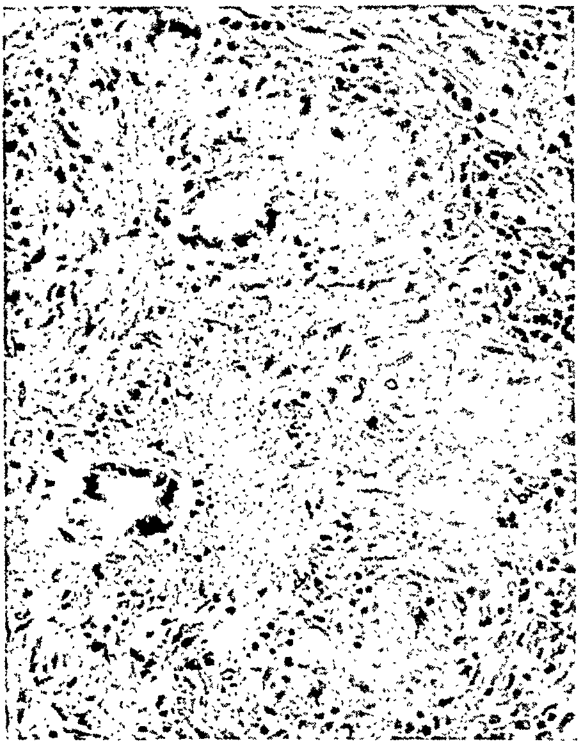

Fig. 2 (case 1).—Low-power view of biopsy specimen. Note central area of necrosis surrounded by multinucleate giant cells. Results of skin tests and laboratory examinations on sputum were negative.

Of 17 consecutive patients, including the 2 whose cases are summarized above, the pathological diagnoses proved by small thoracotomy were postpneumonic effusion in 7; carcinoma in 6; sarcoma in 1; tuberculosis in 2; and lymphoma in 1.

Comment

In 1949 Klassen[1] introduced the term "small thoracotomy" to describe the limited incision employed in the diagnosis of diffuse pulmonary lesions. The utility of this procedure has been increased by adapting it to other undiagnosed intrathoracic lesions. Breckler and co-workers[2] reported on 16 consecutive cases of open pleural biopsy in which an anterolateral incision at the eighth interspace was used. They found that this method had definite advantages over the needle biopsy methods proposed by Heller and co-workers[3] and quickly abandoned the latter. In two cases exploration afforded a diagnosis which could not have been easily made by any other means. Of 10 suspected cases of pulmonary tuberculosis with effusions 9 were proved histologically.

Sutliff and co-workers[4] studied the problem of pleural effusion by open biopsy technique through a 6-in. posterior incision at the eighth interspace. A small segment of rib was removed in each case. In a series of 21 cases 17 were found to be due to tuberculosis, 3 to carcinoma, and 1 to North American blastomycosis. Similar results were reported by Small and Landman[5] who reported on five cases of open pleural biopsy with palpation of the lung and pleura. These were all suspected to be due to tuberculosis, and the diagnosis was proved histologically in all cases by this manner.

Diagnostic thoracotomy for pleural effusion has been performed by Douglass and co-workers[6] who reported on 21 cases. The authors described the relative merits of the procedure and concluded that thoracotomy was a valuable aid in the diagnosis of these effusions. Of the 21 cases presented, 6 were found to be caused by neoplasm, 1 was attributed to trauma, 5 showed histological evidence of tuberculosis, 7 were due to other inflammatory processes, and in 2 the cause was indeterminate.

Exploratory thoracotomy is not a new thing, but some trepidation still exists when surgeons suggest thoracotomy as a diagnostic procedure. Conservative medicine is not always the best medicine, however, and many hospital days and much morbidity can be saved when guesswork is eliminated. In our hospital idiopathic effusions are treated conservatively, at first, but when we have failed to arrive at a tenable diagnosis after careful medical and laboratory examination we suggest small thoracotomy. Mortality and morbidity are quite low. The diagnosis and prognosis are established and definitive therapy is not infrequently carried out during employment of such a diagnostic small thoracotomy for pleural effusion.

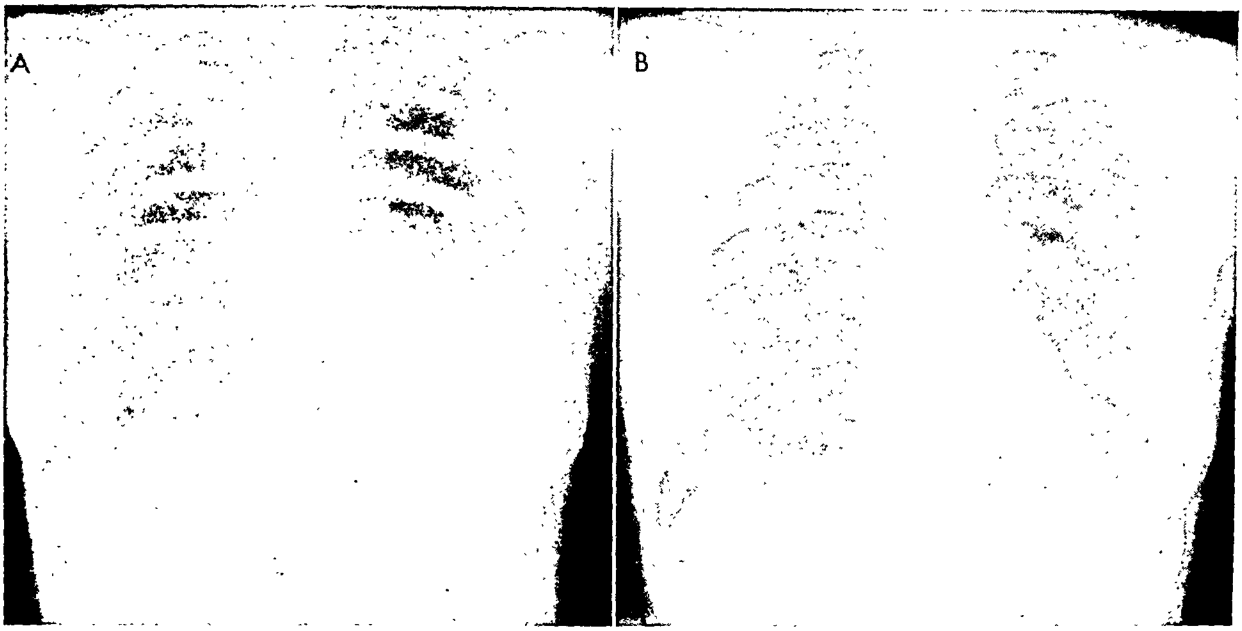

Fig. 3 (case 2).—*A*, posteroanterior view of chest prior to thoracentesis. Note large left pleural effusion and otherwise normal appearance. Patient was entirely asymptomatic. *B*, posteroanterior view of chest after thoracentesis produced 1,500 cc. of chylous fluid. Results of skin tests for tuberculosis were negative.

Summary

The pathological diagnosis was established by small thoracotomy and biopsy in 17 consecutive patients with idiopathic pleural effusion. This

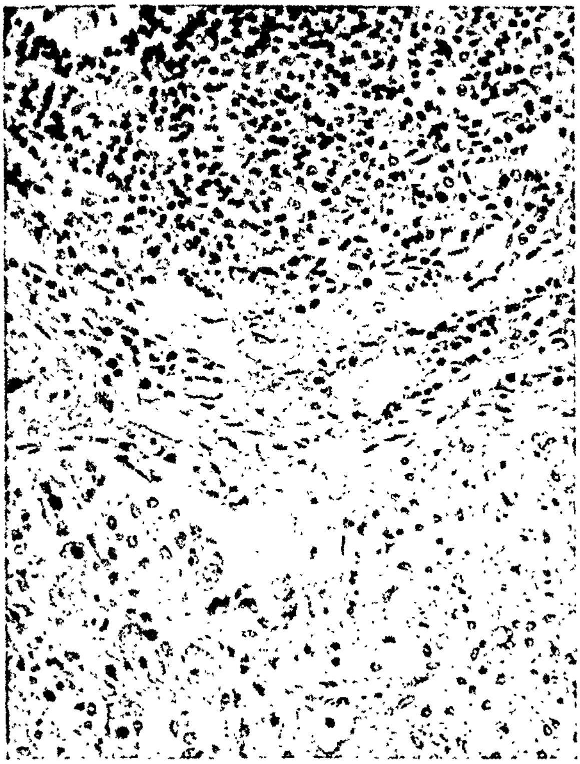

Fig. 4 (case 2).—Low-power view of biopsy specimen. Note extensive small cell infiltration of specimen. Large cells in lower left are cell bodies of sympathetic ganglions in this area. There was no histological evidence of tuberculosis.

method has definite advantages over other methods in that the entire disease area can be observed, palpated, examined by biopsy, and, where practical, treated. Many hospital days and much morbidity can be eliminated when the etiology of the effusion is ascertained and definitive therapy is started. The establishment of prognosis is an invaluable by-product of the procedure.

550 E. Market St. (4) (Dr. Falor).

Histological and laboratory examinations were done by the Department of Pathology, Akron City Hospital, under the direction of Lloyd Catron, M.D. Photographs were made by Mr. John A. Muldowney.

ATTITUDES TOWARD GROWING OLDER.—This study of attitudes toward aging is based upon interviews with a sample of 625 men and women aged 40 to 70 residing in the metropolitan area of Kansas City. The group constituted a random sample of individuals (not married couples) drawn by area-probability technics and stratified by age, sex, and social status. The sample was approximately equally divided between men and women as well as among persons of each of four social-class levels. . . . Data were gathered in connection with a larger study, the Kansas City Study of Adult Life. In an extensive interview . . . a number of questions were asked regarding attitudes toward the present and toward the future. . . . There was a striking consistency in the content of responses about the future. For those persons expressing negative or contingent attitudes toward the future, the fear of some form of dependency is paramount. They say: "Growing old is terrible, because somebody has to take care of you," or "I don't mind growing old as long as I don't become a burden to others." Dependency in turn is always seen as having two sources—loss of income and loss of health. Seldom is one mentioned without the other. Fear of death is never alluded to, nor is fear of social isolation. Illness, blindness, and deafness are seen not as threats to bodily integrity, but as states involving dependence upon others. This triad—dependency, loss of health, and loss of income—was the only theme to occur with any frequency. It is of special interest that the incidence of this response was approximately the same for men as for women, for the different social classes, and for people at all ages. Since the 40-year-old mentions the dependency triad as frequently as does the 60-year-old, it appears that he interprets the question about growing older as referring to a period of "being aged," and not to the near or relatively near years of the 50s and 60s. Thus, for all people, "becoming older" does not appear problematic—it is "being old" that has meaning.—B. L. Neugarten, Ph.D., and D. C. Garron, Attitudes of Middle-Aged Persons Toward Growing Older, *Geriatrics,* January, 1959.

NEW ANTIBODY (ANTI-Rh^B) RESULTING FROM BLOOD TRANSFUSION IN AN Rh-POSITIVE PATIENT

Lester J. Unger, M.D., Alexander S. Wiener, M.D.
and
Leo Weiner, M.D., New York

Clinicians are well aware that erythroblastosis fetalis (hemolytic disease of the fetus and newborn) results from an incompatibility of the blood of the baby for the mother's serum, while hemolytic transfusion reactions are due to incompatibilities between patient's and donor's bloods. Many blood factors exist, and, therefore, many different kinds of incompatibilities are possible. In fact, it is hardly possible to transfuse blood that is identical in all its blood factors with that of the patient. To do so would necessitate that some 150,000 varieties of blood be kept constantly available, whereas, at present, blood banks stock only eight different varieties. It is the purpose of this paper not to elaborate on the details of this complicated immunohematological subject but, rather, to call attention to and to clarify one puzzling situation.

As explained in a previous report,[1] in recent years a number of cases have been encountered in which patients who had had hemolytic transfusion reactions and mothers of erythroblastotic babies were found to be Rh$_o$-positive yet had antibodies in their serum resembling anti-Rh$_o$ in specificity. This constituted a paradox, since, theoretically and in practice, it had been found that only Rh$_o$-negative persons can be sensitized to the Rh$_o$ factor. Closer study then disclosed that the antibodies in these patient's serums were actually not identical with Rh$_o$, since they failed to react with the red blood cells of the patients as well as cells from certain other rare Rh$_o$-positive persons. Comparison of the antiserums from different Rh$_o$-positive patients so sensitized showed that the antibodies differed not from anti-Rh$_o$ but from one another. Therefore, they had to be assigned distinctive symbols, and we have used the designations anti-Rh^A, anti-Rh^B, anti-Rh^C, etc., in rotation for the antibodies we studied. It is now clear that in the Rh agglutinogens associated with factor Rh$_o$ there are multiple blood factors other than Rh$_o$, namely, Rh^A, Rh^B, Rh^C, etc. (The Rh agglutinogens include all agglutinogens having in common factor Rh$_o$, namely, agglutinogens Rh$_o$, Rh$_1$, Rh$_2$, and Rh$_z$). In certain rare Rh-positive persons, one or more of these factors may be lacking, and such persons can be sensitized to the missing factor or factors. As has been explained, the resulting antibody which is formed, anti-Rh^A, anti-Rh^B, or anti-Rh^C, as the case may be, simulates anti-Rh$_o$ in specificity.

A woman, aged 57, received four blood transfusions at various times during a period of three months before, during, and after surgery. Before each transfusion the prospective donor's blood was shown to be compatible by an unusually elaborate series of tests; yet the first two transfusions were followed by chills and fever, presumably because of some unrecognizable incompatibility. The results led the authors to the conclusion that in Rh-positive blood, associated with the Rh$_o$ factor, there are other blood factors which they designate Rh^A, Rh^B, Rh^C, etc. The complications in this case could be explained when it became possible to demonstrate in the patient's serum the presence of a new antibody, which they designate as anti-Rh^B.

Wiener and co-workers[2] studied the serum of a type Rh$_1$rh mother who gave birth to an erythroblastotic type Rh$_1$rh baby. To the antibody in the mother's serum they assigned the symbol anti-Rh^A. Two of us (L. J. U. and A. S. W.) have reported the results of extensive studies[3] on blood factor Rh^A and a similar case involving twin erythroblastotic babies.[4] To the factor in the latter case the symbol Rh^C has been assigned and to the antibody anti-Rh^C. The present paper deals with a hemolytic transfusion reaction in an Rh$_o$-positive patient caused by Rh sensitization. To the antibody in this case the symbol anti-Rh^B has been assigned.

Report of a Case

The patient, a 57-year-old Italian woman weighing 103 lb. (46.7 kg.), was hospitalized in August, 1957, as a patient of Dr. L. M. Rosati, with the diagnosis of Laennec's cirrhosis, fatty stage. She had had three children, all living and well. There had been no miscarriages or stillbirths. Previous operations were appendectomy and uterine suspension, but there was no history of previous blood transfusions. Her present complaint was pain in the right upper quadrant of the abdomen.

Physical examination revealed an enlarged, firm, but not tender liver and spleen, both being palpable 3 fingerbreadths below the costal margin. The patient did not have jaundice. The results of both cholecystography and cholangiography were negative. Laboratory findings were as follows: hemo-

---

Director, Blood and Plasma Bank, New York University–Bellevue Medical Center (Dr. Unger); Senior Bacteriologist (Serology), Office of the Chief Medical Examiner, New York City, and Attending Immunohematologist, Jewish Hospital of Brooklyn, N. Y. (Dr. Wiener); and Associate Professor of Clinical Medicine (Hematology), New York University–Bellevue Medical Center (Dr. Weiner).

globin level 11.9 Gm.%; red blood cell count 5,600,000 per cubic millimeter; white blood cell count, 5,600 per cubic millimeter, with polymorphonuclear cells 51%, lymphocytes 38%, monocytes 2%, and eosinophils 9%; total protein level 7.4 Gm. per 100 cc., with albumin-globulin ratio 1.6; prothrombin time 13 seconds; total bilirubin level 0.7 mg. per 100 cc.; and sulfobromophthalein retention 16% (normal up to 5%).

While in the hospital the patient was afebrile. No blood transfusions were administered, and the only treatment given was a diet supplemented with vitamins. She was discharged from the hospital but readmitted two and one-half years later because of hematemesis and tarry stools. Her liver and spleen were now palpable 5 fingerbreadths below the costal margin. X-ray examination revealed esophageal varices. Her hemoglobin concentration on the day of admission was 7.8 Gm.%. The examination of her blood showed it to be group B, Rh-positive. Blood transfusion was ordered and 1,000 cc. of group B, Rh-positive blood administered. Twenty days later a second transfusion was given, 500 cc. of group B, Rh-positive blood. Fifty-one days after admission, a portacaval shunt operation and cholecystectomy were performed. During the operation an ice mattress was used and the patient's temperature lowered to 95 F (35 C). While under anesthesia in the operating room and recovery room, she was given a third transfusion of 1,500 cc. of group B, Rh-positive blood. At the time of operation, the portal pressure was 480 mm. of saline solution, indicating portal hypertension. After the shunt was performed, the portal pressure dropped to 225 mm. of saline solution. Biopsy of the liver disclosed portal cirrhosis. Four days postoperatively, she received a fourth transfusion, this time of group B, Rh-negative blood. She was discharged from the hospital three months after admission.

Results of Blood Tests

The routine procedure for crossmatching used at this hospital includes both major and minor crossmatching, as well as tests on a mixture of patients' serum with patients' own cells carried out by three different methods, namely, saline agglutination, albumin-plasma conglutination, and antiglobulin techniques. In addition to these pretransfusion compatibility tests, sensitivity tests are carried out to detect any atypical antibodies which may be present in the serums of patient and donor. For these sensitivity tests, as test cells, a pool of type Rh_zRh_0 cells, both untreated and treated with ficin, is used with the saline agglutination and antiglobulin methods. The latter method, namely, ficinated-cell antiglobulin, was first described by one of us (L. J. U.) [5] and is the most sensitive of all. Prior to each blood transfusion, a freshly drawn specimen of the patient's blood is obtained for use in the pretransfusion tests.

Before the first blood transfusion was given to this patient, the results of all the tests were negative and the donors' bloods were considered to be compatible and were, therefore, administered. Nevertheless, the patient experienced a post-transfusion chill and her temperature rose to 104 F (40 C). Since no in vitro incompatibility could be demonstrated, since there was some post-transfusion rise in the hemoglobin concentration and erythrocyte count, and since there was neither hemoglobinuria nor any immediate rise in blood bilirubin concentration, this reaction was interpreted as pyrogenic in nature. When the patient's serum bilirubin concentration rose two weeks later and she had mild jaundice, it was natural to ascribe this to the diagnosed cirrhosis of the liver, especially since the question of some degree of jaundice had been raised at the time of admission. Also considered at this time were the possibilities of hepatitis superimposed on cirrhosis of the liver, autohemolytic anemia, and hypersplenism.

About three weeks after admission, the second blood transfusion was given, after the donor's blood was shown to be serologically compatible by all the tests previously mentioned. It is interesting that a weak reaction was reported in the sensitivity tests when the patient's serum was screened for atypical antibodies, but only by the highly sensitive ficinated-cell antiglobulin method. The blood found compatible by the crossmatching tests was administered. This second transfusion was also followed by a severe chill and fever. A direct antiglobulin test on the patient's red blood cells then showed a positive result of 1+, but this was interpreted as due to autoantibodies because a similar 1+ reaction was obtained at this time when the patient's serum was tested against ficinated type rh, type rh′ and type rh″ cells. In retrospect, it seems more probable that the direct antiglobulin reaction was due to surviving donor's cells coated with the offending antibody in the patient's serum. The positive result of the direct antiglobulin test persisted for at least nine days after this second transfusion and possibly longer, since the test was not repeated until another month had elapsed, at which time the result was again positive. From the results of the blood bilirubin determinations and blood cell counts (table 1), the major portion of the blood given at the second transfusion must have been eliminated promptly, in contrast with the slow elimination of the blood of the first transfusion, and the balance was eliminated more slowly, as indicated by the persistence of the positive direct antiglobulin reaction—unless the latter was, in fact, due to autoantibodies. Again, no hemoglobinuria occurred and kidney function was apparently unimpaired.

One month later, prior to operation, the same crossmatching tests were again carried out and in vitro compatible blood selected. In these tests, made by a technician on duty at night, no unusual reactions were noticed. No clinical symptoms were observed after this transfusion, but the patient was under refrigeration anesthesia, which could have suppressed any reaction which might otherwise have occurred. There was a post-transfusion rise in temperature, but this could be ascribed to the operation itself. The blood administered at this transfusion was promptly eliminated, because, after an initial rise, the hemoglobin concentration became lower than before transfusion and there was a simultaneous sharp rise in serum bilirubin concentration. Again, there was no impairment of kidney function, although the nurse noted on the chart the passage of "dark" urine.

TABLE 1.—*Clinical Laboratory Findings*

6/10	9.4		10.47	
7/10				Direct antiglobulin test result negative

*In a few instances, for compactness, tests performed within a few days of one another are recorded as if they were done on same day.

After the operation, when a fourth transfusion was requested, crossmatching tests for the first time gave a 1+ reaction by the antiglobulin technique. This occurred in the minor match as well as in the major match, and the same degree of clumping was observed by the antiglobulin technique in a mixture of the patient's cells with her own serum, so that the reaction obtained could be attributed to autoantibodies. However, a 2+ result in the sensitivity test for atypical antibodies in the patient's serum, with use of pooled Rh_2Rh_0 test cells by the ficinated-cell method, and a 3+ result by the ficinated-cell antiglobulin method caused the technician to withhold blood for transfusion. When the crossmatching tests were carried out with Rh-negative blood no incompatibility was detected, so for this transfusion group B, type rh blood was used and no untoward reaction resulted. After this, the patient's condition improved and she was then discharged from the hospital.

"Standard" Rh	+	+	+	+

* Data from Unger and Wiener.[3a]
† Serum from a Rh_0-negative person sensitized by blood factor Rh_0.
‡ Rh-positive person, not sensitized.

The patient's blood was then studied by two of us (L. J. U. and A. S. W.). Her blood group proved to be B, type Rh_2rh, and in her serum a new antibody was found. Differential agglutination tests showed no evidence of survival of donors' cells from the transfusions she had received. To the particular antibody in the serum of this patient was assigned the symbol anti-Rh^B. Table 2 shows some of the differences in specificity of anti-Rh^A, anti-Rh^B, and anti-Rh^C. That the antibody in the present patient's serum is not anti-Rh^A or anti-Rh^C follows from the fact that the patient's red blood cells, with which her antibody does not react, react with anti-Rh^A serum and also with anti-Rh^C, and to approximately the same titer as with "standard" Rh-positive red blood cells.

TABLE 3.—*Titration Results of Patient's Serum (Anti-*Rh^B*)*

	Rh-Hr Type of Cells Used and Titer, Units*								
	1†			2‡			3§		
Method of Titration	Rh_1-rh	Rh_2-rh	rh	Rh_1-Rh_1	Rh_2-rh	rh	Rh_1-Rh_1	Rh_2-Rh_2	rh
Saline agglutination	0	0	0	0	0	0	0	0	0
Albumin-plasma conglutination	0	0	0	16	16	0	64	64	0

* Units = reciprocal of highest dilution of serum giving 1+ reaction (all test cells used were group O).
† Blood specimen drawn prior to last transfusion.
‡ Blood specimen drawn one month after last transfusion.
§ Blood specimen drawn three months after last transfusion.

Table 3 gives the results of titrations of the patient's serum. The initial titrations were carried out on serum obtained after she had received the second blood transfusion. At that time, her serum failed to show clumping by the saline agglutination, albumin-plasma conglutination, and antiglobulin methods. The fact that the antibody reacted only by the ficinated-cell method explains the failure of the technician to detect the offending antibody by the crossmatching tests, since the ficinated-cell method has never previously been used for compatibility tests. The second set of titrations was carried out with the patient's serum obtained after she had received the third blood transfusion, when the offending antibody was first detected in crossmatching tests. The third set of titrations was carried out on the patient's serum obtained approximately one month after her discharge from the hospital, and the results were similar to those of the second titration except that the titer values were higher, namely, 256 units. The titer of 2 units with group O rh cells, as previously noted, persisted. Seven months after the third titration another titration was carried out. At this time, although the titer values had fallen appreciably, the reaction for type rh cells persisted in a titer of one unit.

Tests were carried out on blood of members of the patient's family in order to investigate the hereditary transmission of her unusual agglutinogen Rh_2^{b}. Unfortunately, her husband could not be located, while her three sons all proved to have standard Rh-positive blood, that is, blood which has factor $\mathbf{Rh}_0$ and all the associated blood factors, $\mathbf{Rh}^A$, $\mathbf{Rh}^B$, and $\mathbf{Rh}^C$. The blood groups of her three adult sons (36 years, 35 years, and 30 years of age), were A_1B MN $\mathrm{Rh}_2\mathrm{Rh}_2$, A_1B N $\mathrm{Rh}_z\mathrm{Rh}_0$, and A_1B N $\mathrm{Rh}_1\mathrm{rh}$ respectively. While throwing no light on the heredity,[6] these results suggest that the original source of the patient's sensitization to the $\mathbf{Rh}^B$ blood factor might have been her pregnancies. These pregnancies probably acted as primers so that a latent sensitization was present when the patient was admitted to the hospital and the transfusions then stimulated the appearance (or possible reappearance) of the isoantibodies in the serum.[7]

Comment

From the onset, the findings in this case were puzzling and misleading and presented a complex clinical picture. The patient had portal cirrhosis, esophageal varices, and massive hemorrhages requiring surgical treatment and blood transfusion therapy. An enlarged spleen, enlarged liver, and absence of renal impairment or hemoglobinuria understandably caused the jaundice when it developed to be attributed to the primary disease rather than to the transfusion. The laboratory findings, too, were puzzling, in that an elaborate and acceptable pretransfusion crossmatching routine at first disclosed no serologic incompatibility between her blood, which was group B, Rh-positive, and that of blood of group B, Rh-positive donors. It was, therefore, reasonable to conclude that the post-transfusion reactions were simply pyrogenic.

There was no history of previous blood transfusions, yet, as a result of previous pregnancies, the patient was probably already isosensitized when admitted to the hospital. At the time of the first transfusion, the titer of the antibody was too low to be detected by any presently known crossmatching test but a chill and fever resulted. After repeated transfusions, the isoantibody became demonstrable and the incompatibility became detectable, so that further transfusions of Rh-positive blood were avoided. The offending new antibody was then identified, and to it was assigned the symbol anti-$\mathbf{Rh}^B$. We have observed that examples of anti-$\mathbf{Rh}^A$, anti-$\mathbf{Rh}^B$, and anti-$\mathbf{Rh}^C$, which are the only examples now available, all give the strongest reactions by the ficinated-cell and ficinated-cell antiglobulin methods. Yet these two methods have not been used previously for crossmatching tests. This case demonstrates the need to incorporate in the routine pretransfusion procedure sensitivity tests carried out with the patient's and donor's serum. This was suggested in 1954.[8] It further shows that, occasionally, bloods may appear to be compatible by the accepted routine procedures for crossmatching and that sensitivity tests may also fail to reveal the presence of an atypical antibody and, yet, transfusion may be followed by reaction. If agglutination is observed in sensitivity tests by the ficinated-cell or ficinated-cell antiglobulin methods, blood transfusion should be withheld until crossmatching tests have been carried out by the two new methods recommended in this paper. The commonly used ficinated-cell technique requires a considerable quantity of blood; therefore, the "short" method devised by one of us (A. S. W.) is recommended.

Summary

An Rh-positive patient sustained a hemolytic reaction after transfusions of seemingly compatible Rh-positive blood. In her serum, finally, an antibody was detected, closely simulating anti-$\mathbf{Rh}_0$ in specificity but differing in that it failed to react with her own red blood cells and those of certain other Rh-positive persons. Since the antibody also proved to be different from anti-$\mathbf{Rh}^A$, previously described by Wiener and Geiger, it has been assigned the symbol anti-$\mathbf{Rh}^B$. It is now known that in Rh-positive blood associated with the $\mathbf{Rh}_0$ factor there are multiple other blood factors, such as $\mathbf{Rh}^A$, $\mathbf{Rh}^B$, and $\mathbf{Rh}^C$. Physicians should watch for those rare Rh-positive patients whose blood lacks one or more of the associated factors, because such persons can be sensitized to the missing factor with resulting clinical complications, such as a hemolytic transfusion reaction or the birth of an erythroblastotic baby.

135 E. 74th St. (21) (Dr. Unger).

In this paper the recommendation of the Committee on Medicolegal Problems of the American Medical Association has been adopted to use regular type for symbols for agglutinogens and phenotypes, boldface type for symbols for blood factors and their corresponding antibodies, and italics for symbols for genes and genotypes.

SYNDROME OF MINIMAL CEREBRAL DAMAGE IN INFANCY

Hilda Knobloch, M.D.
and
Benjamin Pasamanick, M.D., Columbus, Ohio

Among the chronic diseases, the neuropsychiatric disabilities are probably the most costly in terms of loss of productivity, the need for provision of treatment and care, the chronicity, and the disruption of family life. Two major problems in this connection are the elucidation of etiological factors and the identification of deviation early in life so that plans for education and management can be made.

Some time ago we constructed the hypothesis of a "continuum of reproductive casualty" which has been investigated in a series of retrospective and anterospective epidemiologic studies. According to this hypothesis, there is a lethal component of cerebral damage which results in fetal and neonatal deaths and a sublethal component which gives rise to a series of clinical neuropsychiatric syndromes depending on the degree and location of the damage. We have found that these abnormalities range from the more obvious disabilities, such as cerebral palsy,[1] epilepsy,[2] and mental deficiency,[3] through the learning and behavioral difficulties, such as reading disabilities,[4] tics,[5] and the behavior disorders of childhood,[6] probably as a result of cerebral disorganization after minimal cerebral damage. The retrospective investigations have indicated that three prenatal and paranatal factors appear to be most highly associated with the components of this continuum, namely, prematurity, toxemia, and bleeding during pregnancy. In the retrospective study of children with behavior disorders, this association was found to be particularly high in the hyperactive, confused, and disorganized group. In this paper we propose to draw on one of the major anterospective studies, that of premature infants,[7] which supports the hypothesis by showing an increase in the brain damage in such infants, in order to discuss the clinical aspects of the syndrome of minimal cerebral damage in infancy and its prognostic importance in identifying infants who might later develop behavioral and learning difficulties.

If the hypothesis is correct, and those infants who have abnormal neurological findings early in life are the ones who present childhood behavior disorders, there is need for a more refined tool than the usual neurological examination of the infant and young child, since this is geared toward detecting gross defects, such as congenital anomalies of the central nervous system and advanced, expanding lesions of the brain. The lesser degrees of neurological abnormality are not readily defined by this procedure, and the minor abnormal neurological patterns are looked on merely as the "clumsiness" or "immaturity" that is described in all children. Because of the inextricable interrelationship of developmental maturational level and neurological functioning, a knowledge of the developmental patterns in infancy and early childhood defines the degree of so-called clumsiness to be expected at any given age and, furthermore, delineates what part of the body is involved and in what types of activities. Such knowledge also indicates whether the personal, social, and emotional response of the child is appropriate to his age, making it possible to explain deviant behavior by environmental factors; widely discordant responses would intensify the search for organic disease.

Examination of 500 premature and 492 full-term infants at 40 weeks of age indicated that there is a continuum of cerebral damage ranging from severe abnormalities, such as cerebral palsy and mental deficiency, to minimal damage. All degrees of involvement increased as the birth weight decreased. The number and severity of abnormal neurological and behavior patterns recorded varied directly with the severity of the clinical neurological diagnosis. The component items for a diagnosis of minimal cerebral damage in infancy are described. Findings of adaptive functioning at 40 weeks were found to be well correlated with maturity levels at 3 years of age and therefore have predictive value. Behavior problems in children have been ascribed to tension in their mothers, but the likelihood that an infant with difficulties produces tension in his mother needs serious consideration.

The syndrome of minimal cerebral damage as we define it is manifested by minor but clearly defined deviations from the normal neurological and behavioral developmental patterns, usually with more or less complete compensation by 15 to 18 months of age, as determined by the standard neurological examination. These developmental abnormal neurological signs persist well into the preschool period but require special techniques and a knowledge of maturity to elicit and interpret them. The syndrome is important in the early identification of expanding lesions of the brain, in following the progress of a child with a neurological abnormality, and in identifying those infants who, because of their cerebral disorganization, might be more apt to develop neuropsychiatric disorders later in childhood.

Director, Clinic of Child Development, the Children's Hospital, and Associate Professor of Pediatrics and Assistant Professor of Psychiatry, Ohio State University (Dr. Knobloch); and Director of Research, Columbus Psychiatric Institute and Hospital, and Professor of Psychiatry, Ohio State University (Dr. Pasamanick).

Method of Study

The present report is based on the examination of 500 premature and 492 full-term control infants who were evaluated as part of a study of premature infants conducted in Maryland since 1952. The details of the selection of the sample, the success of the follow-up study and completion of the examination, and the examination procedures have already been described.[7] These infants were all residents of Baltimore and were examined at an average age of 40 weeks. In premature infants, the chronological age was corrected for the estimated amount of prematurity. In considering the possibilities of bias, it is important to emphasize that the examiner, in the great majority of instances, had no knowledge at the time of the examination about whether the infant was premature or was a full-term control infant.

The following procedures were used in gathering information relative to the subject matter of this report: The details regarding the behavior in the first month of life, intercurrent illnesses, the occurrence of convulsive seizures, and the emotional behavior of the child were obtained from the mother at the time of the examination. For those infants examined in the office, someone other than the pediatrician, for the most part one nurse on the study staff, interviewed the mother. When the infant was examined at home or elsewhere, the pediatrician obtained the history after the examination was completed and recorded. An estimate of the mother's behavior in terms of self-assurance and tension was made by either the nurse or the physician at the time the history was taken. The neuropsychiatric developmental examination of Gesell and Amatruda [8] and a physical examination were done by the pediatrician, and, among other things, a diagnosis of neurological status and a prediction of intellectual potential were made.

The neurological status is an estimate of the integrity of the central nervous system as this is manifested by the absence or presence of impairment in neuromotor functioning and deviations in muscle tonus and control. It is expressed in terminology, appropriate to the field of infant neurology, which indicates the extent of departure from normal and comprises five categories. Those infants who are called normal are without abnormal neurological findings, while those in the "possible minimal damage" category have deviations from normal patterning so minor that they are considered to be of no clinical significance and, for summary purposes, this group is added to the normal group. The syndrome of minimal damage has already been defined. Another group, "possible cerebral palsy," includes infants who have signs and symptoms which would warrant a diagnosis of cerebral palsy had they been observed in an older child. However, although clinical experience with the examination technique indicates that most infants with this degree of abnormality at 40 weeks of age eventually compensate completely and have no detectable neurological residuals, cerebral palsy can not be ruled out definitively. The final group, with overt abnormality, shows gross deviations from normal neurological patterning of sufficient degree to raise serious questions about future development. These are infants who would be expected to show abnormal neurological patterns detectable by a standard neurological examination in the later preschool or early school period.

Findings

The distribution of the neurological diagnoses in the premature and the full-term control groups is shown in table 1; this table indicates that, as the birth weight decreases, the amount of damage increases. Of those infants whose birth weight was 1,500 Gm. (3½ lb.) or less, 26.3% were in the possible cerebral palsy or overt neurological abnormality groups, the comparable figures for the larger premature infants and the full-term control infants being 7.2 and 1.6% respectively. When data in the premature group are adjusted for the birth weight distribution of the infants, the incidence of the serious neurological abnormalities in the total premature group is 8.2%. In the minimal damage group were 22.8% of the very small premature infants, 16.0% of the larger premature infants, and 10.0% of the full-term control infants. Again, the rates are significantly higher in the premature infant

TABLE 1.—*Neurological Status of Premature and Full-term Control Infants at Examination at Forty Weeks of Age, Baltimore, 1952-1953*

Weight Group, Gm.	No. of Infants	Normal, %	Possible Minimal Damage, %	Minimal Damage, %	Possible Cerebral Palsy, %	Overt Abnormality, %
Premature						
1,500 or less...	57	29.9	21.0	22.8	14.0	12.3
1,501-2,500	443	63.6	13.1	16.0	5.6	1.6
Subtotal, adjusted for weight distribution ...	500	62.0	13.5	16.3	6.1	2.1
Control, 2,501 or more	492	78.0	10.4	10.0	1.0	0.6
Total	992	68.9	12.2	13.4	3.8	1.7

Analysis of the behavior patterns in the first month of life and up to the time of the examination, about which information was obtained on the basis of the history, indicates that, in general, as the neurological abnormality increases the incidence of an abnormal pattern increases. In the first month of life there are significant differences among the neurological groups for difficulty in sucking, hypotonicity, and hypertonicity. Up to the time of the examination there are significant differences in the incidence of twitching and convulsions, in the number with feeding problems, in the percentage of infants described as usually cranky and unwilling to play alone, and in the number afraid of strange things and situations. Also, the percentage of mothers described as tense and uncertain increases as the degree of neurological abnormality increases.

In addition to this general analysis of historical material, a detailed study was made of 46 individual neurological patterns in order to see the actual relationship between the amount of abnormality recorded and the clinical neurological diagnosis made, thus defining the diagnostic criteria more precisely. The neurological patterns were rated as 0, or normal, and 1, 2, and 3 +, representing varying degrees of abnormality. For each of the neurological categories the average score of all of the cases for the entire 46 patterns was obtained. The results shown in table 2 indicate that the mean score increases significantly as the severity of the estimate of neurological status increases. The mean score for the normal group is 3.9, for the possible minimal damage group 11.1, for the minimal damage group 20.9, for the possible cerebral palsy group 24.8, and for the overt abnormality group 27.7.

Further analysis of the individual items was done to determine the correlation of a given pattern with the remainder of the patterns and to rank them as to their importance in distinguishing between the neurological diagnostic categories. Only 16 of the 46 items do not differentiate significantly between the normal and the minimal cerebral damage groups. In most cases, either the pattern was one indicative of more serious abnormality, such as persistence of a tonic neck reflex or the presence of athetosis, or the total number of infants with that behavior was too small. Only 4 of these 16 patterns do not differentiate at all over the five diagnostic categories, primarily because the total number of infants with the pattern was too small. The items which have the highest correlations with the remainder are those in areas which one might expect at 40 weeks of age: difficulty in the use of the hands and changes in reflexes or muscle tone. (The complete listing and distribution of the individual behavior patterns among the neurological diagnostic categories is available from the authors, but the table is too detailed to be given here.)

TABLE 2.—*Mean Score on Individual Neurological Patterns According to Diagnosis at Forty Weeks of Age, Baltimore, 1952-1953*

Neurological Status	No. of Cases	Mean Score	Standard Deviation
Normal	680	3.9	1.4
Possible minimal damage	121	11.1	5.8
Minimal damage	137	20.9	7.5
Possible cerebral palsy	37	24.8	8.4
Overt abnormality	17	27.7	11.5

Comment

Of utmost importance to the interpretation of the meaning of these findings is the relationship of the behavior in infancy to that found later in life. Contrary to most previous reports,[9] our findings indicate that, when the developmental examination of Gesell and Amatruda is used as a clinical neurological tool by a physician trained in the techniques, it is possible to predict the later development.[10] In contrast to reports in the literature of correlations ranging from 0.2 down to small negative correlations, when the maturity levels of approximately 300 children examined at 3 years of age were correlated with the findings at 40 weeks, a correlation of 0.75 was found for those infants called abnormal at 40 weeks of age, while a correlation of 0.5 was found in the total group.

As would be predicted by the definitions of the neurological status categories, there is a shift toward a diagnosis of less severe involvement with increasing age. The ultimate answer to the major question of the prognostic value of the syndrome of minimal cerebral damage awaits further follow-up examination of these infants and cannot be given at the present time. When these children enter school it will be possible to determine if those infants given the diagnosis of minimal cerebral damage are the ones who present behavioral and learning disorders.

In regard to this point it is interesting to comment on the judgment made of the mothers. In this group of infants the tension of the mothers increases as the severity of the neurological diagnosis increases. Since behavior problems in children are often attributed to tension in their mothers, the present data raise the question of whether some serious consideration should be given to the other side of the coin, namely, that the infant with difficulties produces the tension in his mother.

Clinicians have long been aware that evidence of early neurological abnormalities can be obtained by history. These clinical hunches are supported by the present findings which highlight some of the signs to be looked for. Even if a detailed developmental examination cannot be done by every physician, a careful and detailed history can be taken. Information about the early behavioral and developmental findings might well lead to the prompter identification of those infants who will later develop disorders, should the hypothesis of the role of minimal cerebral damage in producing them be borne out with time. This history, it should be obvious from the nature of the questions asked, must be taken by the physician, and this task cannot be relegated to the social worker or the psychologist.

The objectivity of the method of examination is indicated by the correlation of the clinical neurological category with the increase in number of abnormalities described. Although a great deal about the natural development of neurological patterns was learned in follow-up study of the 300 infants examined at 40 weeks and at 3 years, further refinement of the procedure is indicated so that clinical acumen can be increased. If a scoring system can be developed the scores on individual items will need to be weighted so that an item which clearly differentiates, such as athetosis, is not given the same weight as an item such as fisted hands. The system will then need to be validated with another group of infants and the findings of more than one examiner compared in a systematic fashion. We are in the process of doing this at

It is clear, however, that a score can never replace clinical judgment. One of the important factors in this judgment is the early behavioral and developmental history. Greater emphasis will need to be placed on this when an attempt is made to evaluate the nature of a neuropsychiatric disability at any age.

Summary

Examination by means of the neuropsychiatric developmental examination of Gesell and Amatruda of 500 premature and 492 full-term control infants

at 40 weeks of age indicates that the amount of neurological damage increases as the birth weight of the infant decreases. Reports of behavior in the first month and up to the time of the examination showed a correlation between the degree of abnormality diagnosed at the examination and certain historical material obtained from the mother. Analysis of 46 individual neurological patterns demonstrated a correlation between the amount of abnormality recorded and the clinical diagnosis of the neurological status and delineated those patterns most useful in discriminating between normal and damaged infants. Particular emphasis is placed on those symptoms which comprise the syndrome of minimal cerebral damage, which was found in 100 infants. The findings emphasize the responsibility of the physician in taking a careful history of early behavior and development in order to evaluate the nature of a neuropsychiatric disability at any age.

FULMINATING MENINGOCOCCEMIA (WATERHOUSE-FRIDERICHSEN SYNDROME)

REPORT OF TWO PATIENTS SUCCESSFULLY TREATED WITH CHEMOTHERAPY, VASOPRESSORS, AND ADRENAL STEROIDS

David M. Berkson, M.D., Lawrence Perlman, M.D.
and
Albert J. Miller, M.D., Chicago

Weight of clinical evidence at the present time favors the combined use of appropriate chemotherapy, vasopressors, and intravenously given adrenal steroids in all cases of fulminating meningococcemia. Reports appear to indicate that there is increased peripheral utilization of steroids in these patients. Review of the literature reveals no consistent picture so far as adrenal hemorrhage is concerned. Combined use of sulfisoxazole or sulfadiazine and intravenously given arterenol and hydrocortisone represents the therapy of choice.

Fulminating meningococcemia (Waterhouse-Friderichsen syndrome) is an overwhelming infection with severe prostration, purpuric or ecchymotic lesions of the skin, and marked hypotension. It is a grave illness carrying a high mortality. The purpose of this paper is to report the cases of two adult patients with fulminating meningococcemia who were treated successfully and to review briefly certain aspects of the therapeutic approach to this disease.

Report of Cases

CASE 1.—A 59-year-old woman was admitted to the Michael Reese Hospital in a semicomatose state on Jan. 31, 1958, at 12:45 a. m. She had returned from India one week prior to admission,

---

From the Department of Medicine, Michael Reese Hospital.

apparently in good health. Three days after her return she noted malaise and a vague general discomfort. The next day she developed headache, chills, and fever with temperature of 103.2 F (39.6 C). She was seen by a physician, who prescribed aspirin. The fever persisted throughout the next day, and then the temperature dropped to subnormal levels. Simultaneously she began to lose control of her faculties. Emesis occurred, and a rash appeared over her entire body. She was seen at home by one of us and was noted to be in shock, unresponsive, and gravely ill. Cortisone, 50 mg., was administered intramuscularly, and she was sent to the hospital. Examination on admission revealed the temperature to be 96.6 F (35.9 C) rectally. The blood pressure was 80/0 mm. Hg and the pulse rate 80 beats per minute. The skin was cold and moist and covered with a purpuric and ecchymotic rash. The neck was rigid. The lung fields were clear. Heart examination gave negative findings except for a soft, grade-1, systolic murmur at the apex. Abdominal examination gave negative findings. Painful stimulation elicited only slight withdrawal response. No focal neurological signs were evident.

Lumbar puncture on admission revealed a cloudy spinal fluid with many polymorphonuclear leukocytes and gram-negative diplococci which were typical of meningococci. The spinal fluid glucose level was 6 mg.%. The spinal fluid protein level was 651 mg.% and the chloride level 585 mg.%. The hemoglobin level was 13.1 Gm.% and the white blood cell count 12,150 per cubic millimeter with a marked shift to the left. The blood urea nitrogen level was 54 mg.%, creatinine level 3.4 mg.%, serum chloride level 90 mEq. per liter, serum sodium level 132 mEq. per liter, serum potassium level 3.1 mEq. per liter, and carbon dioxide–combining power 23.4 mEq. per liter. The prothrombin time was 19.2 seconds. A platelet count showed 319,000 per cubic millimeter. The bleeding time (Duke method) was two minutes; the clotting time (Lee-White method) was 16 minutes. A chest roentgenogram was interpreted as being within normal limits. An electrocardiogram showed nonspecific T-wave flattening in all the limb and precordial leads.

Antimicrobial therapy with sulfisoxazole (Gantrisin), penicillin, and chloramphenicol was begun. Intravenously given fluids containing hydrocortisone and arterenol were administered, the latter in a concentration of one ampul (4 mg.) per 1,000 cc. of fluid, at a rate of 40 to 60 drops per minute. The systolic blood pressure was maintained between 120 and 130 mm. Hg. In the first 24 hours she received 8 Gm. of sulfisoxazole intramuscularly, 0.5 Gm. of chloramphenicol intravenously and 2 Gm. intramuscularly, and 2,000,000 units of procaine penicillin G intramuscularly. At the end of the first 24 hours of hospitalization she was more responsive and complained of headache. The blood sulfonamide level was 16 mg.% and was maintained between 10 and 15 mg.% during the remainder of sulfisoxazole therapy.

Arterenol therapy was discontinued on Feb. 3, the blood pressure remaining stable thereafter. The urinary output was adequate, being over 3,000 cc. per 24 hours, and the blood urea nitrogen level decreased to 23 mg.%. The patient became alert, responsive, and well oriented. There were no abnormal neurological findings. On the same day, chloramphenicol therapy was discontinued and the patient was maintained on a regimen of sulfisoxazole given intravenously and penicillin and hydrocortisone given intramuscularly. Sulfisoxazole was given orally in doses of 6 Gm. per day from Feb. 5 to Feb. 22, when this therapy was discontinued. Methylprednisolone (Medrol) therapy was begun in doses of 40 mg. per day on Feb. 5, and the dosage of hydrocortisone was gradually decreased. The remainder of her hospital course was uneventful except for a Monilia infection of the mouth which responded to treatment with nystatin. The dosage of methylprednisolone was gradually decreased to 6 mg. per day at the time of discharge. The skin lesions, many of which had progressed to necrosis, gradually healed. The patient was discharged on March 1, 1958, at which time she had generalized weakness and numbness over the ulnar nerve distribution of the right hand with a diminution in pain perception in this area. The urinary output of 17-ketosteroids was 3.8 mg. per 24 hours.

Case 2.—A 40-year-old man was admitted to the Michael Reese Hospital on June 1, 1954. He had been brought back to Chicago from a fishing trip because of shaking chills, cough, fever, generalized aching, and malaise of 24 hours' duration. On admission he appeared acutely ill, with a temperature of 105.4 F (40.8 C), blood pressure 100/70 mm. Hg, and respiration rate 40 per minute. The skin was flushed, and numerous petechiae were present over the back, arms, and abdomen. A few petechiae were also noted on the conjunctivae and soft palate. There was slight dulness with bronchial breathing and diffuse crepitant rales over the right upper lung field. Neither nuchal rigidity nor focal neurological signs were evident. Shortly after admission the blood pressure dropped to 70/40 mm. Hg.

Lumbar puncture was performed on the day of admission and revealed a pressure of 160 mm. H_2O, Pandy's test reaction 2+, and 13 polymorphonuclear leukocytes per cubic millimeter. The spinal fluid glucose level was 55 mg.%, protein level 38 mg.%, and chloride level 765 mg.%. A second lumbar puncture on June 2 revealed a cloudy fluid and a white blood cell count of 2,380 cells per cubic millimeter, with 92% polymorphonuclear cells. Pandy's test reaction was 4+, the glucose level 97 mg.%, protein level 144 mg.%, and chloride level 709 mg.%. The hemoglobin level was 15.7 Gm.% and the white blood cell count 42,600 per cubic millimeter. The blood urea nitrogen level was 20 mg.%, creatinine level 1.3 mg.%, blood sugar level 191 mg.%, chloride level 117 mEq. per liter, sodium level 141.9 mEq. per liter, potassium level 3.2 mEq. per liter, and carbon dioxide–combining power 17.9 mEq. per liter. There were 300,000 platelets per cubic millimeter. The prothrombin time was 17 seconds, bleeding time (Duke method) two minutes, and clotting time (Lee-White method) 12.5 minutes. Cultures of the blood and of the nasopharynx grew meningococci, type 2. Cultures of the spinal fluid and of the urine were sterile. Viral and rickettsial agglutinations gave negative results. A chest x-ray revealed a left upper lobe pneumonitis and pleural or pulmonary fibrosis in the right upper lobe compatible with old tuberculosis infection. An electrocardiogram showed first-degree atrioventricular block.

On admission the patient was given 1,200,000 units of procaine penicillin G intramuscularly, 5 Gm. of sulfadiazine intravenously, 200 mg. of cortisone intramuscularly, 100 mg. of hydrocortisone intravenously, and oxygen. In addition, arterenol in a concentration of six ampuls (24 mg.) per 1,000 cc. of fluid was administered intravenously at a rate of 20 to 30 drops per minute to maintain the systolic blood pressure between 105 and 110 mm. Hg. The next day the temperature fell to 100 F (37.7 C). On this day auricular fibrillation developed and the patient was rapidly digitalized. Two days later, on June 4, the rhythm reverted to a sinus mechanism. Transient nuchal rigidity and microscopic hematuria were noted at this time. Because of the hematuria, sulfadiazine therapy was discontinued and tetracycline, in a dosage of 400 mg. daily given intramuscularly, was substituted. Because of the history of tuberculosis, the abnormal chest x-ray, and the administration of corticosteroids, antituberculosis therapy with isoniazid, 300 mg. per day, and streptomycin, 1 Gm. given intramuscularly twice weekly, was instituted on June 4. Arterenol therapy was discontinued on June 6, after which the systolic blood pressure remained at a level of 90 to 100 mm. Hg. The dosage of cortisone was gradually decreased from 200 mg. per day, and on June 8 this therapy was discontinued. The further hospital course was uneventful, and the patient was discharged on June 15, 1954.

Comment

In a review of 16 cases, including autopsies, of patients with fulminat[illegible] Ferguson and Chapman[1] [illegible]ad no gross evidence of adrenal hemorrhage. Three other patients showed only slight to moderate adrenal hemorrhage. They concluded that there are no clinical signs by which one can distinguish between patients with and those without adrenal hemorrhage. They observed no correlation between the extent of adrenal damage and the degree of clinical vascular collapse. This inability to determine on clinical grounds whether adrenal hemorrhage has occurred was also noted by Daniels.[2] In a review of 300 cases, with autopsy, of meningococcemia, there were five patients with hemorrhagic adrenals who did not exhibit the clinical picture of fulminating meningococcemia. There were four patients with the classic form of this disease without adrenal hemorrhage.

In 1944 Rich[3] reported that acute infections with the clinical picture of circulatory collapse may produce a necrosis of isolated cells of the adrenal cortex with the transformation of solid cords in the zona fasciculata to tubular structures. He observed these changes in meningococcic, pneumococcic, streptococcic, and diphtheritic infections in patients with the clinical picture of vascular collapse. He stated that most adults with overwhelming meningococcemia, in contrast to children, failed to show a significant degree of adrenal hemorrhage.

Nelson and Goldstein[4] utilized the microscopic findings of Rich to explain those cases of clinical fulminating meningococcemia in which gross adrenal hemorrhage is not seen at autopsy. They postulated that with the same clinical picture the pathological changes in the adrenal glands may vary from microscopic changes in the cortex to complete destruction by hemorrhage.

There remains some difference of opinion regarding therapy in fulminating meningococcemia. The efficacy of antimicrobials is unquestioned. The excellent results achieved with sulfisoxazole[5] and sulfadiazine[6] in the treatment of meningococcic meningitis make these the drugs of choice. This unanimity of opinion is lacking when adjunct therapy is considered. In 1951, Nelson and Goldstein[4] reported two patients successfully treated with cortisone. Tobin,[7] in a report of 63 cases of meningococcic meningitis, encountered nine patients with fulminating meningococcemia. He felt that the effects of cortisone were not spectacular and that, while continuous intravenous infusion of arterenol usually raised the blood pressure, it did not necessarily sustain it. Uhl,[8] on the other hand, reported recovery in a patient with fulminating meningococcemia in whom arterenol was used to treat shock after adrenal cortical extract had failed. Cassidy[9] reported the cases of 17 patients with meningococcic infection, 10 of whom had meningococcemia. In this series, hydrocortisone was administered intravenously in a dosage of 300 mg. per 24 hours, and no case of peripheral vascular collapse developed. Kanter and co-workers[10] noted a mortality of 50% in 10 patients with acute meningococcemia and vascular collapse. They used arterenol, hydrocortisone given intravenously, and cortisone given intramuscularly. Koch and Carson,[11] in a study of a group of infants and children, reported universally poor results, with no difference in the outcome in patients with fulminating meningococcemia between those treated with corticosteroids and vasopressors as compared with those treated before these agents were available.

Kass and Finland[12] determined the circulating blood hydroxycorticosteroid levels in 12 patients with collapse attributable to sepsis of varying etiology. These levels were usually above the normal range, and in none were they below normal. They observed three cases of fulminating meningococcemia in which treatment with sulfonamides and arterenol alone was successful and concluded that there is little rationale for the use of adrenal steroids.

Spink[13] confirmed the work of Kass and Finland by finding normal or increased blood levels of hydrocortisone in patients with severe infection. He also found the plasma half-life of administered hydrocortisone to be significantly less in patients with vascular collapse who eventually recovered than in normal control subjects. The half-life was prolonged in those who did not survive. These reports may be interpreted to indicate that in these conditions there is an increase in the peripheral utilization of steroids until a point is reached in the severity of the illness beyond which the peripheral response fails. Previous studies from this institution have shown that adrenal cortical hormones condition the vascular response to arterenol under certain experimental conditions.[14]

Although the reports are contradictory, we believe the weight of evidence at the present time favors the combined use of appropriate chemotherapy, vasopressors, and intravenously given adrenal steroids in all cases of fulminating meningococcemia. We base this conclusion on the continuing reports of probable clinical efficacy, the suggestion of greater peripheral utilization of corticosteroids in severe stress states, and the experimental work indicating the importance of adrenal hormones in conditioning small blood vessels to vasoconstrictor agents and in preventing capillary disruption.

Summary

Two adult patients were successfully treated for fulminating meningococcemia (Waterhouse-Friderichsen syndrome). The combined use of sulfisoxazole or sulfadiazine and intravenously given arterenol and hydrocortisone represents the therapy of choice.

SEXUAL POTENCY IN AGING MALES

I. FREQUENCY OF COITUS AMONG CLINIC PATIENTS

Alex L. Finkle, M.D., Thomas G. Moyers, A.B., Mark I. Tobenkin, M.D.
and
Sara J. Karg, M.A., San Francisco

Questions about sexual activity were interspersed among other clinical questions in the examination of 101 men between 55 and 86 years of age. All were ambulant patients whose presenting complaints did not per se constitute impediments to sexual activity. Of 51 patients 69 years or less of age, 33 (65%) were potent in the sense of having copulated at least once in the previous year. Of 50 men over 70 years of age, 17 (34%) were potent. There was a general decline with age, but individual differences were marked, and two of the five men who were over 80 years old stated that they were still active, with 10 as the average number of copulations per year. These results are of fundamental importance in assessing the functional results of various types of prostatectomy.

No adequate survey of sexual activity among aging men is available. Therefore, any surmise about the impairment or decline of sexual function after prostatic surgery or comparable insult to the genitourinary apparatus is necessarily ambiguous. Manifestly, a base line or standard for comparison of sexual activity in men for the decades above 50 years of age is desirable. The present survey represents an attempt to acquire such information.

Since physicians and patients often misinterpret the term "sexual potency,"[1] consensus as to definition is desirable. For purposes of the present report, sexual potency is regarded as the ability to activate psychic ("emotional") desire for sexual intercourse into penile erection adequate for coitus and to achieve gratification (usually ejaculation) during the sexual act. Implicit in this definition is that more than penile erection per se is involved. Moreover, incomplete penile erection with postcoital gratification of wife and/or husband does satisfy the conditions of this definition. Frequency of sexual activity is not important; participation only once annually must be regarded as evidence of potency.

Little information can be found in the literature regarding sexual potency or frequency of coitus in older men. Kinsey and co-workers[2] made brief reference to "old age and impotence," but they attempted no exhaustive survey of this group of men. Dahlen and Goodwin[1a] touched on the subject of loss of potency after open perineal prostatic biopsy; however, some phases of their report have been challenged as equivocal.[3] Young and Davis[4] cited, in general terms, data about sexual performance in patients subjected to perineal prostatectomy. Loss of potency postoperatively was regarded as infrequent, since many of their patients were reportedly in sexual decline before operation. However, present-day opinions—although unverified—regard perineal prostatectomy as the most likely of all such surgical approaches to result in sexual impotency.[5] It is difficult to believe in the objectivity of the data in some reports; others, which fail to cite series of cases, are likewise equivocal.[6]

Neurophysiological integrity was assumed in the present investigation, since it was not our purpose to study this obvious basis for impotency.[7] Our essential interest, admittedly not exploited exhaustively, pertained to the psychophysiological, sociological (mores of the group, occupational stratum, and availability of partner at given time, place, and circumstance), and personal perspectives of the patients. We did not study any specific group of patients, as did Rubin and Babbott.[8]

Material and Methods

Patients were interviewed in the medical and surgical outpatient clinics of the University of California School of Medicine as they waited to see the doctor who would evaluate the particular problems for which they sought advice. In the beginning of our study the "potency survey" was done by fourth-year medical students during the course of taking a full clinical history of each patient. This resulted in many cursory and indifferent reports. The data obtained by the medical students were therefore discarded. This experience also caused us to devise a questionnaire more specific than that originally employed; this questionnaire was used in all subsequent interviews with unselected patients, providing the information for the present report. Questions about sexual performance were interposed among the usual clinical inquiries rather than kept separate, which might have disturbed the patient.

From the Division of Urology, University of California School of Medicine.

All patients were in the age range between 55 and 86 years. In no instance was a genitourinary problem the primary cause for which the patient had solicited medical care, although history of such associated problems was occasionally elicited. No patient was included who presented language or other barriers to reliable replies. Sexual intercourse within the preceding year was considered the minimal requirement for inclusion in the "sexually active" group. It was believed that the answers given by patients were grossly reliable. In the age groups evaluated, and under the circumstances of the interview, little if any motivation existed for falsifying the reply.

Results

One hundred one randomly encountered patients were interviewed for and included in this study. As shown in tables 1 and 2 correlations were made between indulgence in or abstinence from sexual intercourse and such factors as age and occupational and marital status.

No essential differences were discernible between men reached through the medical and surgical outpatient clinics, although most patients (66) were encountered in the medical clinic. Therefore, source of the patient was not specified in our final analysis. In no instance was the presenting complaint sufficiently disabling to cause impediment, per se, to sexual activity. All patients were ambulant.

TABLE 2.—*Sexually Inactive Men*

Of 101 patients about twice as many of the subjects interviewed between the ages of 55 and 69 years were sexually active (33) as were inactive (18). Conversely, the men over 70 years of age were more often inactive (33) than potent (17).

Of the sexually inactive men about one-third were single (never married), a similar number were either widowed or divorced, and one-third were married. Of the entire group 87% gave "no desire" as their main reason for quiescence. Some were included within the category of "no desire" even if they offered a minor or accessory "reason" such as fear of aggravating an inguinal hernia. Some men had penile erections but no desire for coitus; some had no penile erections and also "no desire for sex." We made no attempt to differentiate which situation was primary, i. e., "no desire" or "no penile erection." As cause for sexual inactivity among the remaining 13% (seven patients) who did not copulate, three specified absence of penile erection, three inability to find a coital partner, and one his wife's refusal. It so happened that all single men over 70 years of age were sexually inactive at the time of the interview; some had never had sexual intercourse. Of nine single men under 70 years of age, four were sexually active.

Table 3 summarizes the percentages of sexually active men within different age groups and frequency of coitus within those age ranges. Within our survey occupational status had no apparent bearing on sexual activity or decline. Both laborers and skilled workers, encountered in similar numbers, participated as frequently or were sexually dormant to a comparable degree. Although few "white collar workers" and no professional persons are included in this survey, these data do offer a certain uniformity as to vocational background.

Results to be reported later will include larger proportions of clerical and professional personnel.

Excluded from the present report, although interviewed during our random survey in the medical and surgical outpatient clinics, were eight patients who had had prostatectomy. Five of these were potent, irrespective of age or years elapsed since prostatectomy. The other three patients had not engaged in sexual activity prior to the surgical operation. It was interesting that, despite removal of the prostate as a historical event for a given patient, the operation had no noticeable effect on sexual performance when no current threat was directed against his present sexual potency.

Comment

Age is an indisputable factor relating to decline in the frequency of sexual intercourse. It is not an invariable agent, however, as emphasized by Stokes,[9] since some elderly men averred remarkable sexual aggressiveness. In general, men older than 65 years demonstrate progressively lowered interest and participation in sexual activity.

Table 3.—*Sexual Activity Related to Advancing Age*

Age, Yr.	No. of Patients	Sexually Active, %*	Intercourse, No. of Times per Year†
55-59	16	69	29
60-64	16	63	28
65-69	19	63	12
70-74	28	39	25
75-79	17	24	11
80+	5	40	10
Total	101	49.5	

* These percentages err toward conservatism in excluding men who desired coitus but had no partner.

† Average for group.

It is often presumed that men engaged in "physical" occupations indulge in sexual activity more frequently than those in "sedentary" or "clerical" occupations. Our data do not support this presumption; individual variations are so great as to preclude generalizations.

Collections and analyses of data, such as those by Kinsey and co-workers,[2] are sorely needed. Pure objectivity on the part of subject and interviewer may not be realized but should be pursued. Errors on the part of the patient as well as the interviewer are inevitable. For example, as Dahlen and Goodwin[1a] noted in their report, "it was not always possible postoperatively to be certain of the patient's memory of his potency prior to operation."

This survey was considered too limited for drawing conclusions concerning national origin, race, religion, or financial status. Such factors as the leisure time available to retired people and the mores of a given community were not evaluated at this time, although these doubtlessly affect a person's sexual interests.[10] By the same token, we did not analyze any patterns of sexual frequency established in younger years in relation to the patient's sexual interest and behavior in later life. In speculative terms, however, it would seem unlikely that a man of conservative sexual interests in his early adult life would suddenly blossom forth as a satyr in his older years. In similar terms, we did not pursue the matter of whether the wife's company all day would dull sexual ardor in older men retired from active employment. Finally, it appeared that moral self-determination is flexible, i. e., human frailty is such that many men transgress the bounds of propriety and become sexually potent with extramarital opportunities while remaining inert in their marital environment.

Summary

The sexual activity of 101 men over 55 years of age was recorded by personal interview. Within our definition of sexual potency about twice as many men up to 70 years of age were sexually active as those over that age. Among sexually potent men marital status was more influential than occupation or age in encouraging continued sexual activity.

PILONIDAL SINUS CARCINOMA

Mandel Weinstein, M.D., Morton Roberts, M.D.
and
Brian Reynolds, M.D., Jackson Heights, N. Y.

More thorough gross and microscopic study of pilonidal sinus specimens may reveal a higher incidence of carcinoma than has been indicated in the medical literature. Gross symptoms suggesting malignant change include bleeding, ulceration, and overgrowth. These are especially noteworthy when occurring in sinuses present for many years. Surgery consists of wide and deep excision. Carcinoma in a pilonidal sinus is most commonly of the squamous cell type, slow in growth and not prone to metastasize.

Carcinoma complicating pilonidal sinus is rare. There have been recorded in the surgical literature only 12 cases, 1 of which was published by us in 1957.[1] Within a month after this publication, a second patient with pilonidal carcinoma appeared, an unusual occurrence for one surgical practice. The present article will afford an opportunity not only to present this second case but also to report a follow-up study of the first patient four years after the operation.

Up to the present time the literature documents only 12 cases of pilonidal sinus with superimposed carcinoma. Although chronic irritation and inflammation have always been mentioned and accepted as causes for carcinoma, malignancy in chronic draining sinuses is not considered too common.[2] As far back as 1828, Marjolin[3] reported carcinoma in skin ulcers. In 1833 Hawkins[4] noted carcinomas forming in the scars of fistulas. McAnally and Dockerty[5] of the Mayo Clinic added several cases to the literature in 1949 in a study on the development of malignancy in draining sinuses. However, their patients had the chronic suppurating sinuses of osteomyelitis, empyema, and anal fistula.

A malignant neoplasm in a pilonidal sinus is slow growing and therefore has a good chance of being cured by early radical surgery. Metastases occur late, and the location in the sacrococcygeal region permits a wide excision of the growth. The skin and subcutaneous tissue should be excised at least 2 in. from any recognizable tumor tissue if one hopes to eradicate the disease completely. After this the dissection must advance into the depth of the wound so that the specimen is removed en masse from the fascia of the gluteal muscles laterally and the periosteum of the sacrum and coccyx medially. Hemostasis is easily controlled with the coagulating current, and the wound is packed in the wide open position. In about a month the wound is filled with granulation tissue and is ready for skin grafting.

Our first case of pilonidal sinus carcinoma occurred in a 43-year-old man with a 21-year history of a periodically draining mass in the sacrococcygeal region. At operation on May 27, 1955, with the patient under spinal anesthesia, a radical excision was performed with complete removal of the tumor, sinuses, and a generous surrounding area of normal tissue. The wound was left open and packed with gauze. The patient was readmitted for skin grafting on June 30, 1955. The skin defect was completely covered, the patient remaining in the hospital for eight days, after which he was discharged with a well-healed wound. Pathological diagnosis was squamous cell (epidermoid) carcinoma arising in a pilonidal sinus. This man has been given frequent follow-up examinations and is alive and well without any evidence of recurrent disease for a period of four years.

Matt,[6] in September, 1958, reported the 12th case of pilonidal carcinoma. This was in an 18-year-old male with a one-month history of sanguinopurulent discharge over the region of the sacrum and coccyx. The lesion was totally excised and subsequently diagnosed as a mixed basal and squamous cell carcinoma of a pilonidal sinus tract and perianal skin. A satisfactory six-year follow-up period was reported. Our second case of a pilonidal sinus carcinoma is herewith reported, making the 13th case to be recorded in the literature.

Report of a Case

A 51-year-old man was first examined on July 30, 1957. He gave a history of having had a discharging sinus over the lower part of the spine for 15 years. This became infected at least two or three times a year and drained spontaneously. He first noticed bleeding in July, 1957. His general health had always been good with no serious medical or surgical illnesses. The family history was noncontributory.

Physical examination revealed a healthy, obese man weighing 186 lb. (84.4 kg.). His blood pressure was 140 mm. Hg systolic and 90 mm. Hg diastolic. The rest of the examination gave essentially negative results except for the local findings. In the sacrococcygeal region, 4 in. above the anus and extending to the right of the midline, there was an area 6 cm. in diameter with seven or eight discharging sinuses and cicatrized tracts. The lymph nodes in the right groin were slightly enlarged and firm but mobile. There were no enlarged nodes in the axillae or left groin.

On Aug. 7, 1957, a radical extirpation of the lesion was performed. The entire mass was widely excised down to the gluteal fascia and the periosteum of the sacrum and coccyx. The wound was left open and packed with gauze.

The surgical pathological report showed the specimen to consist of a roughly oval mass of skin and subcutaneous fat, measuring 130 mm. in one diameter and 115 mm. in the other and averaging approximately 40 mm. in thickness. Arising from the center was a raised, granular, somewhat papillary mass which protruded about 15 mm. above the remainder of the skin surface. The mass varied in color from a light gray to a dirty brown and had ulcerated areas. The cut surface was light gray and friable. Microscopic examination showed living stratified squamous epithelium, most of which had been replaced by atypical squamous cells. These extended irregularly into the subcutaneous tissue. Pearl formation was prominent; focal lymphocytic and plasmacytic infiltration were also present. The pathological diagnosis was squamous cell (epidermoid) carcinoma.

He remained in the hospital four days, and on Sept. 20, 1957, five weeks after discharge, he returned for a skin grafting operation. He was discharged for the second time on Sept. 26, 1957, with a complete "take" of the graft. He was reported doing well until Oct. 4, 1957, eight days after his second hospital discharge, when he suddenly died at home. Death was clinically diagnosed as due to a pulmonary embolus, even though no autopsy was performed.

Comment

A review of the pathology of all of the 13 cases of pilonidal sinus malignancy reported thus far reveals the presence of variegated forms of carcinoma. A summary of the reported cases is given in the table.

Almost all the patients had symptoms which should have been considered possibly serious if they occurred in old pilonidal sinus wounds: (1) long-standing and persistent sinuses with drainage, (2) sudden, rapid growth, (3) overgrowth, above the skin level, (4) friability, (5) ulceration, (6) hemorrhage into the tissues, and (7) external bleeding. The most common observation related by the patients was bleeding that occurred in sinuses present for many years.

Summary

Malignant neoplasms are found implanted in pilonidal sinuses infrequently. This is not consistent with the accepted theories as to the relation of cancer to chronic inflammation. In the literature in which the type of carcinoma was mentioned, squamous cell (epidermoid) carcinoma was the most common type of malignant pathology, occurring in 7 of 11 patients. Two cases remain unclassified as to the type of carcinoma.

Bleeding, ulceration, and overgrowth are symptoms which may be suggestive of malignancy. Carcinoma in a pilonidal sinus is slow in growing and not prone to metastasize early. The surgical procedure consists of a wide excision extending 2 in. away from all pathological tissue and proceeding deeply down to the periosteum of the sacrum and coccyx and the gluteal fascia.

A more thorough gross and microscopic examination of pilonidal sinus specimens may reveal more carcinomas. A 13th case of pilonidal sinus carcinoma is herewith added to the surgical literature, the second case to be reported by us.

FOLLOW-UP STUDY ON A GROUP OF OLDER AMPUTEE PATIENTS

Carrie E. Chapman, M.D., Howard F. Palmer, M.S.W., Dorothy M. Bell, M.S.W.
and
Arthur A. Buckley, A.B., Oakland, Calif.

Detailed interviews were held with 51 amputees followed for varying periods after fitting of prostheses and release from hospital. Psychological factors affecting attitude and motivation seemed to be operating to various degrees. Favorable morale regarding value and use of the prosthesis by individuals appeared to be related to degree of change in physical condition, mode of living, and restriction on activities. It is believed worthwhile to provide prostheses with assistive devices for older amputees in order to help them remain more functional in their self-care, ambulation, and posthospital adjustment.

With the increasing number of older patients in the hospital population, it is pertinent to study various aspects of treatment and the outcome as it relates to such individuals. The purpose of this study was to obtain follow-up data concerning the posthospital adjustment of a group of older patients for whom the amputation of a limb or limbs had been necessary. The major areas investigated were physical status, mortality trends, personal and socioeconomic adjustment, and the extent to which a prosthetic appliance had been prescribed and was actually being used.

Patients included in this study were 55 years of age or older at the time of surgery and had been out of the hospital at least one year by the time of the follow-up interview. Through the assistance of the medical record librarian, cases were identified and initial data entered on work sheets for amputee patients who were in the designated age range and who had been discharged from this 712-bed general medical and surgical hospital, the Veterans Administration Hospital, Oakland, Calif., between Jan. 1, 1950, and April 30, 1955. There were 53 such patients. We were able to obtain follow-up information on 51 men, who comprised the number in this study.

The method of investigation consisted of two parts: a review of the hospital records and a follow-up survey. Clinical, physical medicine and rehabilitation, and social work service records were examined concerning pertinent areas which were uniformly reported. A schedule was prepared and a follow-up survey was carried out through social work service. An essential part of this was a personal interview with each ex-patient as a means of making observations and of getting first-hand information.

Hospitalization Data

Background Information.—All 51 amputees were males. Sixteen patients were between the ages of 55 and 59.9 years, 22 between 60 and 64.9, and 13 over 65 (one man was 82). The mean age was 63.1; the median age was 62.0 years. Three-fourths of these patients were under 65 years of age. Information concerning marital status and mode of living prior to admission to the hospital is combined in *table* 1.

One-half of the patients were married. All but two of these had been living at home. One had been at a state veterans home; the other, who had been in a Veterans Administration domiciliary, became ill when on holiday leave to visit relatives and was admitted to the hospital. Twenty-five patients were single, divorced, or widowed, and for them there was a diversified pattern in mode of living. Fifteen had lived by themselves in an apartment, room, hotel, or cabin; five had been residing with a relative; four were transferred for hospital treatment from a state veterans home; and one was transferred from another hospital after a cardiovascular accident.

Ten of these 51 patients who were under the age of 65 were reported to have been employed prior to admission. Of those patients over that age, none was reported to have worked for some time. This employment picture appeared to be related primarily to conditions in the labor market affecting older workers and to the high incidence in this group of chronic illness which imposed limitations on occupational activity.

Major Pathological Condition and Reason for Amputation.—A characteristic of this group was the prevalence of multiple diagnoses. The major pathological condition was arteriosclerotic cardiovascular disease in 23, general arteriosclerosis in 10, diabetes mellitus with arteriosclerosis obliterans in 5, embolism and/or thrombosis in 5, traumatic fracture in 2, chronic osteomyelitis in 2, carcinoma in 2, thromboangiitis obliterans in 1, and traumatic arthritis in 1. The predominant major illness was arteriosclerotic cardiovascular disease, which occurred in 45.1% of the total number of patients. Those with some type of major arteriosclerotic involvement

---

Chief, Physical Medicine and Rehabilitation Service (Dr. Chapman), Chief, Social Work Service (Mr. Palmer), Clinical Social Worker (Miss Bell), and Rehabilitation Coordinator (Mr. Buckley), Veterans Administration Hospital.

numbered 38 (74.5%) of the patients studied.

A trend in connection with age appeared when compared with diagnostic groupings. Of the 38 patients suffering from a major arteriosclerotic involvement, 78.9% were 60 years of age or older. For the 13 having other major pathological conditions, 61.5% were under 60.

By far the most frequent complication which was the reason for performing an amputation was that of gangrene. This occurred in 37, or 72.5%, of the cases. There were four instances of osteomyelitis; three each of ulcer and embolism; and one each of vascular insufficiency, nonunion old fracture, purulent drainage, and epidermoid carcinoma.

Fifteen patients had sympathetic blocks, 4 of them having had more than one block; 17 patients had sympathectomies, of whom 5 had bilateral sympathectomies. Six of the above 32 had both a sympathetic block and a sympathectomy. In spite of these therapeutic surgical interventions to improve circulation, it was still necessary to perform an amputation at a later date on all of these patients.

TABLE 1.—*Marital Status and Mode of Living of Patients Prior to Admission to VA Hospital*

	Patients					
Mode of Living	No	%	Married	Single	Divorced	Widowed
With own family......	24	47.1	24	..	..	..
By self................	15	29.4	..	9	4	2
Domiciliary setting....	6	11.8	2	..	3	1
With relative..........	5	9.8	..	3	1	1
Other hospital.........	1	1.9	..	..	..	1
Total................	51	100.0	26	12	8	5

Site of Amputation.—The site of amputation was above the right knee in 24, above the left knee in 14, bilateral in 10, upper part of the left arm in 2, and below the left knee in 1. There was a preponderance of amputations above the knee on the right side. It was thought that one factor affecting this might be poor sitting posture, namely, with the leg on the dominant side being crossed more often.

Of the 10 bilateral amputees, 9 had a major arteriosclerotic involvement. Two had double above-knee amputations while hospitalized, and eight had had previous amputations. For these eight, the time intervening between the two surgical procedures tended to fall into two patterns; for five the interval was from 12 to 24 months, and for three it was between 56 and 62 months. The resulting situation was that, of the 10 bilateral amputees, 6 had both amputations above the knee and 4 had one above-knee and one below-knee amputation. The high incidence of amputations above the knee, whether unilateral or bilateral, posed a greater problem in terms of rehabilitation and ambulation training.

Deaths in the Hospital.—Four of the 51 patients died in the hospital. All had suffered from arteriosclerotic cardiovascular disease. Their ages were 63, 68, 71, and 78, all being older than the average age for the total group. There were, then, 47 amputee patients who were discharged from the hospital.

Patients Receiving Prosthetic Appliances.—The decision as to whether or not a patient was going to be issued a permanent prosthesis was based primarily on a careful medical appraisal of the nature and extent of the patient's illness or injury in relation to his physical and mental capacity to use a prosthesis and the effect on his functional efficiency in performing activities of daily living outside of the hospital environment.

Such an evaluation required a thorough and comprehensive review of not only all the medical factors involved but also the nonmedical aspects. In this respect, the importance of peripheral vascular tests cannot be overlooked as a base line in evaluating the circulation of the limb or limbs concerned. These tests were significant not only in determining the necessity for amputation but as a follow-up evaluation of the condition of the extremity or extremities under medical and physical therapy treatment.

Of the 47 patients, 26, or 55.3%, were fitted with and trained in the use of prosthetic appliances. This included one arm amputee. For the second arm amputee, the stump was too short for a prosthesis to be feasible. There was variation according to age and major pathological conditions in patients who received prosthetic appliances. Of the patients aged 55 to 59.9 years, 10 received prostheses and 6 did not; of those aged 60 to 64.9, 14 received prostheses and 7 did not; and of those aged 65 and over, 2 received prostheses and 8 did not. Of the 34 patients with a major arteriosclerotic involvement, 15 (44.1%) received prostheses; of the 13 with other major pathological conditions, 11 (84.6%) received prostheses.

Of the 10 bilateral amputees, prostheses were issued to 3. Two were 55 and one was 59 years old. One used a prosthesis which he had, plus crutches. One used an old prosthesis plus a new one and crutches, and the third was issued an above-knee-right and a below-knee-left prosthesis and crutches.

Physical Medicine and Rehabilitation Prosthetic Training Program.—The prosthetic program comprised four phases. Phase 1—bed training—consisted primarily of body positioning, general conditioning, and bedside stump exercises. Phase 2—clinical training—consisted of preambulatory and crutch training, bandaging, and exercises such as mat, general conditioning, and Buerger-Allen exercises. Phase 3—pylon training—consisted of progressive resistive exercises to stump, pylon training, balancing in parallel bars, and continuation of Buerger-Allen exercises, bandaging, and mat exercises as indicated. Phase 4—prosthetic training—consisted of a continuation of all activities of phase 3, when indicated, except that prosthetic training was conducted instead of pylon training. Concurrent with this prosthetic training, the patients participated in an intensive self-care program.

The use of a pylon in ambulation training was one of the most important phases of the amputation program. Generally, about six to eight weeks after surgery a plaster bucket was made of the patient's stump, either above-knee or below-knee. The plaster bucket was then inserted into the leather cuff of the pylon, which could be adjusted to the individual patient's needs.

Pylons have proved advantageous in our program in (*a*) shrinking and seasoning a stump for preparation of a permanent prosthesis; (*b*) retraining of the proprioceptive tracts during the shrinking period, thus enabling the patient to build confidence in balance and coordination while ambulating; and (*c*) eliminating the cost of expensive bucket adjustments which are necessary when preparing a stump during training for a permanent artificial limb.

Social Work Service.—A number of these patients came to the attention of social work service at an early point as the result of personal difficulties connected with hospitalization or impending surgery or because of financial or family difficulties. Because of social, economic, or emotional complications, other patients became known later on. Some requests for a social evaluation, as a part of rehabilitative or treatment planning, were made initially and some at a subsequent point in hospitalization. Despite the specific problem presented, the factors of the threat represented by amputation, the imposition of limitations of activity, and concern about the future were reactions with which the patients needed help. In the process of discharge planning, it was necessary to mobilize to the utmost the capacities existing in the patient and his family, including all relatives, and to utilize all available community resources. With a number of these older patients a problem was to conteract their reluctance to leave the hospital. The general pattern was not so much one of continuous activity with the patient but rather that of giving the needed services according to an integrated timing with on-going treatment and rehabilitative planning.

TABLE 2.—*Period of Hospitalization of Patients*

	Patients, No.	Days Hospitalized, Median No.	Days from Amputation to Discharge, Median No.
With prosthesis	26	192.5	133.0
Without prosthesis	21	120.0	90.0
Total	47	154.0	112.0

Period of Hospitalization.—There was a wide range in the number of days of hospitalization, varying from 52 days to periods of 573 and 579 days for two patients with resistive bone infections. The mean was 147 days, there being four patients with that period of hospitalization. Because of the two atypical cases, the median, rather than the mean, was computed for each group (table 2). For the total group the median number of days hospitalized was 154.0, and the median interval between the date of amputation and the date of hospital discharge was 112.0 days. It is of interest to note that the difference in number of hospital days from amputation to discharge was only 43 days higher among those who had received prostheses than those who had not.

Capacity for Self-care and Ambulation.—At the time of leaving the hospital 32 of the 47, or 68.1%, were completely able to care for their personal needs, while 15 needed partial assistance. Since the capacity to ambulate was not involved for the two arm amputees, the number reviewed here is 45. The categories used were based on the prevalent or customary way of getting around.

Twenty-five leg amputees had been fitted with prostheses. One ambulated with the prosthesis alone, 10 with the prosthesis plus a cane, and 13 with the prosthesis plus crutches. One 71-year-old man, who was insistent that he be given a prosthesis, was able to use it only part of the time with the aid of crutches, but he actually depended on crutches to get about, and was so classified. Six ambulated with crutches alone. Fifteen got about in a wheel chair, seven of them being the bilateral amputees for whom prosthetic appliances were not believed to be advisable. All of these patients were given intensive self-care training so as to be functional in a wheel chair.

Posthospital Living Arrangements.—Of the 47 patients who were discharged, 21 of the 24 married men returned to live with their own family. Six single, three divorced, and one widowed went to live by themselves in an apartment, room, hotel, cabin, or a place where they had room and board. This mode of living had been their pattern in the past and was one which they preferred to try again on leaving the hospital. Of the eight who went to a domiciliary setting or state veterans home (three of whom were married, one single, two divorced, and two widowed), five had been transferred from there, and this was the most feasible discharge plan for an additional three. Of the seven who went to live with relatives (four of whom were single and three divorced), three went to a sister, two to a daughter, one to a son, and one to his wife's mother. One single man was transferred to a county hospital for care of chronic conditions.

When the mode of living prior to admission was compared with that at the time of discharge, it was found that the percentage of those in their own home remained about the same. There was a drop in the number of those living by themselves and an increase for those going to a domiciliary setting or to live with a relative.

Follow-up Data and Survey

Mortality Data.—On completion of the follow-up survey, it was found that, of the 47 patients who had been discharged from the hospital, 15 had died. These, added to the 4 who had died in the hospital, totaled 19, or 37.3%, of the original 51 patients in the study.

Table 3.—*Major Pathological Condition of Patients Who Died*

Major Diagnosis	Total	Died No.	Died %
Diabetes mellitus with arteriosclerosis obliterans	5	3	60.0
Arteriosclerotic cardiovascular disease	23	12	52.2
General arteriosclerosis	10	2	20.0
Embolism and/or thrombosis	5	1	20.0
All other	8	1	12.5
Total	51	19	37.3

Of the 15 who died after having been discharged, 9 had been readmitted to this hospital for a total of 21 times, usually for treatment of the same conditions or for complications connected with them. In four instances a stump revision was necessary. For one patient with general arteriosclerosis the amputation of the other leg had to be done within six months. Some of the patients died in this hospital, but a number did not; therefore, we do not have uniform data as to the specific cause of death.

A correlation between major pathological condition and mortality trend appears in table 3. The mortality trend was considerably greater for those in whom arteriosclerotic involvement was complicated by a diabetic or a cardiovascular condition. It was the same for those having general arteriosclerosis and those with embolism and/or thrombosis and was much less for those with other diagnoses.

The mortality trend according to unilateral and bilateral amputees and in regard to those having and those not having prostheses is given in table 4. The intervening time for the total number who died after leaving the hospital ranged from 14 to 45 months, with an average of 27.9 months, or well over two years. The average for the bilateral amputees was slightly higher than for those with one leg amputated.

Of the total, four had prostheses when they left the hospital. Subsequently one unilateral and one bilateral amputee had been fitted with a prosthesis. For another patient, the amputation of the remaining leg had been necessary and an additional prosthetic appliance had been prescribed. Thus, the total having prostheses became six; these lived from 24 to 45 months, or an average of over three years. The nine who had no prostheses lived from 14 to 35 months, with an average of less than two years.

As to age, the average time out of the hospital for the 15 amputees who later died was 32.0 months for six in the 55-to-59.9-year age group, 28.2 months for the five in the 60-to-64.9-year age group, and 21.5 months for the four who were 65 years of age or older.

Method of Survey.—Of the patients discharged, 32, or 68.1%, were interviewed by a social worker at their place of residence. In this way the items in the survey schedule were covered and an opportunity was provided for direct observation. These contacts were usually made without prior notification to the ex-patient. Twenty who lived within the geographical area around the hospital were seen by one of us (D. M. B.). Nine who were living in different parts of the state and three who were in other states were interviewed by social workers from various Veterans Administration regional offices. In nearly all instances, these former patients felt that the visit was an indication of interest in how they were doing and they were quite willing to discuss their situation.

Period Between Hospital Discharge and Follow-up Interview.—One of the criteria for selection of this group was that each patient be out of the hospital at least one year by the time of the follow-up survey in 1956. The actual interval between hospitalization and follow-up ranged from 14 to 72 months, with the frequency distribution being fairly even. The mean was 39.4 months and the median 36.0 months.

Physical Status.—Considering the age of these amputees and the prevalence of degenerative disorders, it was not surprising that 20 of the 32 had been rehospitalized here or elsewhere. Seven, including three who had been rehospitalized, had received treatment from a private physician, and one had been treated at a county hospital. Of the 20 who were rehospitalized, 9 experienced difficulty with the stump, 5 had a stump revision, 2 reported continuance of phantom pain, and 3 (all of whom had arteriosclerotic cardiovascular disease) required an above-knee amputation of the other leg within 11, 14, and 24 months respectively. Of the total of those in the follow-up survey and those who died after having left the hospital, nine, or 19.1%, had to have a stump revision, and for four, or 8.5%, the amputation of the other leg became necessary.

Table 4.—*Number of Months Between Hospital Discharge and Death of Fifteen Patients*

Site of Amputation	Patients, No.	Mo. Intervening, Av. No.
Unilateral—above knee	9	26.2
With prosthesis	3	33.3
No prosthesis	6	22.7
Bilateral—above knee	6	30.5
With prosthesis	3	42.3
No prosthesis	3	18.7
Total	15	27.9
With prosthesis	6	37.8
No prosthesis	9	21.3

Inasmuch as the individual's feeling about his physical condition played an important part in his general attitude and adjustment, this point was covered with each amputee. Fourteen reported their conditions were good, 13 fair, and 5 poor. These subjective reactions appeared to be related not only to the presence of symptoms or of discomfort and the recency of having received treatment but also to their ability to ambulate or to move about and to their capacity for caring for their personal needs.

It was interesting to note that only four of the amputees were still protesting the loss of a limb. The others had, in varying degrees, and better for the unilateral than the bilateral amputees, come to a psychological acceptance of the loss of their limb or limbs. One man, an obviously poor candidate for a prosthesis, was resentful because he had not been given one. There seemed to be the possibility that his feeling was related to others having been issued prosthetic appliances in the domiciliary where he was living. Three former patients expressed the reaction that their hospitalization had not included sufficient treatment or had not been long enough. On checking the records, however, it was found that considerable effort had been expended in their treatment, that they had all been trained in the use of their prostheses, and that they had all been hospitalized much longer than the average.

Table 5.—*Mode of Living and Marital Status of Amputees at Time of Follow-up*

	Patients					
Mode of Living	No.	%	Married	Single	Divorced	Widowed
With own family......	14	43.8	14	..	..	..
With a relative........	6	18.7	1	3	1	1
By self..................	4	12.5	..	2	2	..
Domiciliary setting....	4	12.5	..	..	2	2
Other hospital.........	4	12.5	2	1	1	..
Total................	32	100.0	17	6	6	3

Ability for Self-care.—The ability for self-care at the time of follow-up compared with that at time of leaving the hospital was as follows: There was a drop in the number of those who were capable of taking care of their own needs (from 24 patients to 19), a slight increase among those requiring partial assistance (from 8 patients to 9), and a definite increase for those needing full-time care (from no patients to 4). Of the four in the last category, one was a bed patient at home, and three were in the hospital unit at a state veterans home.

With age and physical limitations, there appeared to be a decrease in capacity for self-care and an increase in the need for arrangements where more care or supervision could be provided. This observation was reflected also in the material in the next section.

Mode of Living and Marital Status.—Table 5 shows data on the mode of living of the amputees at the time of follow-up. Of the 17 married men, 14 were living with their families, 1 was with a relative, and 2 were hospitalized at a state veterans home. Of the 15 who were either single, divorced, or widowed, 5 were living with a relative, 4 were living independently, 3 were residing at a state veterans home, one was at a Veterans Administration domiciliary, and 2 were hospitalized at a state veterans home.

A comparison of percentages as to the mode of living at the time of admission, at the time of hospital discharge, and subsequently at the time of follow-up revealed the following trends: The number of those living with their own family remained the most constant, with only a small decrease in the percentage; there was a marked drop in the number of those living alone and an increase for those in a domiciliary setting. Twice the number were living with a relative, while there was a noticeable increase in number of those in another hospital.

Only 6 of the 32 amputees had made shifts in living arrangements between the time of hospital discharge and follow-up. Two had merely moved from the home of one relative to that of another. Four had been living alone; of these, two had moved to the home of a relative and one had gone to a Veterans Administration domiciliary and one to a state veterans home. This relative lack of mobility may be partially explained by the age and physical disability of this population. It also indicated that the plan at the time of leaving the hospital, if suitably made, was likely to be the continuing living arrangement for a person in a group such as this.

Vocational and Financial Situation.—One amputee was gainfully employed full time at reconditioning valves in his own shop. Three others were working part time; one did repair work and saw-filing in his workshop at home, one supported himself and his wife by operating a concession in an amusement park, and the third operated a lodge in the hills where he lived during the hunting season. All four men were between 61 and 66 years old, all had an above-knee amputation of the right leg, and all had been fitted with prostheses. They had been out of the hospital for 14, 26, 36, and 62 months respectively. They all expressed the opinion that having a prosthesis was most helpful in enabling them to pursue a vocational activity. Their general attitude was observed to be very good.

Financially, it was found that two men were fully self-supporting. Another received Social Security and Old Age Assistance benefits. The remaining 29 were in receipt of Veterans Administration benefits. For 14 of these, this was their sole source of income. This income for the other 15 was supplemented by Social Security or retirement benefits, by the wife working in five instances, by part-time work for two, and by Old Age Assistance for one. Of the 32 amputees, 6 who were married and 4 of the others reported having a difficult time financially. Twenty-two stated that they were managing adequately.

Recreational Activities.—The recreational activities of this group seemed to be influenced by the individual's capacity to move about, his attitude toward his physical condition, and his living situation. An examination of the changes in recreational patterns was not possible inasmuch as there was little information available regarding recreational activities prior to the amputation. Our observations will be limited to the activities in which these amputees were engaging when they were interviewed for this study.

Recreational activities were classified as active or passive. Active recreation included gardening, walking, hiking, fishing, dancing, bowling, or such creative hobbies as wood carving or metal work. The passive forms of recreation were reading, listening to music, watching television, attending motion pictures, or card playing.

Thirteen amputees engaged in active types of recreation (this, of course, did not exclude passive recreation), while 19 were interested only in passive amusements. Of those who engaged in active recreation, 10 had prostheses and 3 did not. It appeared that a family living situation was more conducive to active recreational activities.

Table 6.—*Mode of Ambulation*

Mode	When Leaving Hospital Total No. of Patients	When Leaving Hospital Unilateral	When Leaving Hospital Bilateral	At Follow-up Total No. of Patients	At Follow-up Unilateral	At Follow-up Bilateral
Prosthesis alone or plus aid	19	17	2	15	14	1
Crutches alone	4	4	..	4	4	..
Wheel chair	7	4	3	9	4	5
Bed patient	..	..	..	2	..	2
Total	30	25	5	30	22	8

Ability to Ambulate or to Move About.—The capacity to ambulate did not affect the two arm amputees; therefore, the number considered in this section will be the 30 leg amputees. At the time they left the hospital there were 24 above-knee, 1 below-knee unilateral, and 5 bilateral amputees. Between that time and the follow-up interview, it had become necessary to remove the other leg for three above-knee amputees, which increased the number of bilateral amputees to eight. In addition, 21 amputees in the follow-up survey had been fitted with prostheses while hospitalized, but afterward two others obtained prostheses, making a total of 23 by the time of follow-up.

Considering the changes mentioned above, comparative data in table 6 regarding typical mode of getting about are based on both that at the time of leaving the hospital and that at the time of follow-up. There were no over-all changes among the unilateral amputees in regard to mode of getting about except for three who had required the amputation of the other leg. Of the eight bilateral amputees, however, only one (who had an above-knee and Symes amputation) was able to ambulate adequately, whereas five were confined to a wheel chair and two had become bed patients.

Next, the mode of moving about was examined more specifically, and the extent of ability to get about was appraised (table 7). At the time of leavin the hospital only one amputee had been able to ambulate with his prosthesis alone. At the time of follow-up this was true for eight, who could go as far as they wished or walk for moderate distances. The seven who ambulated with their prostheses plus a cane or crutches did equally well, except for two who were restricted to moving about their quarters. Of the 13 who got about on crutches or in a wheel chair, 10 moved about their quarters only, and two had become bed patients.

Table 7.—*Ability to Move About*

Mode	Total No. of Patients	As Much as Desired	Moderate Distances	Around Quarters Only	Not at All
Prosthesis alone	8	5	3	..	..
Prosthesis plus cane	4	2	2	..	..
Prosthesis plus crutches	3	1	..	2	..
Crutches alone	5	1	1	3	..
Wheel chair	8	..	1	7	..
Bed patient	2	..	..	..	2
Total	30	9	7	12	2

Extent of Use of Prosthesis.—Of the 32 amputees, 24, or 75%, had received prostheses by the time of the follow-up interview (table 8). This number included one arm amputee who used his prosthesis some each day but who tended to do most things with his uninvolved arm. Thirteen, or 54.2%, were using their prosthetic appliances regularly and consistently, and 3 used theirs some each day, but not as extensively as the 13.

That a certain amount of complications for a group of this age could be anticipated was borne out by their experiences. Nine reported pain, swelling, dermatitis, or other trouble with their stumps; two had a continuation of phantom pain; and five required stump revisions. Twelve, or one-half, reported having mechanical trouble or difficulty with the fit of the prosthesis. Most had had theirs repaired; two had been issued new prostheses.

Table 8.—*Extent of Use of Prosthesis*

Extent	Total No. of Patients	Unilateral Prosthesis	Bilateral Prosthesis
Regularly and consistently	13	12	1
Some each day	3	3	..
Infrequently	2	2	..
Not at all	6	5	1
Total	24	22	2

It appeared, however, that such physical or mechanical complications did not wholly explain the individual's adjustment to and use of the prosthesis. Psychological factors affecting attitude and motivation seemed to be operating to various degrees. Difficulty with stumps or prosthetic appliances did not appear to assume as much significance for those who used theirs consistently as it did for some of the others. For example, the three men who used their prostheses some each day were reported as being bored and inactive, afraid because of several falls, and complaining and seeking sympathy. Of the two who used their appliances only infrequently, one was reported to have "given up." His wife stated that he used his appliance very little because he "was afraid" and "had no nerve." The other man tended to project all blame for his situation outside himself and doubted if he "could do anything about it." This aspect also appeared to be operating with two of the amputees who were not using their prostheses at all.

Of the six men who were not using their prosthetic appliances at all, two, aged 62 and 71, both with arteriosclerotic cardiovascular disease, had within 11 and 14 months had an amputation of the other leg and had been confined to a wheel chair. Two other men, one aged 55 who had arteriosclerotic cardiovascular disease and one aged 59 who had diabetes mellitus with arteriosclerosis obliterans, had had cerebral accidents and were wheel-chair patients.

The remaining two had discarded their prostheses. One, a 60-year-old single man and an alcoholic, was living on skid row and getting about on crutches. The other, a 65-year-old single man who was living with a relative, depended on crutches and had never tried to use his prosthesis. He said that he felt he was "about to die" and that he "did not care anymore."

Thus, it was found that, of the 24 amputees who had prostheses, 16, or 66.6%, used theirs regularly or some each day. Four, or 16.7%, had been forced to discontinue the use of theirs because of another amputation or because of a stroke. Four, or 16.7%, used their prosthetic appliances only infrequently or had discarded them.

General Attitude.—Based on the various aspects which have been discussed and on statements made by the 32 amputees interviewed, a composite evaluation showed the general attitude was good for 13, fair for 12, and poor for 7. The majority of those whose attitude was good were found to be experiencing less physical discomfort or symptomatology, caring for their own personal needs, living with their own family or with a relative, engaging in a more active type of recreation, and capable of ambulating in a satisfactory manner. To the extent that negative changes occurred in physical condition, mode of living, ability to get about, and restrictions in activities, the attitude tended to become fair and in a few instances poor.

Summary

A study, based on a review of hospital records and on a follow-up survey, was made on 51 amputee patients who at the time of amputation were 55 years of age or older. There was a prevalence of chronic conditions and of multiple diagnoses. The most frequent complication necessitating an amputation was gangrene for slightly under two-thirds of these amputees. After a careful evaluation, including physical condition, age, and personal and socioeconomic factors, 26 of 47 patients were fitted with prosthetic appliances while hospitalized.

Data relative to physical status at the time of leaving the hospital compared with those at the time of follow-up revealed a considerably shifting picture. For example, evidence obtained concerning those who had died indicated that a fairly large number had required further medical care, had had trouble with stumps, or had had difficulty with prosthetic appliances. Nineteen patients (37.3%) had died, 4 during the period of hospitalization when the amputation was performed and 15 after having been discharged. There was a higher incidence of mortality for those whose arteriosclerotic involvement was complicated by a diabetic condition or by cardiovascular disease.

In the follow-up survey, 32 (62.7%) former amputee patients were interviewed at their places of residence. The time intervening since the termination of hospitalization ranged from 14 to 72 months. Four men who had been fitted with prostheses were gainfully employed. In all, 22 were managing financially, usually with the assistance of various benefits.

The number of amputees living with their own family remained the most constant; twice as many were living with relatives. There was a marked drop in the number living by themselves and an increase for those in a domiciliary setting or hospital. Nineteen men were completely self-caring, nine required partial assistance, and four needed full-time care. Thirteen engaged in active and 19 in passive type of recreation.

Twenty-four of the 32 men had, by the time of the follow-up survey, been fitted with prosthetic appliances. Of these, two-thirds were using their prostheses regularly and for part of each day, one-sixth had become unable to use theirs, and one-sixth preferred not to use theirs.

Favorable morale or general attitude appeared to be related to less extensive changes regarding physical condition, mode of living, ability to ambulate, and restrictions on activities. It is believed that it was worthwhile to have given these older amputees the benefit of the use of prostheses with assistive devices in order to help them remain more functional in their self-care, ambulation, general activity, and posthospital adjustment.

OBSERVATIONS ON OPHTHALMODYNAMOMETRY

J. Lawton Smith, M.D., Irving H. Zieper, M.D.
and
David G. Cogan, M.D., Boston

The use of the Bailliart ophthalmodynamometer makes it possible to apply increasing, measured pressure to the anesthetized sclera while the observer watches the retinal arteries. This constitutes a rapid, safe test for internal carotid artery insufficiency. Comparison of the ophthalmic artery pressures obtained when the patient is standing with those obtained when he is supine enhances the sensitivity and diagnostic usefulness of the test. Eleven cases are described to illustrate the significance of the results. Indications for ophthalmodynamometry include clinical evaluation of cerebrovascular disease and amaurosis fugax, evaluation of endarterectomies and carotid ligations, evaluation of response to anticoagulant therapy in carotid disease, and investigation prior to arteriography.

The clinical usefulness of ophthalmodynamometry in the early diagnosis of internal carotid arterial insufficiency has become increasingly important with the recent advent of more effective therapy. A dramatic reduction in the incidence of transient ischemic attacks in both the carotid and basilar-vertebral system has been reported[1] with bishydroxycoumarin (Dicumarol) and heparin-like substances. Endarterectomy[2] and other techniques have been proposed in a surgical attack on carotid atheromatous disease. The high incidence of extracranial carotid occlusion has been emphasized by the pathological studies of Fisher.[3] This has brought forth the realization that many stroke cases formerly attributed to discouraging and inaccessible vascular occlusions are not infrequently due to focal atheromatous disease in the neck.

An intensive study in cerebrovascular disease is being conducted in the Massachusetts General Hospital under the direction of Dr. C. Miller Fisher. Ophthalmodynamometry has been done in the majority of these cases and has proved of considerable value in detecting and following the course of carotid artery disease. From the data accumulated to date, several observations which appear to merit reporting have been made. These concern (1) the effects of posture on the ophthalmodynamometric diagnosis of carotid insufficiency, (2) the importance of determining systolic as well as diastolic ophthalmic arterial pressures, (3) the changes in ophthalmic artery pressure with anticoagulant therapy in carotid disease, (4) the effect of auricular fibrillation on ophthalmodynamometry, and (5) the ability to follow the effectiveness of progressive carotid ligation and of carotid endarterectomy by serial ophthalmodynamometric determinations. Perry and Rose[4] have recently reported on the correlation of ophthalmodynamometric values with the systemic blood pressure. Analysis of our data in this regard will be presented in a subsequent communication. The purpose of this report is to present the above observations and to illustrate them briefly with selected cases.

The technique of ophthalmodynamometry used throughout this study is as follows: With full mydriasis (with a 1% solution of cyclopentolate [Cyclogyl] hydrochloride) and topical anesthesia (with a 0.5% solution of proparacaine [Ophthaine] hydrochloride), an observer watches for the onset of retinal arterial pulsation and subsequently for the cessation of pulsation as an assistant exerts increasing pressure on the sclera with a Bailliart ophthalmodynamometer. The former is recorded as diastolic and the latter as systolic ophthalmic artery pressures. The observations are made by indirect ophthalmoscopy, and each end-point is checked three times for reproducibility. (Binocular indirect ophthalmoscopy facilitates testing by allowing adequate working distance for the assistant, minimizing the effect of ocular movement by means of a larger field, and possessing greater illumination and the advantages of stereopsis.) In our experience, when the pressures are within the normal range a reproducible difference of over 10 units systolic and/or 6 units diastolic has been clinically significant. This is in agreement with Hollenhorst's[5] report that a difference of 10 mm. Hg or more in the ophthalmic arterial pressures, either systolic or diastolic, indicates definite reduction of carotid flow on the side of lower pressure.

Posture Test

The possibility that postural changes might yield significant information was suggested by the fact that some patients with occlusive carotid disease

---

From the Howe Laboratory of Ophthalmology, Harvard University Medical School, Massachusetts Eye and Ear Infirmary. Dr. Zieper is a clinical fellow in cerebrovascular disease, Department of Neurology, Massachusetts General Hospital.

have noted amaurosis fugax and other ischemic symptoms to be related to changes of posture. A test was proposed by one of us (D. G. C.) to study this point. It consists of measuring the blood pressure in both arms by conventional means with the patient in the supine position. The systolic and diastolic ophthalmic artery pressures are then determined by the technique given above. The patient is then placed in the standing position, and blood pressures are again taken in both arms and in both eyes.

The following four cases were selected from a larger series to show that a significant difference in the arterial pressure of the two eyes may be brought out by measurements in different positions. The significant disparity was evident when the patient was in the supine position in cases 1 and 2 and in the erect position in case 3. In the fourth case definite variations with posture were shown, but a greater disparity was seen when the patient was in the supine position initially and in the erect position three months later.

Case 1.—A 45-year-old man entered the Massachusetts General Hospital because of weakness of the left foot of 12 days' duration. Positive findings were hyperreflexia of the left knee and ankle, Babinski's response on the left, absence of all pulses below the femoral arteries, soft bruit over the left eye, increased spinal fluid protein level (66 mg. %), and a mildly diabetic glucose tolerance curve. The clinical impression was of a right internal carotid artery thrombosis with infarction in the territory of the anterior cerebral artery. Preliminary ophthalmic arterial pressures showed a lower diastolic pressure on the right side, but the values are not included in the present series because systolic measurements were not made and the effects of posture were not studied.

The patient stopped smoking, was put on a diabetic diet, and had shown a good clinical recovery when he returned four months later. At that time the following measurements were made: right arm, 140/85 mm. Hg supine and 126/76 erect; left arm, 178/90 supine and 134/70 erect; right eye, 90/43 supine and 80/40 erect; and left eye, 110/54 supine and 87/47 erect.

Comment.—This patient is believed to have had symptoms due to occlusive disease of the right carotid artery. A bruit was heard over the contralateral eye, a finding which has been previously reported in carotid insufficiency.[6] It is noteworthy that only a borderline inequality of ophthalmic artery pressures was present when the patient was in the erect position but a difference of 20 mm. Hg systolic and 11 mm. Hg diastolic was evident when he was in the supine position.

Case 2.—A 65-year-old man, with a coin lesion visible in his chest roentgenogram, developed weakness of the left hand and forearm while being prepared for thoracotomy. The monoparesis worsened over a four-hour period. On questioning, the patient recalled that previously he had had transient weakness in the left hand and two attacks of amaurosis fugax in the right eye. No ocular bruit was heard, although a bruit was audible over the right carotid artery. The visual acuity, fields, and fundi were normal. A diagnosis was made of developing right carotid thrombosis. The posture test revealed the following pressures: right arm, 130/70 mm. Hg supine and 106/68 erect; left arm, 140/80 supine and 110/70 erect; right eye, 62/30 supine and 42/25 erect; and left eye, 92/39 supine and 56/30 erect. The patient was put on bishydroxycoumarin therapy, and the left-sided hemiparesis slowly improved. Later surgical exploration revealed adenocarcinoma of the right upper lobe.

Comment.—This patient apparently developed an acute exacerbation of a chronic right carotid arterial insufficiency. The striking ophthalmodynamometric finding was a difference of only 14 mm. Hg systolic pressure when the patient was in the erect position but 30 mm. Hg when he was in the supine position.

Case 3.—A 45-year-old woman was admitted because of transient blackouts in the left eye and a history of angina pectoris. Two years previously, shortly after the death of a 37-year-old brother from myocardial infarction, the patient began having blackouts in the left eye, increasing in frequency, and subsequently occurring at least daily. They seemed to be related to sweeping, sitting up, or eating large meals. Only one attack had occurred while she was lying down, and this was mild.

Examination revealed extensive xanthelasma of the eyelids, xanthoma of various tendons, and a decreased femoral pulse rate on the right. Serum cholesterol level was 494 mg. %. A diagnosis was made of familial xanthomatosis with hypercholesteremia, atheromatosis, and occlusive left carotid artery disease. The posture test revealed the following pressures: right arm, 132/78 mm. Hg supine and 108/64 erect; left arm, 128/80 supine and 110/68 erect; right eye, 84/48 supine and 85/44 erect; and left eye, 71/42 supine and 75/40 erect. The patient was placed on bishydroxycoumarin therapy, and a marked reduction in number and severity of attacks of amaurosis fugax resulted. Repeat posture test three and one-half months after bishydroxycoumarin therapy was started revealed these pressures: right arm, 150/84 mm. Hg supine and 124/50 erect; left arm, 148/80 supine and 120/70 erect; right eye, 98/40 supine and 106/43 erect; and left eye, 71/42 supine and 75/40 erect.

Comment.—Ophthalmodynamometric measurements made prior to therapy showed approximately equal pressures in both eyes when the patient was in the supine position but a gross inequality of systolic pressure (25 mm. Hg) when she was in the erect position. After anticoagulant therapy, the ophthalmic artery pressures were elevated in both eyes but the difference in pressure persisted. This elevation of pressure with anticoagulant therapy will be referred to below.

Case 4.—A 63-year-old man complained of transient episodes of blurred vision in the right eye for two years, with headaches and transient weakness in the left arm and leg for one year. He had also had intermittent claudication of the lower extremities. General physical and neurological examination gave normal findings except for absence of a pulse in the left arm. The visual acuity and fields were normal. Ophthalmoscopy disclosed slight pallor of the right optic disk, with an enlarged cup and a small area of neovascularization at the upper nasal margin of the disk. A diagnosis of right carotid insufficiency was made. The posture test revealed the following pressures: right arm, 150/90 mm. Hg supine and 140/90 erect; left arm, pressure unobtainable in both positions; right eye, 73/26 supine and 73/21 erect; and left eye, 83/38 supine and 79/26 erect.

The patient stopped smoking, and no further attacks of amaurosis fugax or claudication occurred. A routine hemogram revealed chronic lymphocytic leukemia. Repeat posture test three months after the first measurements showed these findings: right arm, 140/100 mm. Hg supine and 136/76 erect; left arm, pressure unobtainable in both positions; right eye, 95/38 supine and 84/33 erect; and left eye, 115/41 supine and 115/38 erect.

Comment.—Although this patient was found to have mild chronic lymphocytic leukemia and simple glaucoma, his chief complaints were related to generalized atherosclerosis and particularly to occlusive disease in the right carotid, left brachial, and both femoral arteries. His symptoms of amaurosis fugax in one eye with transient hemiparesis on the opposite side are typical of internal carotid disease. Inability to obtain a blood pressure in one arm and intermittent claudication were further evidence of generalized atherosclerosis. Of greatest interest were the ophthalmodynamometric findings which, while showing a consistently lower pressure in the right eye, revealed a greater difference when the patient was in the supine position on the first examination and in the erect posture three months later.

Systolic Ophthalmic Artery Pressures

The importance of systolic ophthalmic artery pressures has only recently been stressed.[7] The diastolic values are the ones customarily given, and when there is a significant difference between the two eyes measurement of the systolic pressures may not be necessary. Although determination of systolic pressure should be done rapidly and with care, no known injury to the globe has occurred in over 100 patients in whom this measurement has been made. That systolic measurements are of considerable importance is illustrated by the following two cases of carotid occlusion in which the diastolic values were approximately the same but the systolic pressures were grossly unequal.

Case 5.—A 66-year-old man had an episode of dizziness and a partial left homonymous hemianopsia two years prior to hospitalization for a fractured femur. Recently he had lost vision in his left eye and had developed coronary heart disease. Examination showed extensive retinal arteriolar narrowing and pallor of the left disk with vision in this eye reduced to 3/200. Blood pressure measurements made only with the patient in the supine position (because of the hip fracture) were as follows: right arm, 206/108 mm. Hg, left arm, 210/110, right eye, 150+/69, and left eye, 101/67.

Case 6.—A 50-year-old woman developed a bilateral carotid-cavernous fistula after an automobile accident. This was most marked on the left side, and ligation of the left carotid artery was done first in the neck and then intracranially. The ophthalmic artery pressures in the left eye were 100/30 mm. Hg before the ligation and 50/25 after this procedure.

Comment.—Cases 5 and 6 illustrate that diastolic pressures may on occasion be approximately equal while the systolic pressures are grossly unequal. The reverse does not appear to be the case, although one patient has been encountered with a definite difference in diastolic pressures in the two eyes but with both systolic values too high to determine on the Bailliart ophthalmodynamometer.

Anticoagulant Therapy

Marked symptomatic improvement in cases of internal carotid disease has been reported from treatment with bishydroxycoumarin and heparin-like substances.[1] The means by which this is accomplished is obscure, but in case 3 findings suggested that one of the results is a partial restoration of the arterial pressure. Thus, with bishydroxycoumarin therapy, the systolic pressure on the obstructed side rose 15 mm. Hg when measured with the patient in the supine position. Findings in another patient with occlusive carotid disease studied before and after anticoagulant therapy are given in case 7.

Case 7.—A 59-year-old man complained of intermittent blurred vision in either eye, paresthesias in either hand, transient confusion, and fatigability of two years' duration. The noteworthy ocular abnormality, apart from the ophthalmic artery pressures, was a myriad of tiny microaneurysms such as we have previously seen only with atheromatous pulseless disease. These were much finer and more numerous than those of diabetic retinopathy and resembled a rete mirabile on the retina. The arteries and veins themselves were not abnormal, and the fundi were otherwise normal.

The ophthalmodynamometric values were the lowest we have encountered but were approximately equal in the two eyes and approximately the same with the patient in supine or erect positions. A diagnosis of bilateral carotid occlusive disease was made, and the patient was started on bishydroxycoumarin therapy. Four weeks later, although the prothrombin time had been reduced to only 40% of normal, he was symptomatically definitely improved. The measurements before anticoagulant therapy were as follows: right arm, 116/60 mm. Hg supine and 130/80 erect; left arm, 134/90 supine and 110/86 erect; right eye, 35/21 supine and 25/15 erect; and left eye, 28/18 supine and 25/15 erect. After four weeks of anticoagulant therapy, measurements were as follows: right arm, 134/88 mm. Hg supine and 134/58 erect; left arm, 136/88 supine and 156/92 erect; right eye, 41/28 supine and 35/24 erect; and left eye, 34/25 supine and 36/20 erect.

Comment.—This patient had extraordinarily low ophthalmic artery pressures, presumably due to bilateral carotid disease. Treatment with bishydroxycoumarin resulted in a mild but significant rise in the ophthalmic artery pressures and considerable symptomatic improvement. Definitive opinion of the possible significance of these pressure changes after anticoagulant therapy must await a larger series of cases.

Auricular Fibrillation

We encountered great difficulty in obtaining consistent readings in a patient before realizing the significance of his cardiac arrhythmia. In five other cases of auricular fibrillation, a wide and variable range of ophthalmodynamometric readings was obtained on successive testing. In these cases, both systolic and diastolic pressures may have little meaning.

Carotid Ligation and Endarterectomy

The potential value of ophthalmodynamometry in carotid ligation and endarterectomy is self-evident but curiously has been little utilized in practice. The following cases illustrate instances in which ophthalmodynamometric measurements proved of crucial value.

Case 8.—A 51-year-old woman developed throbbing pain in the right eye and eventually a total right ophthalmoplegia. Arteriography disclosed a large right carotid aneurysm in the cavernous sinus. Ophthalmodynamometry revealed a pressure of 150+/81 mm. Hg bilaterally. A Poppen clamp was placed on the right common carotid artery by Dr. Ballantine, and the pressure in the right ophthalmic artery fell to 70/40 mm. Hg while that on the left was 130/55. Five days later the patient again complained of pain in the right eye. Ophthalmodynamometry revealed a pressure of 133/52 mm. Hg in the left eye, but ophthalmic artery pressure on the right had risen to 94/50 mm. Hg. Inspection of the dressing showed that the clamp had become loose, and on reclosure the right ophthalmic artery pressure dropped to 75/43 mm. Hg within a few minutes. A tantalum band was later placed around the carotid artery, and at that procedure internal carotid arterial pressures were measured by direct manometry in the operating room while ophthalmodynamometry was performed simultaneously. Simultaneous measurements revealed the internal carotid pressure to be 80/60 mm. Hg, and ophthalmodynamometry disclosed a pressure of 81/55 mm. Hg. Five days later ophthalmic artery pressures were 67/38 mm. Hg in the right eye and 142/64 in the left. The patient improved symptomatically.

Case 9.—A 57-year-old woman suddenly developed a left-sided hemiplegia and left homonymous hemianopsia. Arteriography revealed an aneurysm of the right internal carotid artery above the bifurcation. Because of progressive worsening of symptoms a Poppen clamp was placed on the right common carotid artery by Dr. Ballantine. Mean carotid pressure by direct manometry at surgery was 62 mm. Hg, and ophthalmodynamometry two hours later revealed the pressure to be 68/50 mm. Hg in that eye. On the first postoperative day, the patient developed further paralysis of the left leg and the clamp was opened. Successive ophthalmodynamometric readings after operation were as follows: two hours, 68/50 and 150+/75 mm. Hg in the right and left eyes respectively; one day, 65/30 and 150+/52; two days (when clamp was opened), 60/30 and 130/60; three days, 62/35 and 140/59; and four days, 87/41 and 150+/65. With rise in general blood pressure and signs of cerebral edema the patient became less responsive and died. Autopsy permission was not obtained.

Comment.—These two cases illustrate the value of ophthalmodynamometry in carotid ligations. The first patient had a clamp applied to the common carotid artery, and sufficiency of the closure was indicated by ophthalmic artery pressures. A rise in ophthalmic artery pressure was noted along with recurrence of pain in the eye and led to awareness of incomplete closure of the clamp. The second patient showed a gross inequality of the arterial pressures in the two eyes, suggesting adequate occlusion, but this persisted after removal of the clamp.

Case 10.—A 51-year-old man suddenly developed a right-sided hemiplegia and global aphasia. Ophthalmic arterial diastolic pressures were 69 mm. Hg in the right eye and less than 20 mm. Hg in the left eye (*minimal scale reading*). Arteriography revealed a left internal carotid thrombosis just above the bifurcation. A left endarterectomy was performed by Dr. Kjellberg seven hours after onset of the stroke, and the next day the ophthalmic artery pressures were 150+/90 mm. Hg in both eyes. Six days later the ophthalmic artery pressures were still 134/65 mm. Hg and repeat arteriography confirmed the patency of both carotids. Twenty-two days after operation pressures were 150+/67 mm. Hg on the right and 148/71 on the left. Later, after anticoagulant therapy was discontinued, the course was complicated by the development of cortical blindness attributed to bilateral posterior cerebral artery occlusion. The ophthalmic artery pressures remained equal, and no other neurological signs consistent with carotid disease developed.

Case 11.—A 72-year-old man developed a left-sided hemiparesis and was shown by arteriography to have a right internal carotid artery thrombosis. Initial ophthalmodynamometric measurements with the patient in the supine position revealed pressure in the right eye to be 103/36 mm. Hg and in the left eye 130/55. Endarterectomy was performed by Dr. Kjellberg, and three days later the ophthalmic artery pressures were 80/34 mm. Hg on the right and 95/36 on the left. However, a cherry red spot gradually developed at the right macula, and 14 days after operation ophthalmodynamometry revealed the pressure in the right eye to be 70/42 mm. Hg and in the left eye 87/45. Repeat arteriography revealed the right carotid to be occluded.

Comment.—Cases 10 and 11 illustrate evaluation of endarterectomy. In case 10 a satisfactory restoration of equal ophthalmic artery pressures occurred and correlated well with an arteriographically patent artery. The patient in case 11, on the other hand, showed a persistently lower pressure on the operated side, and this, likewise, was consistent with the arteriographic demonstration of persistent occlusion of the carotid artery.

Summary and Conclusions

Ophthalmodynamometry is a clinical method for *determination of ophthalmic arterial pressures in* a rapid, safe fashion. Its usefulness as a diagnostic method for internal carotid arterial insufficiency appears well established. The determination and *comparison of the ophthalmic artery pressures* with the patient in the supine and the standing positions appears to enhance the diagnostic sensitivity of this test. Indications for ophthalmodynamometry are (1) clinical evaluation of cerebrovascular disease (strokes due to carotid artery occlusion, pulseless disease, aortic arch syndrome), (2) study of any case of amaurosis fugax, (3) evaluation of carotid ligations and endarterectomies, (4) evaluation of response to anticoagulant therapy in carotid disease, and (5) routine examination prior to arteriography.

Use of ophthalmodynamometry in study of cerebrovascular disease has given rise to these observations: The posture test appears to facilitate the diagnosis of carotid insufficiency in some cases. Systolic pressures should be obtained in patients in whom no unequivocal difference in diastolic values exists. Ophthalmic artery pressure in carotid artery disease may rise with anticoagulant therapy. Difficulty in obtaining reproducible values on ophthalmodynamometry should suggest auricular fibrillation or other arrhythmia. The technique is of definite clinical value in following carotid ligations and the effectiveness of endarterectomy.

CLINICAL EVALUATION OF METHYLPHENIDATE (RITALIN) HYDROCHLORIDE IN THE NEWBORN INFANT

Arnold S. Gale, M.D., Cleveland

Methylphenidate (Ritalin) hydrochloride is a mild central nervous system stimulant which has been administered to counteract drug-induced as well as other central nervous system depression.[1] It has been shown to be effective in shortening recovery time after light thiopental sodium–nitrous oxide anesthesia.[1k] In my experience, patients who have been depressed to a point short of unresponsiveness to verbal commands generally improve, often dramatically, after the intravenous administration of methylphenidate. More deeply depressed patients usually show some sign of lightening but not enough to awaken the patient in a short time. Respiratory minute volume was increased an average of 65% in 14 patients.

The optimum dose was found to be 0.1-0.2 mg. per pound of body weight in the anesthesia recovery time study. Very high doses were found to be less effective than the optimum.

Side-effects were limited to transient mild raising of the blood pressure and momentary nausea or retching in the clinical dose range. A dose 10 times the optimum was followed by marked tachycardia in one patient, but no tremors or convulsions were noted even after such huge doses.

Methods of Study

In order to reduce the depression of infants delivered of moderately and heavily medicated mothers, methylphenidate was administered intramuscularly in doses of 15-30 mg. to a group of 54 mothers. An attempt was made to administer it 30 to 60 minutes before delivery, but the actual time of administration varied between 3 and 498 minutes before delivery. A placebo solution was administered to a similar group of 27 patients. The principal cooperating obstetrician was impressed by the clinical improvement of the infants and complained that methylphenidate was losing its effectiveness when the placebo was substituted without his knowledge. The infants were evaluated by myself and other resident and staff anesthesiologists with respect to the onset of spontaneous and adequate respiration and of spontaneous and "good" crying (2 on the Apgar[2] scale of 0 to 2). The times for all these end-points were shorter for the methylphenidate-treated group. However, because of the wide individual variation in the medication—even though the group averages were similar—the data from these small groups were not considered suitable for rigid statistical evaluation. The study was discontinued because it was found much more practical to administer methylphenidate to the newborn infant directly, if he seemed depressed.

Methylphenidate (Ritalin) hydrochloride was administered intramuscularly to a group of 54 moderately or heavily medicated obstetric patients. It effectively reduced the depression of their newborn infants. The optimum dose appeared to be 0.1 to 0.2 mg. per pound (0.045 to 0.090 mg. per kilogram) of body weight. Subsequently it was found more practical to administer the drug intramuscularly directly to depressed infants after performing adequate oxygenation. Methylphenidate is not a substitute for oxygenation. Methylphenidate produced a marked increase in respiratory activity within 1 or 2 minutes and increased crying and body activity within 5 to 10 minutes. If the depression recurs, repeated administration of the drug is suggested. The drug produced mild side-effects, consisting in mild rise of the blood pressure and momentary nausea or retching. Methylphenidate may be used to supplement a specific narcotic antagonist, if the depression is attributable to a narcotic or to a combination of a narcotic and other depressants.

Methylphenidate, 1 mg. per 5 lb. (2.3 kg.) of body weight, was administered intramuscularly to the apparently depressed newborn infant after adequate oxygenation, with or without intermittent positive-pressure as indicated. A group of 18 babies were treated originally.

Results

Although the improvement generally noted after the administration of methylphenidate could not be attributed definitely to this agent in any given case, it was so marked and so consistent there was little doubt in my mind that the methylphenidate was effective. Within a surprisingly short time (one to two minutes), there was generally a marked increase in respiratory activity. Within 5 to 10 minutes there was usually increased crying and bodily activity, which reached a maximum in 15 to 20 minutes. Although the duration of action of methylphenidate seemed to be about three hours, the drug-depressed babies did not regress except for a return to more normal bodily activity. If such regression were to occur, the methylphenidate administration could be repeated at suitable intervals.

From Mount Sinai Hospital.

The apparently beneficial results of the methylphenidate administration were promising enough to warrant its continuation as routine treatment of depressed newborn infants in the delivery suite as well as in the nursery, especially for premature infants, even though drugs were not necessarily involved in the depression.

It should be stressed that no drug is a substitute for adequate oxygenation, which should be accomplished first. It should also be noted that a specific narcotic antagonist should be administered when the depression is due to a narcotic. However, even in these cases methylphenidate may be useful, as it seems to supplement the antinarcotic activity of the specific antagonists. When there is doubt or when other depressants are also involved, methylphenidate would be indicated in addition to the specific drug. The safety and effectiveness of methylphenidate administered to the depressed newborn infant warrants its further clinical trial.

Summary

Methylphenidate (Ritalin) hydrochloride is a mild central nervous system stimulant which appears to be free from serious side-effects. It is apparently effective in reducing depression of the newborn infant when administered to the mother, but it has been found more practical to administer it to the depressed infant directly. It appears to be safe and effective when so administered and warrants further clinical trial.

1800 E. 105th St. (6).

The methylphenidate hydrochloride used in this study was supplied as Ritalin hydrochloride by Ciba Pharmaceutical Products Inc., Summit, N. J.

CLINICAL NOTES

REACTIONS TO ORALLY ADMINISTERED POISON IVY EXTRACT

William B. Swarts, M.D.
and
Thomas A. Rourke, M.D., Greenwich, Conn.

An orally administered poison ivy extract, Aqua Ivy, AP, is now being sold without prescription; each tablet contains 0.6 mg. of alum-precipitated poison ivy complex. Mass immunization of persons of varying sensitivities to poison ivy extract, without medical supervision, is hazardous, as shown by the following case summaries.

A female, aged 14, took one tablet of Aqua Ivy, AP as directed, every other day, on April 3, 5, and 7, 1958. The patient, when seen on April 9, had swelling of right wrist and elbow joints, associated with a purpuric rash of the arms and the chest. This girl, for a number of years, has suffered from severe poison ivy attacks necessitating bed rest and a physician's attendance.

The members of a family (consisting of husband and wife, both aged 41, and their sons, aged 15 and 11) each took one tablet of Aqua Ivy, AP on March 18, 20, and 22, 1958. The husband and wife both had severe generalized pruritus with headache lasting for one week. The reaction in the 11-year-old boy was essentially the same as in his parents. The 15-year-old boy started itching after the second dose, and bullae over a centimeter in diameter developed on his fingers and persisted for one week. All members of this family had a history of poison ivy sensitivity.

No other drug or infection was a factor in these four cases that would account for the symptoms after taking the poison ivy extract tablets.

Comment

The joint swelling and purpuric eruption in the first case give evidence of deep tissue and vascular reactions. Vital organs can be involved in such reactions; kidney damage has been reported.[1] The persistent headache and pruritus in adults taking the Aqua Ivy, AP is indicative of probable vascular involvement in the central nervous system.

Conclusions

Persons with a history of marked sensitivity to poison ivy should receive immunization procedures individualized for the patient. Mass desensitization procedures, without medical supervision, are dangerous.

Warwick Towers (Dr. Swarts).

TREATMENT OF ACUTE GOUT WITH INJECTION OF COLCHICINE

Lynn P. Carmichael, M.D., Miami, Fla.

Colchicine is one of the oldest and most specific pharmaceuticals available. While newer agents such as the corticosteroids, phenylbutazone, and probenecid are valuable in the treatment of gouty arthritis, colchicine remains the most useful drug in the treatment of this disorder. Although colchicine is a remarkably safe drug, its oral administration frequently results in nausea, vomiting, and diarrhea. These manifestations act as a limiting factor and may obviate the full effectiveness of the drug. Colchicine injection is now available for intravenous administration. When the drug is given by this method, and the indicated dosage is not exceeded, gastrointestinal side-effects are rarely encountered and the response is more rapid than that obtained with the oral method. Cautious intravenous administration is also a valuable diagnostic procedure.

Report of Cases

CASE 1.—An obese 43-year-old man developed pain and swelling of the left knee eight days after an automobile accident. There was no history of trauma to the involved region. The patient denied any previous arthralgia or skeletal disease. The patient was seen the day after the onset of pain, at which time his temperature was 101 F (38.3 C) orally. The entire left knee was swollen and of a dusky red appearance. The erythema was most marked over and about the patella, which was exquisitely tender. All motion of the left knee was obviously painful. The patient was hospitalized, and the following laboratory results obtained: white blood cell count, 12,200 per cubic millimeter, with neutrophils predominating; sedimentation rate, 15 mm. per hour; uric acid, 7.35 mg. %. Shortly after admission the patient was given 2 mg. (4 cc.) of colchicine intravenously; 12 hours later he received another dose of 1 mg. (2 cc.). By this time there was moderate subjective improvement, and the patient was afebrile. Objective findings were the same. Eight hours later he again received 1 mg. (2 cc.). By this time there was marked symptomatic relief but little change in physical findings. The patient was then given 1 mg. of colchicine and 1 Gm. of probenecid to be taken orally twice daily. The patient's condition gradually improved, and he was discharged ambulant 12 days after admission.

CASE 2.—A 59-year-old man was seen at home with pain and swelling of the right knee of two days' duration. The only significant item in the patient's history was a shrapnel wound of the right knee sustained in World War I. The entire joint was quite tender, dusky red in color, warm, with marked effusion. He was hospitalized the day he was first seen. A roentgenogram taken on admission was reported as showing no significant bony abnormalities but considerable soft-tissue swelling around the joint. There was a metallic foreign body on the medial aspect of the knee joint. Urinalysis and complete blood count gave normal results. The sedimentation rate was 39 mm. per hour; uric acid level, 2.8 mg. %. An arthrocentesis was performed, and 80 cc. of straw-colored mucoid fluid was obtained. The test for uric acid gave a negative result. There were 5,000 white blood cells per cubic millimeter. The paracentesis afforded the patient considerable relief. After this he was given an injection of 2 mg. (4 cc.) of colchicine intravenously; he received 1 mg. (2 cc.) intravenously on two occasions the following day. By the time of the third injection the pain had subsided considerably; the knee remained red and tender, however, with slight recurrence of the effusion. He was then given maintenance therapy with colchicine and probenecid taken orally twice daily. His condition slowly improved, and he was discharged 10 days later, on crutches with partial weight-bearing. He had completely recovered and was ambulant four weeks after the onset of pain.

Clinical Instructor in General Practice, University of Miami School of Medicine.

Case 3.—A 50-year-old man was seen in the office because of swelling of the left ring finger. He had an eight-year history of recurrent migratory arthralgia and had been treated with aspirin and corticosteroids. The episodes usually lasted 5 to 10 days. To his knowledge, the diagnosis of gout had never been made. The patient was afebrile. The left third finger was swollen and red about the proximal interphalangeal joint, and there was considerable tenderness. There were no other deformities noted, and no tophi were found. The blood uric acid level was 6.5 mg. %. The patient was seen the next morning in the office and given an injection of 2 mg. (4 cc.) of colchicine intravenously. He returned the same afternoon and was given another dose of 1 mg. (2 cc.). This was repeated the morning of the third day. By that time the pain, swelling, and redness of the finger had subsided, and the only complaint was a slight stiffness. He was placed on maintenance therapy with colchicine and probenecid by mouth and continued to do well until his death from a myocardial infarction several weeks later.

Case 4.—A 55-year-old obese alcoholic man was seen in the office with a one-week history of pain and swelling of the left foot. There was no history of injury or previous joint disease. The dorsum of the right foot was swollen, red, warm, and tender; the white blood cell and differential blood counts were normal; sedimentation rate was 21 mm. per hour; uric acid, 2.75 mg.%. The patient was given an injection of 2 mg. (4 cc.) of colchicine intravenously. Later in the afternoon of the same day he received another dose of 1 mg. (2 cc.) intravenously. At that time there was slight subjective improvement. This dosage was repeated the next morning, at which time the patient was asymptomatic. The physical findings remained essentially unchanged. Therapy was started with probenecid and colchicine by mouth, and when the patient was seen two weeks later the foot appeared normal.

These four cases illustrate the diagnostic and therapeutic advantages of intravenously administered colchicine. In two of the above cases the uric acid level was within normal limits, and the intravenous injection of colchicine confirmed the clinical impression of gouty arthritis. None of the patients experienced any undesirable gastrointestinal disturbances. One individual had a mild thrombophlebitis of the vein in the left antecubital space, which subsided rapidly. No other toxic effects were noted.

Summary

Intravenous administration of colchicine is a rapid, safe, and uncomplicated method of treating acute gouty arthritis. It is of special value as a diagnostic procedure in those cases where the diagnosis of gout is doubtful, because of its rapid action and freedom from the nausea, vomiting, and diarrhea often found with oral administration.

COUNCIL ON DRUGS

Report to the Council

The Council has authorized publication of the following paper, which was presented by Dr. Warren H. Cole as part of a symposium-panel discussion held in Washington, D. C., Sept. 25, 1958, on The Use and Abuse of Adrenal Steroids. This is the fifth paper in the series, the first four of which appeared in The Journal *on June 20 and 27 and July 4 and 11, 1959, pp. 952, 1063, 1179, and 1311.*

H. D. Kautz, M.D., *Secretary.*

STEROID THERAPY IN SURGICAL PATIENTS

John H. Schneewind, M.D.
and
Warren H. Cole, M.D., Chicago

The increased use of steroids in the treatment of general medical problems has been paralleled to a moderate extent by the increased use of these drugs for surgical patients in the preoperative and postoperative periods, as well as during operative procedures. In our experience, there are three situations in which steroid therapy is indicated. The first is in acute severe injury or illness in which acute adrenal insufficiency is suspected because of a significant fall in blood pressure not explained by blood loss or coronary disease. In many instances it is difficult to be sure that these patients have a true adrenal insufficiency, and, if they recover, it is not always clear whether steroid therapy was responsible. Admittedly, this is not a very common situation. The second category of patients in whom steroid therapy is indicated are those who have been receiving steroid medication for arthritis or colitis for weeks

---

From the Department of Surgery, Research and Educational Hospitals, University of Illinois.

or months. It is necessary to assume that the patient may have some degree of adrenal suppression and that cortisone (Cortisone, Cortogen, Cortone) acetate and hydrocortisone (Cortef, Cortril, Hycortole, Hydrocortone) will be needed in the immediate operative period to prevent an acute adrenal insufficiency. A third type of patient in whom steroids may be useful is the chronically ill, malnourished person who has no desire for food. Some of these patients regain their appetite, eat well, and have a general feeling of well-being after administration of corticotropin (ACTH, Acthar, Corticotropin, Cortrophin). Frequently, a significant weight gain, with positive nitrogen balance, seems to improve their ability to withstand the stress of operation.

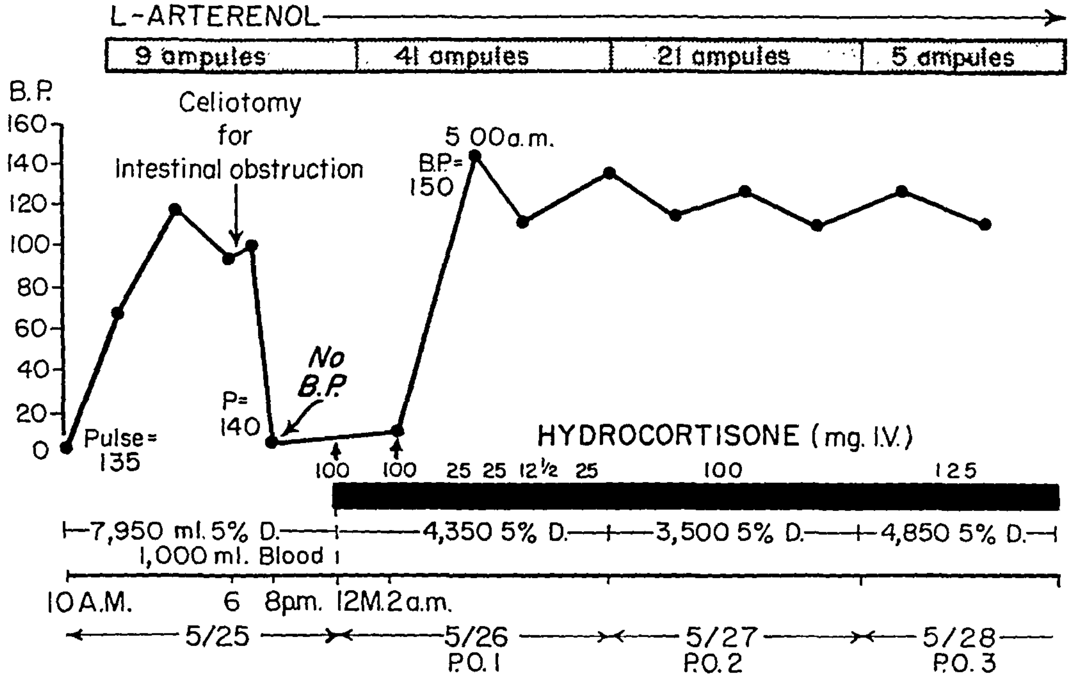

Fig. 1.—Patient with prolonged severe hypotension treated with levarterenol bitartrate and hydrocortisone sodium succinate.

Adrenal Insufficiency due to Acute Illness or Injury

Significant hypotension which cannot be explained by acute blood loss, myocardial infarction, anesthesia, drugs, or electrolyte imbalance should suggest the possibility of an acute adrenal insufficiency. This is especially true if the blood pressure does not respond promptly to blood transfusions or vasopressors.

Adams and Siderius[1] have reported on five patients with postoperative shock in whom they felt the diagnosis of adrenal insufficiency was justified. One patient had persistent hypotension and tachycardia after removal of a hydronephrotic kidney. In the immediate postoperative period the hypotension became severe, despite adequate blood, fluid, and electrolyte therapy. Levarterenol (Levophed) bitartrate was given continuously but was ineffective. On the third postoperative day hydrocortisone sodium succinate (Solu-Cortef) was given intravenously, and the blood pressure rose sharply and gradually stabilized. The patient received a total of 250 mg. on the third day and 200 mg. on the fourth day. No levarterenol was required. The patient recovered and was discharged on the 14th postoperative day. Adams and Siderius suggest that an increase in capillary resistance and potentiation of the effect of vasoconstrictors on blood vessels may be factors in the blood pressure response to adrenal corticosteroids. However, they warn that epileptic seizures or psychotic reactions may be precipitated by administration of steroids.

Howland and associates[2] reviewed the statistics covering a one-year period at the Memorial Center for Cancer and Allied Diseases and reported that 25 cases, or approximately 1 out of every 300 patients subjected to operation, exhibited some form of adrenal cortical insufficiency. They reported in detail on seven cases. One patient with a bronzed skin was thought to have had a previously unrecognized adrenal cortical hypofunction; one patient had been taking cortisone for several months prior to operation, and one patient had had bilateral adrenalectomy and oophorectomy for metastatic breast cancer. The other patients had no obvious reason for adrenal insufficiency. All of the patients exhibited persistent hypotension and failed to respond to adequate blood replacement and vasoconstrictors. Respiratory depression and prolonged reaction time after anesthesia also occurred. All seven of the patients reacted favorably and rapidly after intravenous administration of soluble hydrocortisone. Howland and colleagues[2] believe that the basic physiological disturbance was a deficiency of adrenal cortical secretion.

Hayes[3] has studied the endocrine response to stress of normal patients and of patients with limited adrenocortical reserve. Most of the patients were subjected preoperatively to either the epinephrine-eosinophil response or the corticotropin-eosinophil (Thorn) test. Ordinarily, increased adrenal cortical output is reflected in a decrease in the numbers of eosinophils and lymphocytes in the blood. Hayes believes that an elevated eosinophil count during stress is direct evidence of an insufficient supply of adrenocortical hormone. If the patient is in shock that is unresponsive to adequate blood replacement and if the eosinophil count is not at the anticipated low level, a condition of temporary adrenocortical insufficiency is present and should be treated with steroids administered intravenously.

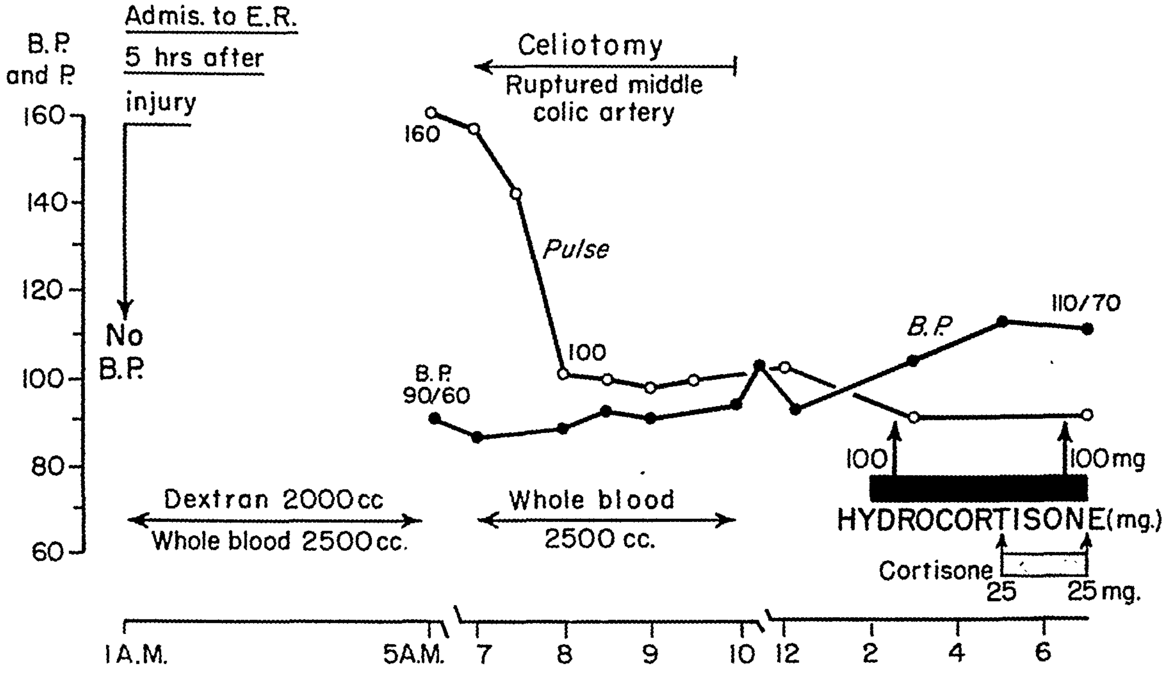

Fig. 2.—Recovery record in patient after massive hemorrhage due to blunt trauma. Hydrocortisone given intravenously seemed of benefit in stabilizing blood pressure and improving pulse.

An example of our experience with this type of problem may be illustrated by the case of a 47-year-old woman who was admitted to the hospital because of cramping abdominal pain, distention, and vomiting for four days (fig. 1). She was obviously acutely ill, with a distended abdomen and only occasional bowel sounds. Her blood pressure was unobtainable. Although the patient's sensorium was depressed, she was able to answer questions and give a coherent history. Soon after admission a Levin tube was passed, and immediately a great deal of gastric content was returned. Fluids containing levarterenol were given intravenously, but it was not until four hours after admission that a blood pressure reading was obtained. Eight hours after admission the patient was taken to the operating room. Celiotomy confirmed the diagnosis of obstruction of the small intestine, which was secondary to adhesions in the pelvis due to previous operations. The patient tolerated the operation fairly well, but soon after reaching the recovery room the blood pressure was again unobtainable. Despite the fact that levarterenol was given continually after the operation, the blood pressure continued to be unobtainable. At midnight, four hours after operation, 100 mg. of hydrocortisone sodium succinate was administered intravenously, and another 100 mg. was given about two hours later. At the same time, the quantity of levarterenol administered was increased. At 2 a. m. the blood pressure was still unobtainable. At 5 a. m., approximately five hours after administration of the first dose of hydrocortisone sodium succinate, the blood pressure was 150/80 mm. Hg, and, although it fluctuated a good deal, it remained at satisfactory levels. An additional 87.5 mg. of hydrocortisone sodium succinate was administered on the first postoperative day, making a total of 287.5 mg. of that drug. The patient received a total of 82 mg. of levarterenol during this period. On the second postoperative day, 100 mg. of hydrocortisone sodium succinate was given, and it was possible to maintain the blood pressure with about half of the amount of levarterenol previously required. On the third postoperative day, the patient received 125 mg. of hydrocortisone sodium succinate and 10 mg. of levarterenol. On the fourth and fifth postoperative days, the patient received 80 and 45 mg. of hydrocortisone sodium succinate, respectively, but no levarterenol was required (fig. 1).

The patient's postoperative course was uncomplicated, except for a severe slough of the skin on the lower half of the right leg at the site of administration of the levarterenol. This area was treated in routine fashion and eventually was covered with split skin grafts.

Another example of temporary adrenocortical insufficiency is that of a 51-year-old man who was admitted to the hospital five hours after an automobile accident in which he had been struck in the abdomen by the steering wheel (fig. 2). On admission to the emergency service, no pulse or blood pressure was obtainable. After administration of two liters of dextran (Dextran, Expandex, Gentran) and 2,500 cc. of whole blood, the blood pressure was 90/60 mm. Hg and the pulse rate 160 per minute. The patient was taken to the operating room, and a celiotomy revealed a ruptured middle colic artery which was spurting vigorously. There was a great deal of blood in the peritoneal cavity, marked cyanosis of the transverse colon, and extravasated blood in the mesocolon. The patient received an additional 2,500 cc. of whole blood during the operation. His pulse rate gradually subsided to about 100; however, the blood pressure remained at 90 mm. Hg. The middle colic artery was ligated, and a transverse colostomy was performed.

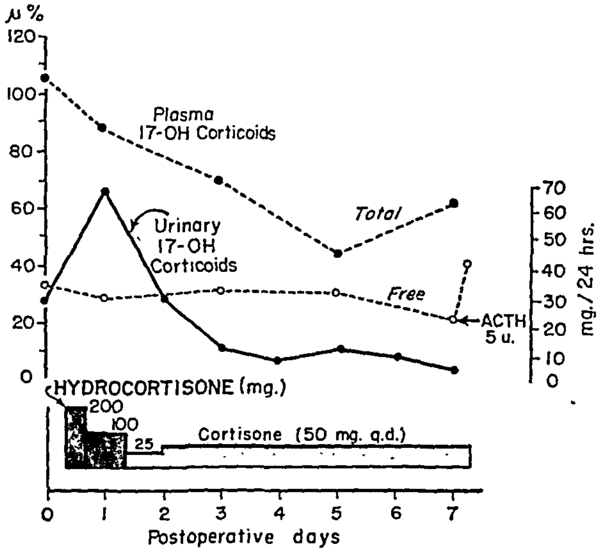

Fig. 3.—Steroid output of patient with massive hemorrhage due to blunt trauma.

Although the patient tolerated the procedure moderately well, his blood pressure remained low, his skin was cool, and his peripheral pulse was of poor quality. Four hours after the end of the operation, 100 mg. of hydrocortisone sodium succinate was added to the intravenous fluids (fig. 2). During the next two hours the patient's systolic pressure rose, and the pulse slowed to 80 per minute. The patient received a total of 300 mg. of soluble hydrocortisone intravenously during the remainder of the first postoperative day.

The patient developed a spiking fever due to pneumonitis three days after operation. The fever gradually subsided, however, and the patient's postoperative course otherwise was fairly good. He was readmitted to the hospital a month later for closure of his colostomy, which was tolerated without incident. This patient's steroid output during the immediate postoperative period was studied, and a graphic representation of our findings is shown in figure 3. The initial determination of plasma corticosteroids was made on blood drawn during operation. The elevated total plasma corticosteroid level of 106 mcg. per 100 cc. is probably related to oliguria due to the long period of hypotension. The free plasma corticosteroids, on the other hand, were at normal levels throughout the immediate postoperative period. The subsequent values for the total plasma and urinary corticosteroids reflected the intravenous administration of hydrocortisone sodium succinate. On the seventh postoperative day, a 5-unit test dose of corticotropin was administered, and one hour later the patient's free plasma corticosteroids had risen from 20 to 38 mcg. per 100 cc. This is consistent perhaps with an active adrenal reserve and ability to respond to stressful stimuli.

Preparation of Patients on Prolonged Steroid Therapy for Operation

It is well known that prolonged steroid therapy will produce adrenal atrophy and that patients with adrenal cortical insufficiency tolerate the stress of operation when given adequate doses of steroids. The administration of corticosteroids should be continued during the operative period and during the immediate postoperative period. Schwartz and associates[4] studied the records of 19 patients with adrenal cortical insufficiency subjected to operation. Three deaths occurred in this series, and none of these three patients had received specific hormone therapy prior to or during operation. Hypotension occurred in 14 patients during anesthesia or in the postoperative period, and it occurred with the same frequency regardless of the anesthetic agent used. They feel that agents which may produce significant hypotension are inadvisable and warn of the necessity for an alert watch for hemorrhage and excessive trauma during operation.

In a review of the problem of administration of anesthetics to patients who have been receiving steroids, Lundy[5] was one of the first to emphasize that, since prolonged administration of cortisone may result in atrophy of the adrenal cortex, patients who have been receiving this medicament must be properly prepared for operation. He feels that the anesthesiologist should be able to recognize the atypical picture of shock which may occur during anesthesia and operation and should be prepared to treat this with appropriate steroid therapy.

In a comprehensive review of the problems of postoperative adrenal insufficiency, Root[6] cites several reports concerning adrenal insufficiency produced by administration of cortisone. One study showed a diminution of the average weight of 46 adrenal glands at autopsy in patients who had been given cortisone, as compared with a control series of patients who had not been receiving cortisone. The author also points out that circulatory collapse not related to blood loss and not responding well to transfusions and vasopressors may occur not only during or shortly after operation but up to one or two days later. He states that usually there is an unexpected degree of mental confusion which may be followed by disorientation and coma. Subnormal temperature and profuse sweating have also been noted.

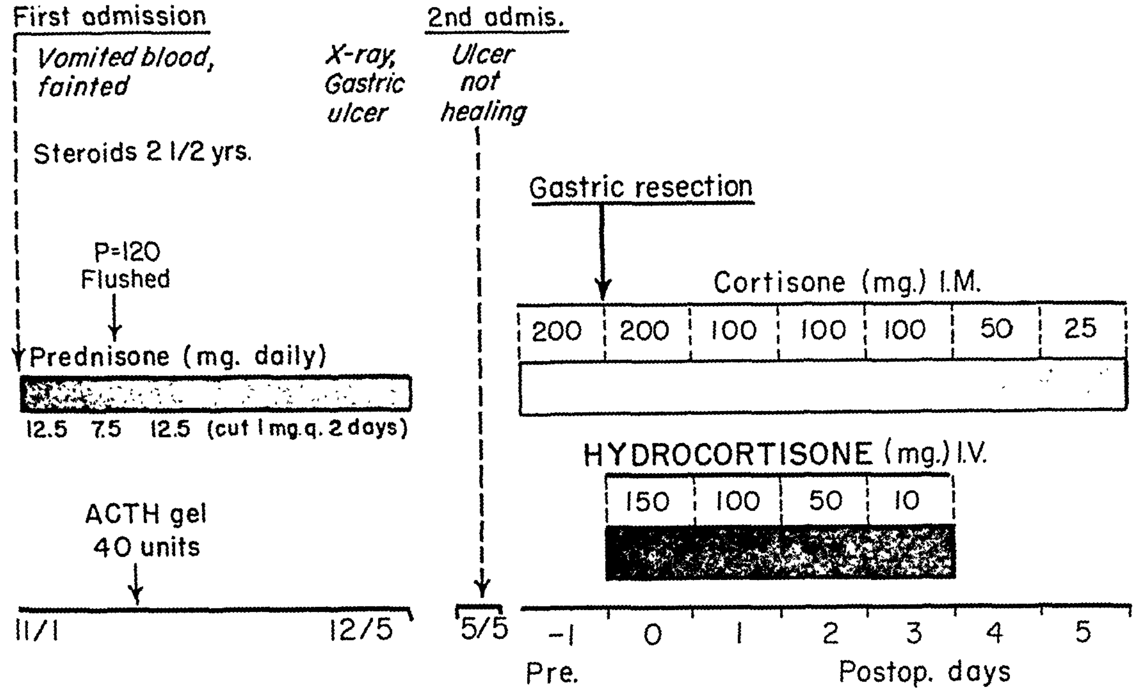

Fig. 4.—Steroid management of patient operated on for gastric ulcer. Administration of steroids was required because patient had been receiving them for arthritis for two and one-half years.

Engleman and associates[7] attempted to determine the degree of cortical suppression after steroid therapy by studying 19 patients who had been receiving maintenance doses of cortisone for 12 to 26 months. These patients showed a response to stimulation on the third to sixth day of corticotropin therapy, whereas control patients responded on the first or second day. They conclude that, although adrenal function may be suppressed by long-term cortisone therapy, the suppression is usually reversible. It must be remembered, however, that a markedly increased demand, as in a patient undergoing operation, might not be covered by adequate adrenal function. In general, it is probably a safe rule that any patient who has received steroid therapy for five days or more during the year preceding operation should receive prophylactic treatment to prevent adrenal cortical insufficiency during an operative procedure.

The problem of management of a patient undergoing steroid therapy who experiences a sudden onset of upper gastrointestinal hemorrhage is presented by the case of a 43-year-old woman who entered the hospital because of hematemesis on the day prior to admission (fig. 4). This patient had suffered from rheumatoid arthritis for 19 years and had been receiving cortisone for approximately 2½ years prior to admission. The cortisone therapy had been changed recently to prednisone (Deltasone, Deltra, Meticorten, Paracort), 12.5 mg. daily. On the day before admission the patient had been doing her housework when suddenly she became dizzy and fainted. On regaining consciousness she found that she had vomited bright red blood. Roentgenographic studies revealed evidence of arthritic changes, most marked in the hands, and a large ulcer-crater deformity along the greater curvature of the midantrum. The patient was placed on an ulcer regimen, and the prednisone dose was reduced to 7.5 mg. Because of tachycardia, flushing of the face, extreme weakness, and thirst, the amount of prednisone was increased to the original dose of 12.5 mg. It was then gradually reduced by 1 mg. every two days and finally discontinued completely. The patient subsequently developed bilateral conjunctivitis which responded to an ophthalmic preparation of hydrocortisone. Although repeated upper gastrointestinal x-rays showed some healing of the ulcer, complete healing had not yet occurred approximately six months after the initial episode of hematemesis. At this time, it was felt that celiotomy was indicated.

The patient was prepared for operation and received 200 mg. of cortisone acetate intramuscularly the day prior to and again on the day of operation (fig. 4). The patient received 100 mg. of cortisone acetate daily on the first, second, and third postoperative days, 50 mg. on the fourth, and 25 mg. on the fifth postoperative day. The patient also received hydrocortisone sodium succinate intravenously on the day of operation and on the first, second, and third postoperative days. A gastric resection was performed, which the patient tolerated very well. Her postoperative course was uneventful and on discharge she was receiving aspirin for her arthritis but was not on any steroid medication.

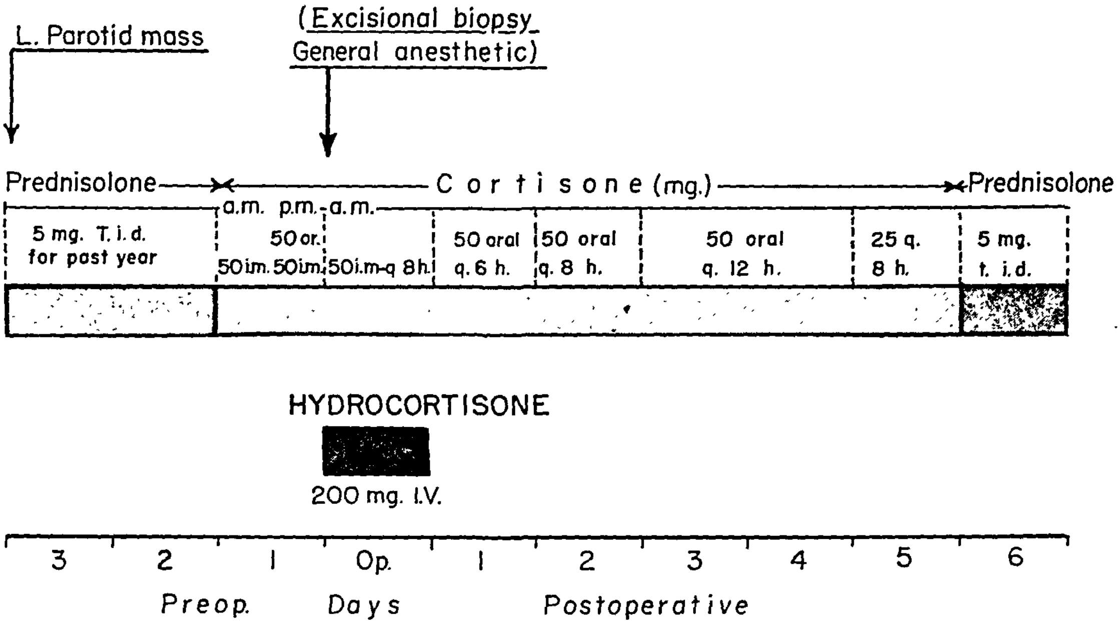

Fig. 5.—Steroid management of female patient during operative period. Patient had been receiving prednisolone for one year prior to admission.

Another example of a strong indication for steroid therapy during the immediate operative period occurred in a woman, aged 57, who had been receiving prednisolone (Delta Cortef, Hydeltra, Meticortelone, Paracortol) for the past year. She entered the hospital because of a mass in the left preauricular area which had been increasing in size during the month prior to admission. Approximately 18 months prior to this admission, the patient had had a laminectomy. At this operation a lymphoblastoma covering the dura from T-2 to T-6 was found. The patient had received radiation therapy and a course of nitrogen mustard postoperatively. During the year prior to admission, she had been receiving 15 mg. of prednisolone daily. Physical examination revealed a mass 4 by 4 cm. in the left preauricular area. There also was a 1-cm. mass just posterior to the angle of the mandible. Because of the history of removal of a lymphoblastoma from the spinal canal, it was felt that excisional biopsy of the small lymph gland was indicated. Since the patient was to receive a general anesthetic, her steroid management was planned as for any major operation. The details are shown in figure 5. The prednisolone therapy was continued until the day before operation and then discontinued. On this day the patient received 50 mg. of cortisone acetate intramuscularly in the morning and evening as well as 50 mg. of cortisone acetate orally. On the day of operation the patient received 50 mg. of cortisone acetate intramuscularly before operation and every eight hours thereafter. Prior to induction of anesthesia, 100 mg. of hydrocortisone sodium succinate was added to a liter of 5% dextrose injection and administered intravenously. The patient received soluble hydrocortisone by slow drip throughout the operation and during the rest of the day until midnight, at which time she had received a total of 200 mg. On the first postoperative day the patient was given 50 mg. of cortisone acetate orally every six hours; this was decreased to 50 mg. orally every eight hours on the second postoperative day. The patient received 50 mg. of cortisone acetate every 12 hours on the third and fourth postoperative days and, finally, 25 mg. every 8 hours on the fifth postoperative day. On the sixth day the cortisone therapy was discontinued, and the patient was put back on prednisolone therapy, 5 mg. three times daily (fig. 5).

The patient tolerated the anesthetic and the excisional biopsy without incident and was discharged on the seventh postoperative day. The biopsy specimen revealed metastatic lymphoblastoma, and it was planned to treat her with additional radiotherapy.

Use of Corticotropin in Preoperative Preparation

Treatment of Disease Process.—There is a group of cases in which corticotropin or cortisone may be very effective in improving operability by reducing the serious effects of the disease itself. The two best examples of these diseases or conditions are ulcerative colitis and thrombocytopenic purpura. It is well known that treatment with corticosteroids will cause marked improvement in most patients with these two diseases; it is equally well known that subsequent courses of therapy are decreasingly effective. Accordingly, when patients are acutely ill with either of these two diseases, many clinicians adopt the principle of reducing the manifestations with steroids and then resorting to operation, providing the patient has had ulcerative colitis for at least six months and has other evidence of intractability. Since the benefit of steroid therapy in ulcerative colitis is transient, many clinicians avoid the prolonged use of steroids because, if conservative therapy fails, the surgeon may be compelled to operate, with the patient in a very critical condition. This was the situation with the patient illustrated in figures 6 and 7; the acute manifestation of her disease responded quite well to steroids initially, but, as time passed, cortisone was not effective. Perforations of the colon necessitated an operation, but the patient was in an extremely hazardous condition. She survived the operation but died in the postoperative period. If a colectomy had been performed early, during the initial benefit from steroids, she might have been alive today.

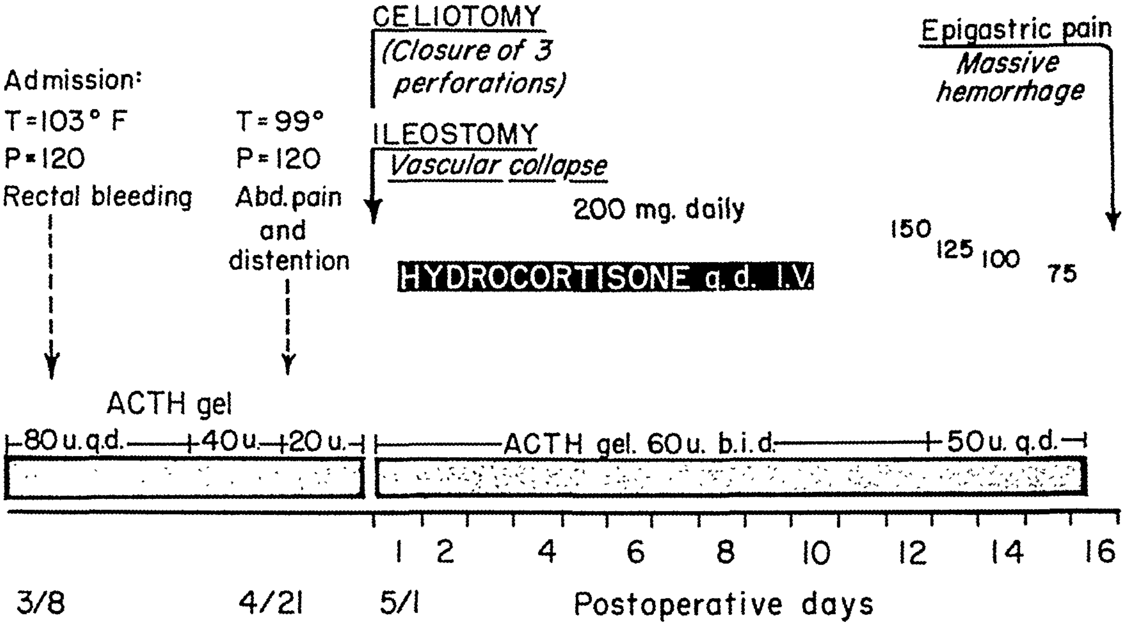

Fig. 6.—Management of patient with severe ulcerative colitis complicated by perforations. Acute vascular collapse during surgery necessitated intravenous administration of hydrocortisone. Drug continued during immediate postoperative period.

Improvement of Appetite and Sense of Well-being.—In selected patients, corticotropin may be of great value in improving appetite, increasing food intake, and producing a feeling of well-being.[8] It is true that some of the weight gain after corticotropin therapy is due to water retention, but the increased food intake often results in elevation of blood protein levels, positive nitrogen balance, and a general improvement of the mental status of the patient about to undergo an operation.

Galante and associates[9] regard corticotropin as an antipyretic and euphorigenic agent. They state that the drug may permit early ambulation, may effect an increase in appetite and sense of well-being, and may decrease the postoperative requirements of narcotics. The authors also discuss the value of corticotropin as an anti-inflammatory agent in such diseases as ulcerative colitis and regional enteritis. They point out that suppression of fever, toxicity, and malaise may result in considerable improvement of the patient prior to operation.

Corticotropin occasionally may be of value in patients with a smoldering rheumatic activity requiring valvuloplasties. The drugs also may be of value in certain allergic or hypersensitive states such as hemolytic anemia and thrombocytopenic purpura, with or without hypersplenism. In the immediate preoperative period, administration of corticotropin may result in a decrease of hemolysis and an increase in the platelet count. Corticotropin and the other steroids also have a place in the treatment of serum sickness and drug and transfusion reactions. In certain cases of nontropical sprue, the adrenal steroids may be effective in producing a remission characterized by improved appetite, increased dietary intake, weight gain, and a decrease in the number, fat content, and watery consistence of the stools.[10]

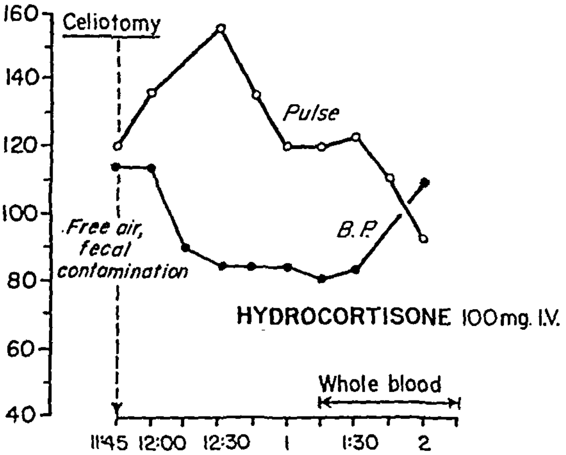

Fig. 7.—Pulse and blood pressure during operative period of patient with severe ulcerative colitis complicated by colon perforations. Hydrocortisone seemed to be of value in elevating blood pressure and reducing pulse rate.

The following history illustrates the use of corticotropin for the purpose of improving appetite and increasing food intake. A 60-year-old woman entered the hospital because of intermittent attacks of pain in the upper part of the abdomen. Approximately four months prior to admission, the patient experienced two attacks of moderately severe pain in the right upper part of the abdomen accompanied by chills and fever. The pain extended to other parts of the abdomen and radiated to the back, and she occasionally suffered from excessive gaseousness and eructation. The patient was fairly well after these attacks, except for a recurrent mild attack approximately two weeks prior to admission. She had lost 11 lb. (5 kg.) during the six months prior to admission. There was no history of jaundice, dark urine, or pale stools. Because of the chills and fever, both an intravenous urogram and a retrograde study were performed. It was the impression of the urologists that the kidneys were normal. A cholecystogram revealed calculi in the gallbladder.

Although the patient claimed she ate well, she failed to gain weight during the first week in the hospital. It was felt that she would benefit from an increased food intake, and corticotropin gel, 80 units daily, was given intramuscularly on the eighth day after admission to the hospital. The patient's weight increased from her admission weight of 115 lb. (52.2 kg.) to a peak of 122 lb. (55.4 kg.) during the six days of corticotropin administration (fig. 8). At this time a cholecystectomy was performed which was tolerated well. The patient's postoperative course was essentially uneventful. After the operation the body weight dropped to a low of 112 lb. (50.9 kg.) on the sixth postoperative day but then began to increase slowly until the patient was discharged. There was a marked increase in 17-hydroxycorticosteroid output by the adrenals after administration of corticotropin prior to operation (fig. 9). The total plasma corticosteroids rose to a peak of 147% and the free corticosteroids to 97%. The total urinary corticosteroids also increased to 82 mg. for 24 hours. These values were recorded after the first two days of steroid therapy.

Another example of the use of corticotropin in improving food intake prior to operation is that of a 64-year-old male who was admitted to the hospital with a history of scleral icterus two and one-half months prior to admission. The patient noted that his stools had become pale and his urine dark. He also complained of epigastric fulness, poor appetite, and easy fatigability. There was a 20-lb. (9-kg.) weight loss during this period. The noteworthy findings on physical examination were the obvious jaundice and a palpable liver and gallbladder. Laboratory studies were consistent with the findings of obstructive jaundice. The patient's alkaline phosphatase and bilirubin levels were elevated; the albumin-globulin ratio was 4.1:2.6; and there was mild anemia.

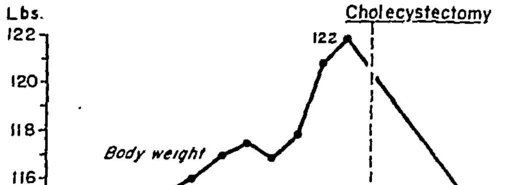

Fig. 8.—Body weight curve after administration of corticotropin in 60-year-old woman.

During the patient's first 10 days in the hospital, he did not eat well because of anorexia and a feeling of fulness in his abdomen after taking small amounts of food and liquid. Because of the failure to gain weight, the patient was started on therapy with 40 units of corticotropin intramuscularly, twice daily. A four-day course of this therapy was given, and the patient's body weight increased from 137 to 143 lb. (62.2 to 65 kg.) (fig. 10). His daily caloric intake increased by approximately 1,200 calories. At operation a large tumor mass consistent with carcinoma was found in the head of the pancreas. A cholecystojejunostomy was performed, with an entero-enterostomy below it. The patient's postoperative course was complicated by severe bronchial pneumonia, with high temperatures. On the eighth postoperative day the pneumonia subsided, and the patient appeared much improved. During this period the icterus had subsided appreciably. The patient's body weight declined during the postoperative period because of the pneumonia but began to increase again after the infection had subsided.

Contraindications and Complications of Steroid Therapy

There are certain contraindications to the routine use of steroid therapy for surgical patients. These include the presence of tuberculosis, malignant hypertension, uremia, psychoses, and the presence of active ulceration in the gastrointestinal tract. Other points which require consideration are the possibility of spread of localized infection, prevention of wound healing, fluid retention, and glycosuria and hypoglycemia due to the anti-insulin effects of corticotropin and cortisone. As a rule, these problems are not encountered during short-term administration of the steroids but become manifest when large doses are administered for periods exceeding seven days.[9]

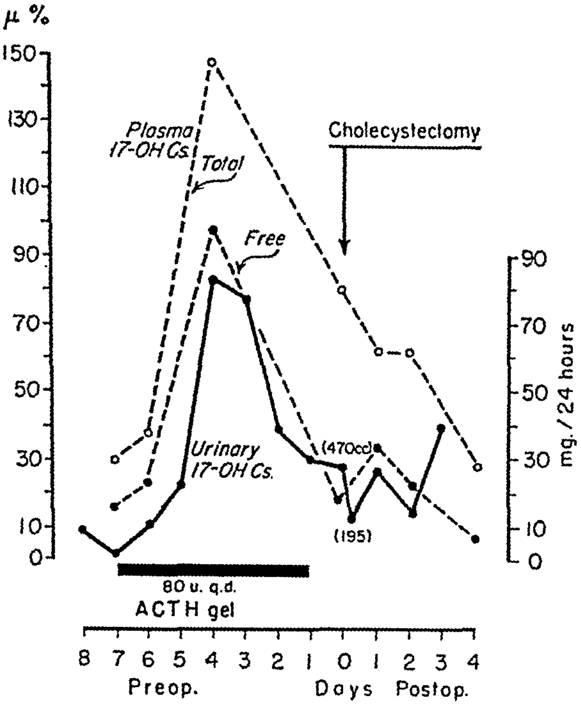

Fig. 9.—Effect of administration of corticotropin on plasma and urinary 17-hydroxycorticosteroids.

In a review of the use of corticotropin and adrenal corticosteroids in diseases of the digestive system, Zetzel[10] states that ulcers rarely develop in patients receiving steroids. He feels that the possibility of the development or even the knowledge of a preexisting peptic ulcer is not an absolute contraindication to an otherwise valid indication for steroids. With respect to perforation of the intestine and hemorrhage, he states that several large series of cases have been reported in which these complications were no more frequent than in control series of patients who were not receiving steroids. However, not all those persons working with steroids would agree with these statements.

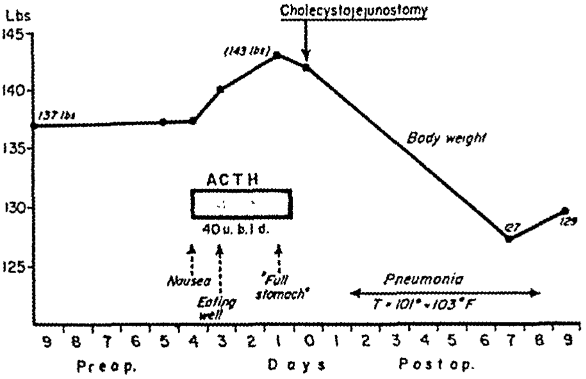

Fig. 10.—Weight gain in patient with obstructive jaundice after administration of corticotropin.

The following complicated case history illustrates several of the problems which may arise in treating surgical patients with steroids. This case history includes intestinal perforation, vascular collapse on the operating table, steroid therapy during operation and in the immediate postoperative period, and, finally, massive hemorrhage, possibly due to steroids. Brief reference has already been made to this patient (fig. 6). She was a woman, aged 32, admitted to the hospital with a history of ulcerative colitis characterized by intermittent episodes of diarrhea, with mucus and blood, for a period of 10 years. Because of exacerbation of the bloody diarrhea, the patient was admitted to the medical service. At this time she was acutely ill, markedly malnourished, and was passing blood through the rectum. Sigmoidoscopy revealed polypoid changes in the rectum. An attempt was made to improve the patient's condition by giving her transfusions, antispasmodics, sedatives, and steroids in the form of corticotropin gel, but the patient continued to lose ground. Approximately one month after admission she experienced a sudden onset of abdominal pain, distention, and tachycardia, probably due to a perforation of the colon (fig. 6). Her condition was so critical it was felt that celiotomy could not be tolerated, and it was elected to treat her with gastrointestinal siphonage and antibiotics, in the hope that the perforated intestine would seal over. This apparently happened; however, 10 days later the patient again had signs and symptoms of a perforation of the colon. Plain films of the abdomen showed a large amount of air under the diaphragm, and it was felt that celiotomy must be undertaken.

At operation a large amount of fecal contamination and three large perforations of the colon were found. The perforations were closed, and an ileostomy was performed. During the operation the patient exhibited signs of an acute vascular collapse; however, the blood pressure improved after administration of blood and hydrocortisone sodium succinate (fig. 7). The patient continued to be in very critical condition after the operation. She received hydrocortisone, corticotropin, a liter of protein hydrolysate, and 500 cc. of cottonseed oil (Lipomul I. V.) daily. Several units of human serum albumin and whole blood were given. She gradually improved until, on the seventh day after operation, she was able to take liquids by mouth. Two weeks after the operation the patient suddenly developed a spiking fever associated with a shaking chill, and soon afterward dark blood appeared from the ileostomy. A Levin tube was inserted, and approximately 200 cc. of dark blood was obtained from the stomach. At this time the patient complained of severe pain in the epigastric area. Shortly afterward the patient sustained a massive hemorrhage and died. Permission for a postmortem examination was refused.

As may be noted in figure 6, this patient received corticotropin gel as part of the treatment of the severe exacerbation of her disease, and this may have been a contributing factor leading to the colon perforation. The severe vascular collapse during operation was probably due to the combined effects of malnutrition, sepsis, and adrenal insufficiency, but it responded to blood and hydrocortisone given intravenously. The patient improved after operation until the sudden onset of a fatal gastrointestinal hemorrhage. It is entirely possible that the operative stress and steroids resulted in a peptic ulcer and the terminal hemorrhage.

Comment

It seems clear that certain acutely ill or injured patients may exhibit signs of adrenocortical insufficiency during or after an operation. In the first example presented (fig. 1), a previously healthy patient with a severe intestinal obstruction remained in a shock-like state despite massive intravenous fluid therapy. It was not until hydrocortisone sodium succinate was administered that the blood pressure rose to normal levels and remained relatively stable.

The value of hydrocortisone in major surgery has been reviewed by Rukes and associates.[11] They found the drug useful in patients requiring bilateral adrenalectomy, in patients with adrenal insufficiency after major surgery, and in patients in shock unresponsive to standard therapy. A total of 50 patients of this type were treated, usually for no longer than five days. No complications of the treatment were noted.

Patients who have been on long-term steroid therapy and require operation certainly are more prone to adrenal insufficiency than is the average patient. Preparation for operation with steroids is not difficult and need not be extended for prolonged periods after operation. It is true that some of these patients might tolerate operation without steroids being given preoperatively; however, we believe it is much safer to prepare them all with steroids in order to prevent an unexpected adrenal insufficiency during or immediately after operation.

We have found corticotropin helpful in improving operability in selected patients by causing a marked improvement in appetite, increased food intake, and feeling of well-being. It by no means produces these effects in every patient. In general, those patients with lesions of the mouth or jaw or with obstructive lesions of the gastrointestinal tract are not suitable for this type of therapy. Now that intravenous solutions of fat and of concentrated protein hydrolysate are available, it is not difficult to effect weight gain by this parenteral therapy prior to operation. We believe it is preferable to achieve increased food intake and weight gain by the oral route if possible, and corticotropin may provide just the additional stimulus needed to bring certain patients into optimal preoperative condition.

Summary

The most important condition in which steroids are useful in treating surgical patients is that of acute adrenal insufficiency after severe injury or illness. The most prominent sign of this condition is persistent hypotension which cannot be explained by blood loss or coronary disease and which does not respond to adequate blood replacement. In these conditions, rapid, adequate therapy with hydrocortisone administered intravenously may be lifesaving. Patients requiring operation who have been on long-term steroid therapy present the hazard of adrenal depression and an acute insufficiency during operation. We believe that the safest procedure is to prepare all of these patients with steroids prior to operation. Corticotropin may be of value before operation by effecting a feeling of well-being and increasing appetite and food intake. Other beneficial effects of corticotropin include suppression of fever, toxicity, and malaise in conditions such as regional enteritis, and diminution of hypersensitive reactions in hemolytic anemia or thrombocytopenic purpura. Under such circumstances, when operation is contemplated in patients acutely ill with ulcerative colitis or purpura (less commonly with regional enteritis), administration of corticotropin may result in so much improvement that operation is made safe instead of being extremely hazardous. Contraindications to the use of steroids include active tuberculosis, malignant hypertension, uremia, psychoses, and the presence of active ulcers in the gastrointestinal tract.

These studies were supported, in part, by a grant from The Upjohn Company, Kalamazoo, Mich.

DEATH OF THE FETUS IN UTERO.—The woman is definitely aware of . . . her pregnancy from the moment that she feels life. . . . She keeps careful watch on the fetal movements, and her obstetrician asks about them and routinely checks the fetal heart sounds. . . . Life inside stirs her imagination. . . . All of a sudden, she realizes that she has not felt the fetal movements for a few hours or even a day. She becomes panicky and immediately calls the obstetrician. No matter how busy he may be . . . it is imperative that he see her at once. It may be a false alarm. Many are, and if so, there will be great relief. But if the fetal heart has stopped beating, and he is unable to hear it, he is there . . . to confirm the fact, to transmit it gently and to be of comfort. . . . We can be of the greatest help if we run over . . . in our mind's eye the psychological factors that all at once begin to shake the patient: loss of status, a sense of failure, loss of confidence and courage, frustration, disappointment and sorrow. Many questions will be asked. The answers must be honest and compassionate. We must search to explain the cause of death. Was it diabetes, toxemia, anoxia from a tight cord around the neck, trauma? The cause of death must be explained. . . . The patient must be absolved of guilt, else she will brood and think dark thoughts that may injure her self esteem. She may over-react and blame herself for doing that forbidden chore, for washing floors on hands and knees contrary to the advice of in-laws, for taking a long automobile ride, for getting unduly excited over some problem. . . . Some women blame sexual intercourse for the death and project all their wrath upon their husbands, creating a wound in their marriage that will be difficult to heal. The obstetrician must eliminate doubt and guilt, be sympathetic about this setback and optimistic about the future. . . . The responsibilities of her doctor have not ended, however. . . . All thoughts must be centered on her safe deliverance. . . . It must be explained . . . that we must wait for nature to initiate the birth process, for artificial interference may lead only to trouble and greater misfortune. She should be told that when a baby dies in utero and remains undelivered for some time, fibrinogen depletion may cause postpartum hemorrhage. But there are reliable tests for this condition, and an adequate supply of blood is available if transfusion becomes necessary.—A. D. Elia, M.D., The Management of Grief Situations in Obstetrics, *The Boston Medical Quarterly*, March, 1959.

HEALTH PROBLEMS IN EDUCATION

THE fitness of youth has interested the American physician for a long time. At the first American Medical Association meeting in 1848 a standing committee was established to "present an annual report" on a number of items, among which were educational institutions "and their relations to the laws of life." Thirty years later a committee of the Association further resolved that medical men ought to have a voice in the health aspects of the construction and location of public school buildings. The committee also felt physicians should have something to say about the age at which children should be admitted, the hours of study, and the general management of these institutions as these relate to health and expressed the belief that one or more physicians should serve on boards of education, boards of trustees, and similar boards having control of education and schools.

Among the instrumentalities for carrying out this expressed interest has been the Joint Committee on Health Problems in Education which the American Medical Association shares with the National Education Association. For nearly a half-century it has expressed the interest of physicians in education and the cooperation of educators and physicians by passing resolutions and preparing publications concerned with the health of children, school health and safety, and health education.

The entire process of elementary and secondary education has been subjected to a critical reevaluation during the decade known as the "atomic era" and, more particularly, in the "post-sputnik" period. There has been increased emphasis on the "three R's" and the physical sciences particularly. Physics and mathematics have dominated the educational scene, sometimes to the neglect of the biological sciences, health education, and physical education. To emphasize the essentiality of placing health education and physical education in proper perspective in the curriculum, the Joint Committee on Health Problems in Education reaffirmed its belief in the need for including these in the curriculum of elementary and secondary schools. The Joint Committee urged the employment of teachers especially qualified to teach health by reason of special preparation in health education and the acceptance of a comprehensive instruction program including such areas as nutrition, safety, first aid, body care, prevention of disease, community health, consumer education, mental health, emotional health, dental health, the deleterious effects of alcohol, tobacco, and drugs, and other important topics relating to life and living. Sufficient instructional time was suggested to allow for a stimulating and challenging program. This would mean at least the equivalent of a daily period for one year in junior high school and one year in senior high school.

Physical education as well as health education is an essential factor in the development of our youth. Because of the rather universal acceptance of physical activity as a desirable factor in physical, mental, emotional, and social well-being and in the maintenance of health, the Joint Committee on Health Problems in Education urged boards of education, school authorities, and physical education personnel to provide adequate facilities and suitable personnel for the development of physical education programs that would be an integral part of the school curriculum. Such instruction would develop a variety of activity skills and abilities for all boys and girls. Cooperation with other community agencies would assure broad opportunities for participation in vigorous physical activities both in and out of school hours for all pupils.

To further emphasize the physician's role in the entire health and physical education program, practicing physicians were urged by the Joint Committee to stimulate their colleagues' interest in and support for comprehensive programs of health education, health service, physical education, and athletics in the school. Physician interest in these areas of health science will insure the medical soundness that can be given only by medical understanding and supervision of activity programs. In fact, the Joint Committee on Health Problems in

Education and the National Conferences on Physicians and Schools, sponsored by the Department of Health Education of the American Medical Association, exist to help promote a closer relationship between physicians and the educators administratively responsible for our schools. Only by physician interest and concern can the health protection of our children be assured.

School transportation is a problem in health protection and accident prevention. With an increase in use of the school bus comes an increase in the school day, in the period of inactivity required of children, in the increased contacts with infectious material, particularly streptococci, and in the exposure to hazards of highway travel. With these problems in mind, the Joint Committee on Health Problems in Education recommended that every effort be made consistent with safety to avoid excessive time spent riding the school bus and to prevent children who are ill from riding the bus. Furthermore, the necessity was recognized for keeping the bus clean, comfortable, well-ventilated, and appropriately heated and for compliance with existing state and federal laws and regulations regarding the safe operating conditions of the bus, essential first-aid equipment, and fire extinguishers. The Committee also recommended that every bus driver should be required to have a physical examination at least annually and to otherwise conform to standards generally accepted for operators of commercial vehicles.

The American Medical Association's Council on Industrial Health called the attention of the Joint Committee to carbon tetrachloride as a toxic agent. This solvent is carefully regulated in industry to protect employees against hazardous overexposure. Yet this dangerous chemical is commonly found in laboratories and classrooms used in teaching chemistry and physics. It enters into experiments involving evaporation, solution, and other similar problems, and in the automotive and other shops of the school it is used as a degreasing agent. A resolution of the Joint Committee on Health Problems in Education called the attention of school administrators and teachers to the hazards associated with carbon tetrachloride, particularly since it is sometimes termed a "safety" solvent because it is not flammable, and some science textbooks and manuals call for its use without adequate warning of its hazards or a statement of the precautions to be taken for its safe use. The Committee also wished to call the attention of the publishers of science textbooks to this danger.

Protecting the health of our children and youth, and instructing them in the principles of healthful living, is a never-ending job. While the physician's responsibility in this task was recognized more than a century ago, today it is as true as then that physicians, educators, and the various professions in public health must work together to maintain the maximum protection and provide the optimum instruction. The contribution of the Joint Committee on Health Problems in Education of the National Education Association and the American Medical Association is but one of many such contributions being made by these two professions, but it is a significant one which has been going on for nearly a half-century.

ALL DUES-PAYING MEMBERS WILL RECEIVE THE JOURNAL AND A SPECIALTY JOURNAL

The House of Delegates at the Atlantic City meeting in June endorsed a new policy adopted by the Board of Trustees whereby all dues-paying members of the Association will receive The Journal and one of the A. M. A. specialty journals as a dues-paying membership benefit. Dues-paying members may select any one of the 10 A. M. A. specialty journals in the fields of internal medicine, surgery, ophthalmology, children's diseases, otolaryngology, pathology, dermatology, industrial health, neurology, or psychiatry. Thus, in all, such members will receive as a benefit of membership an A. M. A. specialty journal of their choice, *Today's Health, The AMA News,* and The Journal. Since the range of The Journal extends across the entire field of medicine, the House of Delegates and the trustees believe that all members of the Association should receive The Journal in addition to the specialty journal of their choice.

The dues-paying members who are not now receiving The Journal because they chose to receive a special journal will begin receiving The Journal within a few weeks. The 142,000 dues-paying members who already receive The Journal will receive an announcement asking them to choose one of the 10 scientific monthly journals, which will then be sent to them when their choice is made known to the Circulation and Records Department.

CHANGE OF ADDRESS

If you change your address please notify The Journal at least six weeks before the change is made. Include the address label clipped from your latest copy of The Journal, being sure to clearly state both your old and new address. If your city has Postal Zone Numbers, be sure to include this Zone Number in your new address.

MEDICAL NEWS

ARKANSAS

Symposium on Trauma.—The Union County Medical Society will sponsor a Symposium on Trauma given by the department of surgery, Washington University, School of Medicine, St. Louis, on Sunday, July 26, at the Randolph Hotel Building, El Dorado, Ark. A Flying Physician's breakfast is planned for 8:00 a. m. The following papers by St. Louis authors are scheduled:

Intraabdominal Injuries, Dr. James M. Stokes.
Head Injuries, Dr. William S. Coxe.
Thoracic Injuries, Dr. Charles L. Roper.
Hand Injuries, Dr. Arthur H. Stein Jr.
Injuries to the Genitourinary Tract, Dr. Charles H. Nicolai.
Spinal Cord Injuries, Dr. Coxe.
Injuries to the Peripheral Blood Vessels, Dr. Stokes.
Blood and Fluid Replacement in Trauma, Dr. Harvey R. Bernard.

The afternoon session will include a motion picture, a paper, "Relationship of Civil Defense to the General Practitioner," by Mr. Owen Payne, state civil defense chairman, and a concluding panel discussion conducted by Dr. Stein. For information write Dr. Berry L. Moore, 218 Masonic Temple Building, El Dorado, Ark.

CALIFORNIA

Dr. Hayes Honored.—Dr. Edward W. Hayes Sr., associate professor of thoracic diseases, College of Medical Evangelists, Loma Linda and Los Angeles, received the annual alumni achievement award from the Alumni Association of Carleton College, Northfield, Minn., for "distinguished service to the medical profession and devotion to the College." Only 48 persons in the history of the 93-year-old college have received the honor. Dr. Hayes is a past-president of the American College of Chest Physicians.

Society News.—The California Society of Plastic Surgeons held its ninth annual meeting April 9-11. The new officers for 1959-1960 are: president, Dr. George V. Webster, Pasadena; vice-president, Dr. Harry M. Blackfield, San Francisco; secretary-treasurer, Dr. Richard A. Shepard, Oakland; and historian, Dr. James B. Johnson, Beverly Hills.——The new officers of the Los Angeles Pediatric Society are: Drs. Morris J. Naiditch, president; Lawrence S. Siegel, vice-president; and Neil N. Litman, secretary-treasurer.

Personal.—Dr. Arild E. Hansen, chairman, department of pediatrics, University of Texas Medical School, Galveston, was appointed research director at Children's Hospital of the East Bay, Oakland, succeeding Dr. Irvine McQuarrie, who will continue as research consultant. Dr. Hansen will assume his duties in midsummer.——Dr. Charles M. Stewart, Los Angeles, who has been secretary-treasurer of the Western Section, American Urological Association, for the past six years, was unanimously voted president-elect of the section for 1961. Dr. John W. Dorsey, 125 E. 8th St., Long Beach, was elected the new secretary-treasurer.

Department of Virology.—A new department of virology was established on the Berkeley campus of the University of California. It is reportedly one of the first departments in any major university to be dedicated to the study of viruses and will be closely associated with the 10-year-old Virus Laboratory on the Berkeley campus. Chairman of the new department is Dr. Wendell M. Stanley, Nobel Laureate and director of the Virus Laboratory. Eight faculty members, drawn from the laboratory, comprise the staff of the department. Starting in September, lecture courses will be offered to graduate and advanced undergraduate students, to be followed later by a comprehensive laboratory course. Additional instruction will be offered, mostly at the graduate level, in the form of special study courses, seminars, and research projects. The main objective of the teaching program in virology will be to provide persons well grounded in biology, chemistry, or physics with "intensive specialized instruction" in the biochemical, biological, and biophysical aspects of virology. No change is anticipated in the over-all research program of the Virus Laboratory. The program of formal courses and research will lead to the master of science degree with a major in virology, or to the doctor of philosophy degree. The department is now accepting applications from qualified students. A limited number of teaching and research assistantships are available.

COLORADO

Report on Building Program.—The $17,500,000 building program proposed for the University of Colorado Medical Center was aided with recent action by the Colorado Legislature's Joint Budget Committee in approving the development of detailed plans. The six-man body unanimously approved an expenditure of $239,000 for development

---

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. Programs should be received at least three weeks before the date of meeting.

of the plans. The proposed building program calls for a new 400-bed hospital, a research building, a dental school, and expanded space for the School of Medicine and the School of Nursing. It will require about 1½ years to complete the plans. Meanwhile, additional legislature hearings will be held to discuss methods of providing the necessary state funds required for the project. The Medical Center currently has $6,000,000 in building mill levy funds for the project, and a matching grant of $1,300,000 from the U. S. Public Health Service.

CONNECTICUT

Dr. Richards Becomes General Manager.—Dr. William R. Richards, Hamden, assumed full-time duties in the newly created post of general manager of the Connecticut State Medical Society. He was appointed to the new position after having served one year as part-time executive secretary of the society. Dr. Richards has discontinued his medical practice in obstetrics and gynecology in New Haven, where he has had an office since 1946. He is a past-president of the New Haven Obstetrical Society and a diplomate of the American Board of Obstetrics and Gynecology.

State Medical Election.—Dr. Ellwood C. Weise, Bridgeport, assumed office as president of the Connecticut State Medical Society and was succeeded as president-elect by Dr. John N. Gallivan, East Hartford, at the annual meeting of the society. Other officers elected included: Drs. G. Gray Carter, Greenwich, first vice-president; Roy C. Ferguson, Rockville, second vice-president; Isadore S. Goldberg, Torrington, treasurer; William R. Richards, New Haven, executive secretary and general manager; and Denis S. O'Connor, New Haven, managing editor of *Connecticut Medicine,* the society's official publication.

ILLINOIS

Chicago

Aid for Disabled Physicians.—The Adolph Gehrmann Fund of the Chicago Community Trust provides for financial aid to practicing physicians who are in need of financial assistance while regaining their health. Their widows may be eligible for assistance for not more than one year following their physician-husband's death. Apply to Chicago Community Trust, 10 S. LaSalle St., Chicago 3.

Society News.—Dr. Theodore R. Van Dellen, associate professor of medicine, Northwestern University Medical School, was named president-elect of the Chicago Medical Society at the society's council meeting recently. Dr. George C. Turner, designated president-elect in 1958, was installed as president for 1959-1960 on June 24, succeeding Dr. Edwin F. Hirsch. Dr. Patrick H. McNulty was reelected secretary.——Officers for the 16th season (1959-1960) of the Chicago Surgical Society were elected at the annual business meeting May 22 as follows: Dr. John L. Keeley, president; Dr. John V. Prohaska, vice-president; Dr. Robert L. Schmitz, secretary; Dr. Burton C. Kilbourne, treasurer; Dr. Tracy H. Clarke, recorder; and Drs. Francis H. Straus, John M. Dorsey, and Charles B. Puestow, councilors.

Chairman for Physiology Department.—Prof. Dwight J. Ingle, Ph.D., hormone researcher, was appointed chairman of the University of Chicago's department of physiology, effective July 1. He succeeds Prof. Nathaniel Kleitman, Ph.D., who has been acting chairman of the department since the resignation of Prof. John O. Hutchens Sept. 30, 1958. Drs. Kleitman and Hutchens are professors of physiology. Earlier this month, Professor Ingle returned from a tour of research centers in Russia sponsored by the U. S. Public Health Service Institute of Arthritis and Metabolic Diseases. The discoverer of the biological effects of the hormones cortisone and hydrocortisone, Professor Ingle was the George S. Cox Medical Research Fellow at the University of Pennsylvania from 1938 to 1941. He holds the 1947 award of the Laurentian Hormone Conference in Biology and the 1948 W. E. Upjohn Prize.

Personal.—Dr. Gilbeart H. Collings Jr., medical director of Crane Co., Chicago, since 1957, following service with the U. S. Army Medical Corps at the Army Environmental Health Laboratory, was appointed to the new position of associate director of the medical department of Standard Oil Company (Indiana). Previously he had been with the Tennessee Valley Authority as chief of the occupational health branch, and with Bethlehem Steel Co.——Dr. Percival Bailey, professor of neurology and neurological surgery and clinical professor of psychiatry, University of Illinois College of Medicine, will retire from the university on Sept. 1 and become full-time director of research at the new Illinois State Psychiatric Institute.——Dr. Frederick E. Vultee Jr. was appointed associate director of the Rehabilitation Institute of Chicago. Dr. Vultee was formerly an associate professor of physical medicine and rehabilitation at the Medical College of Virginia, Richmond.

International Awards for Film.—Two international awards for excellence of a scientific film were presented to Dr. Hans Von Leden, assistant professor of otolaryngology, Northwestern University Medical School, and G. Paul Moore, Ph.D., lecturer in the same department. The U. S. Department of State sent notice of the awards recently, although the film festivals were held several months ago. The film, "The Larynx and Voice—Laryngeal Physiology Under Daily Stress," was one of 320 entries in the fourth International Review of Scientific Films held in Rome. All branches of science were represented at the film festival. Dr. Von Leden's film was awarded the Gold Medal of the Italian Red Cross and was one of the few films of a medical subject to receive a prize. This was presented to the United States representative in Rome and was reportedly the only major prize won by the United States at this festival. The second award was won at the Third International Review for Scientific Education at the University of Padua under the sponsorship of the international film festival in Venice. The award to the Northwestern scientists was for "education in the field of medicine." They were also presented with a bronze ox head—the traditional gift at the University of Padua for awards of merit. During the past three years, Drs. Von Leden and Moore have won five international awards for their work in laryngeal physiology.

NEW JERSEY

Fitkin Hospital Symposium.—On July 18, Fitkin Memorial Hospital Day, a medical symposium will be held at the hospital in Neptune. The program includes the following papers and speakers:

Fetal Distress—Evaluation and Management, Dr. Alan F. Guttmacher, New York City.
Clinical Experiences with Pancreatitis, Dr. John M. Howard, Philadelphia.
Newly Isolated Viruses in Respiratory Disease, Dr. Robert H. Parrott, Washington, D. C.
Pulmonary Hypertension, Dr. Richard S. Ross, Baltimore.

The general chairman for the symposium is Dr. Samuel H. Rubin, Director, Department of Medical Education, Fitkin Memorial Hospital, Neptune, N. J. Information on the symposium may be obtained by writing Dr. Rubin.

NEW MEXICO

Summer Clinic in Ruidoso.—The New Mexico Academy of General Practice will present the Ruidoso Summer Clinic July 20-23 in Ruidoso, with headquarters at the Navajo Lodge. Four panel discussions are planned: "Steroids Today," "Psychosomatic Medicine," "Low Back Pain," and "Orthopedic and Urological Complication in Obstetrics." The program will include the following papers:

Common Fractures in General Practice, Dr. Arthur L. Glassman, Houston, Texas.
Office Gynecology, Dr. Stanley F. Rogers, Jr., Houston, Texas.
Management of Orthopedic Difficulties of the Newborn, Dr. Glassman.
Evaluation of Cephalo-Pelvic Disproportion, Dr. Rogers.
Management of Urinary Tract Infection, Dr. Abel Leader, Houston, Texas.

For information, write Dr. Owen C. Taylor Jr., Publicity Chairman, Ruidoso Summer Clinics, Fourth and Washington, Artesia, N. M.

NEW YORK

State Medical Election.—Dr. Norman S. Moore, of Ithaca, was chosen president-elect of the Medical Society of the State of New York by the House of Delegates at its 153rd annual meeting. Dr. Moore will serve for one year after which he will become president, succeeding Dr. Henry I. Fineberg, of Jamaica, who was installed as president. Dr. Fineberg succeeds Dr. Leo E. Gibson, of Syracuse. Also elected were Dr. John L. Sengstack, of Huntington, vice-president, and Dr. William L. Wheeler Jr., of New York City, secretary.

Personal.—Dr. Irvin Klein was appointed medical director of the New York State Workmen's Compensation Board. Dr. Klein, of New York City, has been an associate examining physician of the board since 1942. He succeeds Dr. Willis M. Weeden.—Richard H. Barnes, Ph.D., dean of the Cornell University Graduate School of Nutrition, Ithaca, was appointed editor of the *Journal of Nutrition.* He succeeded George R. Cowgill, Ph.D., of the Yale Nutrition Laboratory, who served as editor for 20 years. Cyril L. Comar, Ph.D., director of the Laboratory of Radiation Biology, New York State Veterinary College, has been appointed associate editor.

Reorganize Mental Hospital.—A program of reorganization is in process at Pilgrim State Hospital, Dr. Paul H. Hoch, New York State Commissioner of Mental Hygiene, announced. Under the new plan the 14,000-bed hospital will be decentralized into a cluster of 2,000- to 3,000-bed units each under the management of an assistant director who will discharge both clinical and administrative functions for the unit. Each division will be self-contained and will have its own admission service, treatment facilities, and release procedures. Certain of the institution facilities will be shared, however, such as the transportation and maintenance pools, the business office, etc. Plans for the reorganization have been worked out by Dr. Henry Brill, recently appointed director of Pilgrim. Preliminary work on the project began about a year ago. Two of the small units have already been established.

New York City

Dr. Swan Named Department Head.—Dr. Roy Craig Swan Jr. was named professor and head of the department of anatomy, Cornell University Medical College, by the board of trustees. He is also treasurer of the New York State Society for Medical Research.

Research and Library Building.—Cornell University received a grant of $1,600,000 from the Samuel J. and Evelyn L. Wood Foundation of New York. The grant, together with a matching grant of $1,300,000 from the United States Public Health Service, will be used toward the construction of a research and library building for the Cornell University Medical College. Cost of the new building will be about $3,200,000. The new building, a seven-story structure at 1300 York Avenue, will be named the Samuel J. Wood Library and Research Building. It will provide the Medical College with about 50,000 square feet of additional space, which will be used by Cornell students and faculty and by staff members of the Sloan-Kettering Institute, New York Hospital, Memorial Hospital, the Cornell University-New York Hospital School of Nursing, Hospital for Special Surgery, and the Rockefeller Institute. Samuel J. Wood, after whom the new building will be named, and his wife established the Wood Foundation in 1958 with the objective of furthering medical research in this country.

Dedicate Rehabilitation Wing.—Dedication ceremonies opening the new $500,000 Maurice B. Hexter Rehabilitation Wing at Beth Abraham Home for the Chronic Ill, 612 Allerton Ave., the Bronx, were held June 23. Mayor Robert F. Wagner, speaking at the ceremonies, pointed out the city's pilot "Homestead Plan" and program to help the chronic disabled and aged. Undertaken at the suggestion of Dr. Howard A. Rusk, the program provides 1856 beds in five separate institutions located in different parts of the city. The new rehabilitation center is named for Maurice B. Hexter, Ph.D., executive vice-president of the Federation of Jewish Philanthropies of New York. The wing houses the division of physical medicine and rehabilitation including the departments of physical therapy, hydrotherapy, electrotherapy, occupational and speech therapy, recreation, and music. The new rehabilitation center is housed on the ground floor of Beth Abraham's recently opened $3,500,000 Henrietta and Stuard Hirschman Pavilion. Beth Abraham Home, a 531-bed nonprofit institution, is affiliated with and receives its major philanthropic support from the Federation of Jewish Philanthropies.

OHIO

Training Positions in Infant Neurology.—Training in developmental pediatrics and infant neurology is available for board eligible physicians at the Clinic of Child Development of the Children's Hospital, Columbus, on two levels. The first is a fellowship for physicians, preferably pediatricians, recently completing their residencies, with an opportunity to continue at faculty status in the teaching and research program. American citizenship is required. For those with additional qualifications, whether in pediatrics or in other fields, there is available a full-time staff appointment in the department of pediatrics of the Ohio State University College of Medicine, with major responsibility in teaching and research. For information write to the Clinic of Child Development, Children's Hospital, 561 S. 17th St., Columbus 5, Ohio.

PENNSYLVANIA

Dr. Hess Gives Annual Doyle Lecture.—The second annual Dr. Joseph A. Doyle memorial lecture was given April 30, at Thiel College, Greenville, by Dr. Elmer Hess, Erie. The title of the lecture was "The Future of Medicine In the United States." Dr. Doyle, to whose memory the lectures series is dedicated, was a surgeon in the Greenville area from 1920 until his death in 1947. He was one of founders and a member of the staff of the Medical Center Clinic of Greenville. The lectures "represent an effort on the part of Medical Center Clinic to honor Dr. Doyle, while promoting interest in the medical program offered at Thiel College." Dr. Hess is a past-president of the American Medical Association, Pennsylvania Medical Society, and the American Urological Association. He has served as chief of staff at St. Vincent's Hospital, Erie, since 1941.

TEXAS

Medical Assembly in Houston.—The 25th annual meeting of the Postgraduate Medical Assembly of South Texas will be held July 20-22 at the Shamrock Hilton Hotel, Houston. The program will include lectures under medical and surgical specialties. Luncheon speakers will include Dr. Walter C. Alvarez, Minneapolis; Dr. Alton Ochsner, New Orleans; and Dr. F. J. L. Blasingame, Executive Vice-President, A. M. A., Chicago. Other guest speakers include the following:

> Drs. Fred H. Allen Jr. and Charles L. Schepens, Boston; A. E. Braley, Iowa City; Louis Thomas Byars, St. Louis; George F. Cahill, New York City; Tague C. Chisholm and Charles A. Neumeister, Minneapolis; J. Brown Farrior, Tampa, Fla.; Francis L. Lederer, Chicago; Donald B. Lucas, San Francisco; Vincent Moragues, Omaha; H. M. Pollard, Ann Arbor, Mich.; Clyde L. Randall, Buffalo, N. Y.; Robert N. Rutherford, Seattle; Wiley Mitchell Sams, Miami; Louis J. West, Oklahoma City, Okla.; Lawrence E. Young, Rochester, N. Y.; and Morton Fuchs, Philadelphia.

Technical and scientific exhibits and a program of medical motion pictures are planned, and a program of entertainment is arranged. Registration fee is $25. For information, write the Postgraduate Medical Assembly of South Texas, 412 Jesse H. Jones Library Building, Houston 25, Texas.

WASHINGTON

Housing for Hospital Staff.—Contracts for the 39-unit University Hospital staff housing project at the University of Washington, Seattle, to be financed by a loan from the Federal Housing and Home Finance Agency, were awarded by the university's board of regents. The project is budgeted at $400,000, including contingencies, fees, and taxes, and will be self-sustaining on the basis of rentals. The apartments will provide quarters for married interns and residents who must be on 24-hour call at the new University Hospital. Completion date will be about Dec. 1.

WISCONSIN

Dr. Haessler Retired.—Dr. Ferdinand Haessler, Marquette University School of Medicine's first full-time professor in the clinical departments, retired July 1. Dr. Haessler has been chairman of the department of ophthalmology since Jan. 15, 1949, when an anonymous benefactor established the first full-time chair of ophthalmology. Dr. Haessler devoted his time to the management of the eye clinic and dispensary in the medical school, to teaching, and to the development of a training program for physicians interested in a career in ophthalmology.

Dr. Rath Named Medical History Chairman.—Appointment of Dr. Gernot B. Rath, of the University of Bonn, Germany, as chairman of the history of medicine in the University of Wisconsin Medical School, Madison, was approved by university regents June 9. Dr. Rath, who will have the rank of associate professor, had been visiting professor of medical history during the second semester of the 1958-1959 school year. The appointment is effective Jan. 1, when Dr. Rath will return to Wisconsin from Germany. The Wisconsin Medical School reportedly was a pioneer in the field of medical history teaching and research, setting up a department for that purpose in 1950. Two other European-trained scholars have participated in the program. Dr. Erwin H. Ackerknecht served as chairman from 1950 to 1957. He came to Wisconsin in 1947 as the first professor of medical history in the Medical School. Dr. Walter Artelt, of the University of Frankfurt, was visiting professor of the history of medicine in 1958.

GENERAL

Japan's First Woman Physician Dies.—Dr. Yayoi Yoshioka, 88, Tokyo, Japan's first woman physician and founder of the Tokyo's Women's Medical School, now Tokyo's Women's Medical College, of which she was president, died May 23. She had taught at the Medical School and College for more than 50 years and had helped to establish hospitals in Tokyo.

Postpone Examination in Nuclear Medicine.—The board of trustees of the American Board of Radiology has decided to postpone the obligatory examination in nuclear medicine until after June 30, 1962, for those candidates being examined in radiology or therapeutic radiology. Up until that time, therefore, the examination in nuclear medicine will be optional for those who wish to be examined in radiology or therapeutic radiology.

Medical Degree Stolen.—The medical degree of Dr. John Philip Brady, Tillamook, Ore., under the date of June 15, 1925, given by the University of Michigan Medical School, Ann Arbor, has been stolen. Dr. Brady was licensed in Minnesota in 1929 and in Oregon in 1954. These are the only states in which he is licensed to practice. Persons having knowledge of the stolen degree should notify Mr. Howard I. Bobbitt, Executive Secretary, State of Oregon Board of Medical Examiners, 609 Failing Building, Portland 4, Ore.

Dr. Grantly Dick Read Dies.—A pioneer of "natural" childbirth techniques, Dr. Grantly Dick Read, died at his home in Wroxham, England, June 11. He was 69. Dr. Dick Read practiced as a gynecologist in London from 1923 to 1948. In 1949 he went to Johannesburg, South Africa, to set up a world center for childbirth without pain. His books include "Childbirth Without Fear," "Introduction to Motherhood," and "No Time for Fear." In 1956 Dr. Dick Read undertook a special trip to the Belgian Congo to study tribal practices in obstetric cases.

Prize Essays in Dermatology.—Dr. J. Graham Smith, of Miami, read his prize winning essay "The Aged Human Sebaceous Gland," at the 79th annual meeting of the American Dermatological Association, Inc., in June. Other prize winners in the annual contest were Dr. James H. Graham, of Philadelphia, and Dr. Elson B. Helwig, of Washington, D. C., "Bowen's Disease and Its Relationship to Systemic Cancer," second prize; Dr. Troy G. Rollins, of Woodland, Calif., "Necrobiosis Lipoidica Diabeticorum and Necrobiosis Lipoidica Granulomatosis," third prize; and Dr. Daphne Anderson Roe, of Wilmington, Del., "The Psoriatic Process," fourth prize. Papers for the 10th annual essay should be submitted to the Secretary, Dr. Wiley M. Sams, #308 Ingraham Building, Miami 32, Fla., not later than Nov. 15.

Announce Pediatric Award.—Applications are invited for a prize to be awarded by the Foundation Ernesto Cacace for Nepiology to the "best writer graduated from an Italian or foreign University or high institution of learning" on the subject, "Pathology and Medical Clinic of the Lactant Infant." The amount of the award will be 350,000 lire. Deadline for the presentation of the papers in six copies preferably in Italian is Dec. 31, 1961. Papers should be addressed to the Permanent Secretary of the Jury, Dr. Piero Repetto, Via Morghen 4, Turin, Italy. The award jury is composed of the foundation president and four members of the university staff. In the event this competition does not result in an award, the amount of the prize will be added to the funds of the foundation. Information may be obtained from Dr. Repetto.

Problems of the Crippled.—The 1959 annual convention of the National Society for Crippled Children and Adults, with sessions keyed to the theme "Searching Out Solutions," will be held in the Palmer House, Chicago, Nov. 29-Dec. 2. A training program for boards, volunteers, professional care, and treatment and administrative staffs of national, state, and local crippled children's societies, workshops will be devoted to "upgrading all facets of Easter Seal activity," according to Dr. Dean W. Roberts, executive director. The workshops will make case studies of problem areas with a view to developing solutions. The year 1959 marks the 38th anniversary of the National Society for Crippled Children and Adults. It has 1,655 Easter Seal affiliates in the 50 states, District of Columbia, and Puerto Rico, and aided almost 250,000 crippled children and adults in 1958.

Conference on Transmissible Animal Diseases.—The second annual Midwestern Interprofessional Conference on Diseases of Animals Transmissible to Man will be jointly sponsored by the State University of Iowa College of Medicine and the Iowa State Department of Health at Iowa City Sept. 10-11. The subjects will include brucellosis, rabies, leptospirosis, Q fever, staphylococcic diseases, and others. Presentations will be made by veterinarians and physicians and will emphasize the public health aspects and recent advances in these fields. This annual conference, the first of which was held at Omaha in 1958, will be held on a continuing annual basis sponsored in rotation by the academic institutes of the midwestern states. For information, write Dr. Ian Maclean Smith or R. A. Tjalma, D.V.M., State University of Iowa, University Hospitals—Department of Internal Medicine, Iowa City, Iowa, co-chairmen.

Summer Research Fellowships.—Summer research fellowships totaling $115,000 will be awarded this year to medical students in 97 U. S. and Canadian medical schools it has been announced by Lederle Laboratories Division, American Cyanamid Company. In a letter to medical schools, Dr. Benjamin W. Carey, Lederle medical director, stated that the medical student research fellowships are intended "to relieve in part the financial burden of students who desire to devote their summer vacations to research in the preclinical departments." Each four-year school receives $1,200 to be awarded to not less than two students, while each two-year college receives $600. Selections of the recipients of the fellowships are made by the deans of the medical schools. The Lederle fellowships have been given annually for six years. During this time almost $700,000 has been awarded to assist more than 1,000 medical students in this country, Puerto Rico, and Canada.

Mechanisms Concerned with Conception.—The Population Council, Inc., and the Planned Parenthood Federation of America, Inc., will present a conference, "Physiological Mechanisms Concerned with Conception," July 29-31, at the Hotel Thayer, West Point, New York. The conference will include the following topics:

Spermatogenesis and Sperm Physiology.
Physiology of Male Accessory Organs.
Ovogenesis and Ovulation.
Sperm Migration in the Female.
Fertilization and Implantation Mechanisms.
Immunological Phenomena.

The six sessions will be preceded by two days devoted to discussions in work groups. The final plenary session and dinner, 7:30 p. m., July 31, will include a summary of the conference. For information write Miss Margaret Snyder, Research Administrator, Planned Parenthood Federation of America, Inc., 501 Madison Avenue, New York 22.

Plan Nutrition Congress.—The fifth International Congress on Nutrition will be held in Washington, D. C., Sept. 1-7, 1960. Organized by the American Institute of Nutrition and the U. S. A. National Committee for Nutritional Sciences of the National Academy of Sciences, the congress is under the auspices of the International Union of Nutritional Sciences. Officers are: honorary president, Elmer V. McCollum, L.L.D., Baltimore; president, C. Glen King, Sc.D., New York City; chairman, organizing committee, Dr. Paul Gyorgy, Philadelphia; and general secretary, Milton O. Lee, Ph.D., Washington, D. C. The scientific program will consist of seven panel discussions, special programs on nine topics, an all-day symposium, "Food Needs and Food Resources," and 10-minute papers reporting original research. There will be scientific and industrial exhibits, visits to various scientific laboratories, a special program for women guests, and general entertainment activities for all registrants. For information, write: The Secretariat, Fifth International Congress on Nutrition, 9650 Wisconsin Ave., Washington 14, D. C.

Aero Medical Association Changes Name.—At the 30th annual meeting of the Aero Medical Association the society changed its name to the Aerospace Medical Association. Effective with the June number, the *Journal of Aviation Medicine* will be known as *Aerospace Medicine.* The 29th president of the association is Dr. Ludwig G. Lederer, of Washington. Dr. George J. Kidera, Chicago, was named president-elect, and Capt. Oran W. Chenault, Washington, D. C., was elected first vice-president. The association announced plans to establish a national headquarters in Washington, D. C., in the near future under the direction of Dr. William J. Kennard Jr., who was elected secretary-treasurer. He succeeded Dr. Thomas H. Sutherland, Marion, Ohio, who retired after holding that office since 1947. The Raymond F. Longacre Award was given to Capt. George E. Ruff Jr., Wright-Patterson Air Force Base, Ohio. The Arnold D. Tuttle Award was won by Dr. Lawrence E. Lamb, of the Air Force School of Aviation Medicine. Capt. Edward L. Beckman, on duty at the Royal Naval Institute of Aviation Medicine, Farnborough, England, was awarded the Eric Liljencrantz Medal. Capt. Clifford P. Phoebus, Newport, R. I., received the Theodore C. Lyster Award.

Prevalence of Poliomyelitis.—According to the National Office of Vital Statistics, the following number of reported cases of poliomyelitis occurred in the United States, its territories and possessions in the weeks ended as indicated:

	June 20, 1959		June 21, 1958

Conference on Mental Retardation.—The first International Medical Conference on Mental Retardation will be held July 27-31 at the Eastland Hotel, Portland, Maine. Papers to be presented by foreign participants include the following:

Developmental Anomalies in the Region of the Foramen Magnum, Dr. John D. Spillane, Cardiff, England.
Infections and Mental Deficiency, Dr. H. Asperger, Innsbruck, Austria.
Prenatal Infections, Dr. J. Sutter, Algiers, Algeria.
Dietary Treatment of Phenylketonuria—Experiences Over the Last Nine Years, Dr. H. Bickel, Marburg, Germany.
Lipid and Carbohydrate Metabolism and Mental Deficiency, Dr. P. B. Diezel, Heidelberg, Germany.
Copper, Iron and Lead Metabolism and the Brain, Dr. John N. Cumings, London, England.
Chemical Basis of Phenylketonuria, Dr. Cumings.
Etiological Aspects in Mongolism, Dr. J. Øster, Randers, Denmark.
Therapy in Mental Deficiency, Dr. Karl Kundratitiz, Vienna, Austria.
Chromosomal Factors in Some Types of Intellectual Subnormality, Dr. Paul E. Polani, London, England.
Behavior Problems in Brain Damaged Children, Dr. Asperger.

Scientific and commercial exhibits, a program of film exhibits, and social activities are planned. For information, write Dr. Ella Langer, State House, Augusta, Maine, Conference Secretary.

Report on Growth in Families.—American families continue to grow in number and size, it is reported by statisticians of the Metropolitan Life Insurance Company. There were about 38 million husband and wife families in the United States in March, 1958, a gain of 5.75 million, or 18%, during the past decade. In the same period, the number of families with three children under age 18 increased 68%, and those with four or more dependent children increased by 59%. Currently, the chances are 40 in 1,000 that a white father aged 25 will die before his newborn child reaches age 18. The likelihood of orphanhood rises rapidly with the age of the father at the time the child is born. The chances mount to 59 at age 30, to 93 at age 35, to 146 at age 40, to 221 at age 45, and to 323 at age 50. The chances that a newborn child will lose its mother are 15 in 1,000 in the mother is 20 when the child is born; then climb to 22 at age 25, to 33 at age 30, to 50 at age 35, to 76 at age 40, and to 115 at age 45. The Metropolitan statisticians point out that the American people are increasingly making provision to meet the contingency of premature death through life insurance, systematic saving, and other means. At the end of 1958, about 112 million policyholders in the United States owned nearly 500 billion dollars of life insurance in private companies.

Rhinologic Meeting in Chicago.—The American Rhinologic Society will hold its fifth annual meeting in the Belmont Hotel, Chicago, Oct. 10. This will be preceded by a surgical seminar in the Illinois Masonic Hospital, Chicago, Oct. 7-9. Dr. Kenneth

H. Hinderer, Pittsburgh, president of the society, will preside. The scientific program will include a "Symposium on Objective Tests for Nasal Function." Papers will include the following:

Trans-Septal Pituitary Extirpation, Dr. Walter E. Heck, San Francisco.
Choices of the Rhinologist in Approaching the Tear Sac, Dr. Lester T. Jones, Portland, Ore.
Surgery of Nasal Malignancies, Dr. John J. Conley, New York City.
Tissue Reactions to Nasal Transplants, Dr. William B. Barry, Kansas City, Mo.
Basic Immunology of Bone Transplants, Dr. James A. Dingwall, Squibb Institute for Medical Research, New Brunswick, N. J.

A showing of a film, "The Human Nose," will follow the evening dinner. Introductory remarks will be made by Dr. Richard B. Hadley, Rye, N. Y. Physicians and guests are invited. There is no registration fee. For information write Dr. Robert M. Hansen, secretary, 1735 N. Wheeler Ave., Portland 12, Ore.

Foreign Poliomyelitis Immunization Programs.—An immunization program with Wistar Institute attenuated live virus oral poliomyelitis vaccine is planned by the Polish public health authorities for a group of children in Poland. Dr. Hilary Koprowski, director of the Wistar Institute in Philadelphia and originator of its poliomyelitis vaccine, announced the program. Dr. Koprowski also made known how an oral immunization program with Wistar vaccine under the auspices of the Belgian Congo public health authorities was used to protect children in the Belgian Congo against a poliomyelitis epidemic late in 1958 and early in 1959. The Polish program, scheduled to begin in June, will administer strains of Wistar Institute live virus poliomyelitis vaccine to children from 6 months to 7 years who have not yet had a third injection of Salk-type vaccine. Adoption of the Wistar oral live virus vaccine stems from an investigation begun last December by the Polish State Institute of Hygiene. Dr. Felix Przesmycki, director of the Polish State Institute of Hygiene, spent several months at the Wistar Institute studying the production of the vaccine. Dr. Koprowski discussed the immunization project with the Polish public health authorities on two visits to Poland during the last 12 months. Belgian Congo public health authorities decided on immunization of children and infants with Wistar Institute live virus oral poliomyelitis vaccine because their records indicated an increasing incidence of poliomyelitis in the Congo from 1951 through 1957. The program for Leopoldville now under way calls for immunization of 75,000 children between the ages of 6 months and 5 years with Type I Wistar Institute oral vaccine. Immunization in Leopoldville has proceeded at a rate of about 8,000 children a month, both native and European.

CANADA

Install Duke of Edinburgh as President.—The installation of His Royal Highness, Prince Philip, Duke of Edinburgh, as president of the Canadian Medical Association was held in Toronto Tuesday, June 30. Dr. Arthur D. Kelly, general secretary of the association said that His Royal Highness will not be accepting the presidency as an honorary appointment. "He will actually be our President for the ensuing year," said Dr. Kelly. "The event will be of historic interest, as this will be the first time that a nonmedical person has been appointed President of the C. M. A." Dr. Kelly also stated that the many duties of the office will be carried out by Dr. E. Kirk Lyon, of Leamington, Ontario, who has been elected Canadian Deputy to the President. Special guests at this ceremonial meeting of installation were Sir Arthur Thomson, of Birmingham, president, British Medical Association; Dr. Louis M. Orr, of Orlando, Fla., President, American Medical Association; and Dr. Emil Blain, of Montreal, president of l'Association des Médecins de Langue Française du Canada.

FOREIGN

Congress on Therapeutics.—The sixth International Congress on Therapeutics will be held Oct. 1-3 at the Palace of the University of Strasbourg, France. Three congress subjects have been chosen by the international committee: (1) the damages of abusive gastrectomies for gastroduodenal ulcer, (2) anti-inflammatory medications, and (3) antitussive medicines. A medical exposition is planned. Prof. R. Fontaine, dean of the Faculty of Medicine, University of Strasburg, is president of the congress, and Prof. F. Schmid, professor of pharmacology at the university, is the general secretary.

Meeting on Voice and Speech in London.—The 11th International Congress of Logopedics and Phoniatrics will be held Aug. 17-22, at the Kings College, London. Two symposiums are planned: "Common Traits in Normal Language Development, Dyslalia, Dyslexia and Aphasia," and "Pathologie der Resonanzraume bei Gaumenspalten." The program will include participants from the Netherlands, Spain, Hungary, Czechoslovakia, France, Sweden, Germany, Poland, Australia, the United States, and England. For information write Miss Peggy Carter, 46 Canonbury Square, London, N. 1, England, secretary of the congress.

Medical Congress in South Africa.—The Medical Association of South Africa will hold its 42nd medical congress Sept. 27-Oct. 3 in East London, Cape Province, under the presidency of Dr. P. F. Wagner. Three symposiums are planned for the plenary sessions on cancer, heart disease, and tuberculosis. Congress visitors will include the following: Sir Russell Brock, London; Dr. George E. Burch, New

Orleans; Prof. Robert McWhirter, Edinburgh, Scotland; Dr. Harold Stewart, Bethesda, Md.; Dr. A. Ravin, Denver; Dr. Rose Ravin, Denver; and Dr. Rex L. Diveley, Kansas City, Mo. A trades exhibition, a scientific exhibition, and an arts and hobbies exhibition are planned. A ladies' program and a program of sports and entertainment are arranged. For information, write Dr. E. McCabe, Honorary Organizing Secretary, Medical Congress Office, Third Floor, Ensuco House, 10-12 Oxford St., East London, South Africa.

Symposium on Depression.—The University of Cambridge, England, will hold a symposium on depression Sept. 22-26. The symposium will consist of lectures and discussions on the following aspects of the subject: (1) clinical, (2) neuro-pharmacological, (3) psychological, and (4) therapeutic. Lectures will be given during the morning with discussion by group in the afternoon. The aim of the symposium is to describe the growth of opinion and to give current views on the nature of depression and its treatment. The symposium, primarily intended for those engaged in the practice of psychiatry and for university research or teaching staffs, will be introduced by Prof. Aubrey Lewis, of London. Fee for the course is £6 6s. 0d.; part-time attendance is at the rate of £1 11s. 6d. per day. The proceedings will be in English and will be published by the Cambridge University Press. Registration forms may be obtained from the Secretary of the Medical School, Tennis Court Road, Cambridge, England.

CORRECTIONS

Highlights of Atlantic City Meeting.—In the section entitled Related Activities in Highlights of Atlantic City Meeting (June 27 issue, page 1076) the third line of the paragraph beginning "Meeting at the . . ." should follow the third line of the paragraph beginning "America's younger generation. . . ."

The Management of Cardiac Arrest.—In the article by Davis and associates in the June 27 issue on page 1051, the second sentence of the paragraph beginning "The thoracic cavity. . . ." should begin "One million units of penicillin . . ." instead of "One million cubic centimeters of penicillin. . . ."

President Coolidge Also Addressed the A. M. A.—The Journal, June 27, page 1072, stated that President Eisenhower's address before the Annual Meeting of the American Medical Association in Atlantic City, June 9, was the first time that the Association had been honored by the participation of the President of the United States in its program. The Journal now finds that President Calvin Coolidge addressed the opening meeting of the American Medical Association Tuesday, May 17, 1927, during the Annual Meeting of the Association in Washington, D. C.

Amphetamine Sulfate and Athletic Performance.—The study by Gene M. Smith, Ph.D., and Henry K. Beecher, M.D., in The Journal of May 30, 1959, page 542, was completed only a short time before publication. Development of the report and arrangements for printing it concurrently with public announcement of the recommendations of the American Medical Association's Special Committee on Amphetamines and Athletes were, therefore, necessarily hurried. For this reason some errors appeared in the paper. The authors did not receive proofs and had no opportunity to correct them before publication. Corrections have been made in the author's reprints. The essential corrections are as follows.

The Tables.—The data reported in table 2 were transposed in a typesetting error. The results reported under the heading "First Swim, Rested Condition" should have been presented under "Second Swim, Fatigued Condition" and vice versa. In the body of that same table the symbol $\overline{P}\text{-}\overline{A}$ should be $\overline{\overline{P}\text{-}\overline{A}}$ and the symbol $\frac{\overline{P}\text{-}\overline{A}}{\overline{P}}$,% should be $\frac{\overline{\overline{P}\text{-}\overline{A}}}{\overline{P}}$,%. The first note in the legend should read: $\overline{\overline{P}\text{-}\overline{A}}$ = mean difference for the group of $\overline{P}\text{-}\overline{A}$ scores presented in table 1. The second note should read: $\overline{\frac{\overline{\overline{P}\text{-}\overline{A}}}{\overline{P}}}$,% = mean difference . . . instead of: $\frac{\overline{P}\text{-}\overline{A}}{\overline{P}}$,% = mean difference . . .

Similar errors in symbol notation occurred in other tables, but if the tables are examined in relation to the text, they are understandable. Table 3 contains two numerical errors. Under the heading: "Swimming in competition, 3 Hr. After Medication," the p value fifth from the bottom should be 0.02 rather than 0.20. In the third column from the right the value −0.30 should read −0.39. In table 14, the second column from the right reports the value of −0.31. The sign should have been plus rather than minus. The tables in the author's reprints have the correct symbols and numerical values.

Errors in the Text.—The section on Medicaments (pages 542 and 543) may be misleading. The point to be clarified is this: Each subject participating in a given experiment was studied under all types of medication used in that experiment and was studied under each agent several (three on the average) times.

On page 545, in the first paragraph under Method, *Experiment 3*, the sixth sentence reads: "The subjects were given 14 mg. of amphetamine per 70 kg. on two occasions, with 50 mg. of secobarbital per 70 kg. on two and with placebo on two." The word "with" should have been deleted both times in that sentence. The point to be clarified is this: No subject took both amphetamine and secobarbital on the same day.

On page 550 under Results, *Experiment 1*, the seventh paragraph begins: "Table 1 . . ." It should read: "Table 2 . . ." In that same paragraph the following material should have been deleted:

"(mean placebo minus mean amphetamine/mean placebo)." In the tenth paragraph of that same section the sentence beginning, "The 10-yd. men . . ." should read, "The 100-yd. men . . ."

On page 552, under Results, *Experiment 4*, in the second paragraph the word "variable" should be plural and the word "date" should be data."

On page 553, under Results, *Experiments 2, 3, and 4 Combined*, the word "man" in the second sentence should be "mean." In the second paragraph of that same section the following symbols should have been deleted: $(\overline{P}\text{-}\overline{A}/\overline{P}\%)$.

On page 554, under Results, *Experiment 6*, the first paragraph has a sentence reading as follows: "The total group 't' yields a mean difference of 0.63 second, of 2.14 which is significant beyond the 0.05 level." That sentence should read: The total group mean difference of 0.63 second yields a 't' of 2.14 which is significant beyond the 0.05 level." The last sentence in that same paragraph is also in error. It should read: "The 't' value for the 0.64% improvement shown by the total group was 2.49, with a corresponding two-tailed probability value beyond the 0.05 level."

EXAMINATIONS AND LICENSURE

MEDICAL SPECIALTY BOARDS

AMERICAN BOARD OF ANESTHESIOLOGY: *Written.* Various locations, July 8, 1960. Final date for filing application is January 8. Sec., Dr. Forrest E. Leffingwell, 217 Farmington Ave., Hartford 5, Conn.

AMERICAN BOARD OF DERMATOLOGY: *Written.* Several Cities, Oct. 5. *Oral.* Oklahoma City, Jan. 15-18, 1960. The final date for filing all applications was July 1, 1959. Sec., Dr. Beatrice M. Kesten, One Haven Ave., New York 32.

AMERICAN BOARD OF INTERNAL MEDICINE: *1959 Schedule—Written*, Oct. 19. Final date for filing application was May 1. *Oral.* For candidates on the West Coast, Portland, Ore., Sept. 9-12. Final date for filing application was March 1. *Oral.* For candidates on the East Coast, Nov. 6-7, 9-10. Final date for filing application was March 1. Sec.-Treas., Dr. William A. Werrell, One West Main St., Madison 3, Wis.

AMERICAN BOARD OF NEUROLOGICAL SURGERY: Examination given twice annually, in the spring and fall. In order to be eligible a candidate must have his application filed at least six months before the examination time. New Haven, Nov. 14-16. Sec., Dr. Donald D. Matson, 300 Longwood Ave., Boston, Mass.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: Applications for certificates, new and reopened, Part I, and requests for re-examination Part II are now being accepted. *Part I. Written.* Jan. 15, 1960. All candidates are urged to make such application at the earliest possible date. Deadline date for receipt of applications is August 1, 1959. No applications can be accepted after that date. Sec., Dr. Robert L. Faulkner, 2105 Adelbert Road, Cleveland 6, Ohio.

AMERICAN BOARD OF OPHTHALMOLOGY: *Oral.* St. Louis, Oct. 6-10. *Written.* January 1960 in various cities. Applications for the 1960 written examination must be filed before July 1. *Oral.* 1960, San Francisco, May; Chicago, October. Sec., Dr. Merrill J. King, Box 236, Cape Cottage Branch, Portland, Maine.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY: *Part II.* Chicago. Jan. 19-21, 1960. The deadline for the receipt of application is Aug. 15, 1959. Sec., Dr. Sam W. Banks, 116 South Michigan Ave., Chicago 3.

AMERICAN BOARD OF OTOLARYNGOLOGY: *Oral.* Chicago, Oct. 5-9. Final date for filing application was April 1. Sec., Dr. Dean M. Lierle, University Hospitals, Iowa City.

AMERICAN BOARD OF PATHOLOGY: New Orleans, Nov. 12-14. Final date for filing application is October 1. Sec., Dr. Edward B. Smith, Indiana University Medical Center, 1100 W. Michigan St., Indianapolis 7.

AMERICAN BOARD OF PATHOLOGY: *Examination in Forensic Pathology.* New Orleans, Nov. 13. Final date for filing application is October 1. Sec., Dr. Edward B. Smith, Indiana University Medical Center, 1100 W. Michigan St., Indianapolis 7.

AMERICAN BOARD OF PEDIATRICS: *Written.* January 1960. Exec. Sec., Dr. John McK. Mitchell, 6 Cushman Road, Rosemont, Pa.

AMERICAN BOARD OF PLASTIC SURGERY: *Oral and Written.* Miami, Fla., Oct. 15-17. Final date for submitting case reports is July 1. Corresponding Secretary, Miss Estelle E. Hillerich, 4647 Pershing Ave., St. Louis 8, Mo.

AMERICAN BOARD OF PROCTOLOGY: *Oral and Written.* Philadelphia, September. Final date for filing application was March 15. Sec., Dr. Stuart T. Ross, 520 Franklin Ave., Garden City, N. Y.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY: Chicago, Oct. 19-20; New York, Dec. 14-15; San Francisco, Mar. 14-15, 1960. Training credit for full time psychiatric and/or neurologic assignment in unapproved military programs or services between the dates of Jan. 1, 1950 and Jan. 1, 1954 was terminated on Jan. 1, 1959. Sec., Dr. David A. Boyd, 102-110 Second Ave. S. W., Rochester, Minn.

AMERICAN BOARD OF RADIOLOGY: *Examination.* Washington, Dec. 6-9. Deadline for filing application is July 1. Candidates examined in Diagnostic Roentgenology may expect to be examined in Physics. Obligatory examination in Nuclear Medicine has been postponed until after June 30, 1962 for those candidates being examined in Radiology or Therapeutic Radiology. Until that time the examination in Nuclear Medicine will be optional for those who wish to be examined in Radiology or Therapeutic Radiology. Sec., Dr. H. Dabney Kerr, Kahler Hotel Bldg., Rochester, Minn.

AMERICAN BOARD OF SURGERY: *Written* examinations (Part I) will be held on December 2, 1959 at various centers to be announced later. Candidates are urged to apply several months before completion of training requirements although the closing date for filing applications is August 1. Those completing training requirements after September 30 cannot be considered for the Part I examination in December of the same year. Sec., Dr. John B. Flick, 1617 Pennsylvania Blvd., Philadelphia 3.

BOARD OF THORACIC SURGERY: *Written.* Various centers throughout the country, September 1959. Final date for filing application was July 1. *Oral.* September. Final date for filing application was July 1. Sec., Dr. William M. Tuttle, 1151 Taylor Ave., Detroit 2, Mich.

AMERICAN BOARD OF UROLOGY: *Written.* Approximately 25 cities throughout the country, December 4, 1959. *Oral-Clinical* and *Examination in Pathology.* Chicago, February 1960. Final date for filing application is Sept. 1, 1959. Sec., Dr. William Niles Wishard, 30 Westwood Rd., Minneapolis 26, Minn.

GOVERNMENT SERVICES

ARMY

Personal.—Col. John W. Raulston, former deputy commander of Brooke Army Hospital, has taken command of the 67th Medical Group, and Col. John H. Taber has moved to the post of hospital deputy commander.

NAVY

Personal.—Rear Adm. Bruce E. Bradley, M. C., who has been deputy and assistant chief of the Bureau of Medicine and Surgery for the past four years, became commanding officer of the National Naval Medical Center, Bethesda, Md., in June. Rear Adm. Edward C. Kenney, M. C., is the new deputy and assistant chief of the bureau. At the Medical Center, Admiral Bradley will relieve Rear Adm. Thomas F. Cooper, M. C., who has retired.—–Rear Adm. Bartholomew W. Hogan, the surgeon general of the Navy, was appointed North American chairman of the Pan American Medical Association's section on military medicine.—–Capt. Donald R. Childs, M. C., was assigned to the Bureau of Medicine and Surgery as director of the publications division.—–Capt. Kenneth P. Bachman, M. C., retired after more than 16 years of active duty.—–Capt. George M. Bell, M. C., retired after 18 years of active duty.—–Capt. John H. Cox, M. C., retired after more than 19 years of active duty.

PUBLIC HEALTH SERVICE

Personal.—Dr. Floyd S. Daft, director of the National Institute of Arthritis and Metabolic Diseases, was named president-elect of the American Institute of Nutrition. He will succeed to the presidency on July 1, 1960. The American Institute of Nutrition is one of six scientific organizations comprising the Federation of American Societies for Experimental Biology.—–Dr. John C. Whitehorn, Henry Phipps professor and director of the department of psychiatry at the Johns Hopkins University School of Medicine, was appointed to the National Advisory Mental Health Council. He also served on the council from 1954 to 1958.—–Dr. John S. Lawrence, professor and chairman of the department of medicine at the University of California, Los Angeles, was appointed to the National Arthritis and Metabolic Diseases Council and will serve through Sept. 30, 1963.

Poliomyelitis.—Almost twice as many cases of paralytic poliomyelitis were reported in the first four months of 1959 as in the same period in 1958. Because a 45% increase in paralytic cases also occurred in 1958 over 1957, the surgeon general urged a renewed vaccination effort. In the first week of May, 19 new cases were reported as compared to only 7 for the same week in 1958. A total of 283 cases has been reported so far in 1959 compared with 147 for the same period last year. Vaccine shipments to fill domestic orders totaled 2,300,000 doses for the last week of April, a record high for 1959, indicating some increase in the numbers being vaccinated, but it is estimated that at least 50 million persons in the high risk group—those under 40 years of age—have not been fully vaccinated.

Insecticidal Fumes.—Willis Mathis and co-workers at the Savannah, Ga., laboratories of the Communicable Disease Center discovered what may prove to be an important new method of killing household mosquitoes. An unopened bag of insecticide was left inside a large laboratory where adult mosquitoes were confined for testing. Overnight, most of the mosquitoes died. Suspecting that fumes from the closed bag were responsible, the scientists decided to experiment. Their theory was confirmed. They found that the fumes killed mosquitoes even when the insecticide was enclosed in a paper bag with a polyethylene liner. In repeated experiments, the method worked even in rooms that were well ventilated. The most effective of the chemicals tested were malathion and DDVP, used in combination or separately. Both chemicals have been widely used against mosquitoes in recent years. More study will be required and specific techniques worked out before the method may be generally applied. Although the insecticides used are known to be relatively safe for human beings, further experiments must be conducted to determine that all possible human hazards are eliminated, but once the technique has been perfected and proved safe, it may greatly simplify control of mosquitoes.

Poliomyelitis Vaccine.—A committee of advisors reviewed the experience to date with the Salk poliomyelitis vaccine and concluded that groups vaccinated with the recommended series of three doses of vaccine have maintained a high degree of protection against poliomyelitis. Vaccine has been available to the public since 1955, and groups vaccinated over three years ago still maintain an appreciable protection against the disease. Studies of patients who had poliomyelitis in 1958 indicate that the probability of contracting the paralytic form has been reduced about 75% for those who had received the basic series of three injections of vaccine as compared with nonvaccinated persons. In some groups of children the probability of contracting the paralytic form has been reduced about 90% for those who had received the full basic course of three doses of poliomyelitis vaccine as compared to nonvaccinated children of the same age. Cases of paralytic poliomyelitis have occurred in persons who have received the basic course of injections of vaccine, but most cases of paralytic poliomyelitis occurring in 1958 were among unvaccinated persons.

In the light of present knowledge and experience the surgeon general's committee of advisors presents the following recommendations for poliomyelitis vaccination:

1. Completion of the basic series of three injections of Salk type vaccine is recommended for all persons under 40 years of age who have not yet been vaccinated or who have received fewer than three doses of vaccine. Vaccination of persons aged 40 and over can also be beneficial, but it is less urgent since poliomyelitis occurs less frequently in older persons. The recommended basic schedule for all persons, except young infants, is three doses of 1 ml. each as follows: an initial injection, a second injection four to six weeks after the first, and a third injection 7 to 12 months after the second dose.

2. A basic schedule of four injections, recommended for infants less than 6 months of age, consists of a series of three injections of 1 ml. each of the vaccine, spaced one month apart beginning before 6 months of age and as early as 2 months of age, followed by a fourth injection 7 to 12 months after the third dose. Poliomyelitis vaccine for infants and young children may be given as separate injections or in quadruple vaccines which combine poliomyelitis vaccine with diphtheria, pertussis, and tetanus vaccine. The schedule recommended by the manufacturer of such quadruple vaccines can be followed when this product is used. Infants under 6 months of age do not always develop an adequate antibody response from two initial injections so that the third primary injection appears desirable. Vaccination early in infancy is recommended, but complete information on optimal dosage schedules will require further experience with the separate and quadruple vaccines.

3. It is recommended that a booster dose of 1 ml. of poliomyelitis vaccine be given to persons under 40 years of age who have completed the basic series of three doses at least one year previously and especially if several years have elapsed since completion of the basic series of injections. Such a booster dose is expected to increase antibody titers in persons in whom the antibody levels have fallen or in whom the initial antibody response was weak, thereby providing possible added protection against poliomyelitis.

4. A booster dose of 1 ml. of poliomyelitis vaccine for vaccinated persons is especially indicated for persons entering situations or traveling into areas where the incidence of poliomyelitis is high, for example, (*a*) at the beginning of local epidemics of poliomyelitis—emergency booster doses as early as one month after the previous dose of vaccine, regardless of the number of previous doses; (*b*) when preschool children are to enter school; (*c*) for pregnant women prior to the poliomyelitis season—for the vaccine not only provides added protection against the disease for the mother but also provides a passive immunity to the unborn baby; and (*d*) for persons traveling into areas where sanitation may be poor or poliomyelitis is known to be present.

These recommendations have been drawn up with the advice of Col. Donald M. Alderson, U. S. A. F., M. C., assistant for professional services, office of the assistant secretary of defense (health and medical); Dr. Gordon Brown, professor of epidemiology, University of Michigan School of Public Health; Lt. Col. Joseph W. Cooch, chief, Communicable Disease Branch, Department of the Army; Dr. Edward C. Curnen, chairman, Committee on the Control of Infectious Diseases, American Academy of Pediatrics; Dr. Geoffrey Edsall, chairman, Committee on Immunization of the Armed Forces Epidemiology Board; Dr. Hollis S. Ingraham, first deputy commissioner, New York State Health Department; Dr. Cyrus Maxwell, Washington Medical Liaison, American Medical Association; Dr. Andrew C. Offutt, Indiana health commissioner, Dr. James C. Overall, president of the American Academy of Pediatrics; Dr. Julian P. Price, Chairman of the Poliomyelitis Committee of the American Medical Association; Dr. Thomas M. Rivers, vice-president–medical affairs, the National Foundation; Dr. Jonas Salk, professor of experimental medicine and director of Virus Research Laboratory, School of Medicine, University of Pittsburgh; and a number of officials from the Public Health Service.

C.; Medical College of the State of South Carolina, Charleston, 1911; veteran of World War I; formerly member of the county board of education and for many years served as a surgeon for the Seaboard Airline Railway; on the staff of the Hampton County Hospital; died April 15, aged 71.

Prentice, Arthur Dudley, San Francisco; Cooper Medical College, San Francisco, 1895; retired after 32 years as an epidemiologist with city department of health; veteran of the Spanish-American War; died in the Veterans Administration Hospital April 19, aged 89.

Prince, Arthur, Eastchester, N. Y.; University and Bellevue Hospital Medical College, New York City, 1930; veteran of World War II; served on the staffs of the St. John's Riverside Hospital in Yonkers and the New Rochelle (N. Y.) Hospital; member of the staff of the Mount Vernon (N. Y.) Hospital; died April 12, aged 57.

Reps, Dewey H. Ⓜ Louisville, Ky.; University of Cincinnati College of Medicine, 1925; veteran of World Wars I and II; member of the American Academy of Occupational Medicine and the Industrial Medical Association; assistant medical director of the E. I. Dupont de Nemours & Company's neoprene plant; died in St. Joseph Infirmary April 11, aged 63.

Rieger, Herman Paul Ⓜ Nashville, Tenn.; Baltimore Medical College, 1907; veteran of World War I; on the staff of the Baptist Hospital; died April 16, aged 74.

Ross, Paul Edward Ⓜ Ottawa, Ill.; University of Chicago, The School of Medicine, 1937; member of the American Academy of General Practice; associated with St. Mary's Hospital in La Salle, St. Margaret's Hospital in Spring Valley, and Perry Memorial Hospital in Princeton; on the staff of the Ryburn Memorial Hospital; died in St. Francis Hospital, Peoria, April 13, aged 53.

Ryan, Nicholas Henry, Brooklyn; Fordham University School of Medicine, New York City, 1918; fellow of the American College of Surgeons; past-president of the Kings County Medical Society; taught at the Long Island College of Medicine; on the staff of the Kings County Hospital; secretary of Ryan Ready Mixed Concrete Corporation; died March 27, aged 71.

Schrade, Anna Magdalene Ⓜ Erie, Pa.; Woman's Medical College of Pennsylvania, Philadelphia, 1902; died March 4, aged 83.

Sharpless, Isaac Ⓜ Rosemont, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1940; veteran of World War II; served as physician of the Philadelphia Ramblers, ice hockey team, Bryn Mawr College, and the Shipley School; member of the executive committee and on the staff of the Bryn Mawr (Pa.) Hospital, where he died April 26, aged 47.

Shelley, Penrose Herr, Port Royal, Pa.; Jefferson Medical College of Philadelphia, 1911; past-president of the Mifflin–Juniata Counties Medical Society; served as school director; veteran of World War I; president of the Port Royal National Bank; on the courtesy staff of Lewistown (Pa.) Hospital; past-president of the Rotary Club; died April 11, aged 73.

Smith, Clifford Addison, Clarington, Ohio; Baltimore Medical College, 1909; died in the City Hospital, Bellaire, April 9, aged 82.

Speer, William Louis Ⓜ Osawatomie, Kan.; Jefferson Medical College of Philadelphia, 1912; member of the American Academy of General Practice; veteran of World War I; in 1945 named Miami county coroner; on the staff of the Miami County Hospital; died April 12, aged 79.

Springer, Ernest Ⓜ Boston; Tufts College Medical School, Boston, 1921; fellow of the International College of Surgeons; member of the American College of Gastroenterology; for many years on the staff of the Massachusetts Memorial Hospitals; on the staff of the Allerton Hospital in Brookline, where he died April 18, aged 60.

Stiles, Francis Augustus Ⓜ Elizabethtown, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1900; died in the Masonic Homes Hospital March 17, aged 83.

Stoelzle, Joseph Daniel Ⓜ Kirkwood, Mo.; St. Louis University School of Medicine, 1920; died Feb. 9, aged 62.

Sullivan, Ralph Charles Ⓜ Oak Park, Ill.; Rush Medical College, Chicago, 1912; fellow of the International College of Surgeons and the American College of Surgeons; on the staff of the Oak Park Hospital, where he died April 29, aged 72.

Swart, William James Ⓜ Schenectady, N. Y.; Albany (N. Y.) Medical College, 1898; formerly a Presbyterian missionary in Siam; for many years physician in the county schools; on the courtesy staff of St. Clare's and Ellis hospitals; died April 6, aged 85.

Swift, Albert George Ⓜ Syracuse, N. Y.; Syracuse University College of Medicine, 1902; specialist certified by the American Board of Surgery; fellow of the American College of Surgeons; professor emeritus of surgery at his alma mater; associated with St. Joseph Hospital and University Hospital of the Good Shepherd, where he died April 22, aged 79.

Troupa, Alburt Burton Ⓜ Princeton, Ill.; Chicago College of Medicine and Surgery, 1917; past-president of the Bureau County Medical Society; interned at the Illinois Charitable Eye and Ear Infirmary in Chicago; past-president of the Lions Club; on the staff of the Perry Memorial Hospital, where he died April 1, aged 77.

Willmott, Ashby Carlisle Ⓜ Altadena, Calif.; Kentucky University Medical Department, Louisville, 1901; veteran of World War I; retired in 1947 as surgeon for the Pacific Electric Railway; died in Pasadena April 8, aged 81.

Witt, Dea Cleveland, High Springs, Fla.; University of Tennessee Medical Department, Nashville, Tenn., 1909; served as director of the Bay County health unit; died April 5, aged 74.

Streptococcic and Nonstreptococcic Sore Throat.—Of 81 patients with sore throat this symptom was due to undifferentiated acute respiratory diseases in 36, to streptococci in 34, to mononucleosis in 6, to adenovirus in 4, and to Vincent's infection in 1, as reported by V. Esmann (*Acta med. scandinav.* 163:265-276, 1959). As streptococcic and nonstreptococcic sore throats could not be differentiated on the basis of clinical observations, routine cultures of pharyngeal material for the isolation of beta hemolytic streptococci were made from these patients. An increase in antistreptolysin titer (AST) was found to be a significant sign of streptococcic sore throat, when this increase amounted to 100% of the initial AST, and when the titer in the convalescent phase exceeded 100. An increase in the AST was found to be a significant sign of streptococcic sore throat when the titer in the convalescent phase exceeded 9,000. A significant increase in one or both antibodies was revealed in 50 of the patients. Since the differences between streptococcic and nonstreptococcic sore throat were of a quantitative rather than of a qualitative character, it was difficult if not impossible to decide which of the two types existed in a given patient. Accordingly, a bacteriological study of the pharyngeal flora was important not only in order to secure the diagnosis but also in therapeutic considerations, since penicillin treatment is ineffective against virus infections and therefore contraindicated.

Acute Renal Failure.—A. P. Skouby (*Acta med. scandinav.* 163:277-287, 1959) stated that our knowledge of the underlying mechanisms of acute renal failure was meager and the results of treatment poor. He reported on a series of 56 consecutive patients with acute anuria believed to be due to renal shock. This condition was eventually demonstrated in 37. Limb lead electrocardiograms were found to be of value for differentiating between acute renal failure and uremia due to chronic renal disorders. Apart from conventional methods levarterenol and hydrocortisone were used in pharmacological amounts in selected patients. No secondary actions of levarterenol were detected, and in patients under treatment for one or several days the diuresis increased greatly during the administration.

Hydrocortisone might be of value in the treatment of renal failure in patients with severe primary disorders. No ill-effects were demonstrated. The therapeutic effects obtained depended largely on the basic disorders. In the present series renal shock in most cases appeared as a complication of a severe illness and not as an isolated renal disorder. By treatment of shock and infection the condition of the patients often improved and with the further aid of procedures limiting the influence of renal failure a number of patients recovered. The improvement was often transient, however, and the patients almost always died from the primary disorder, seldom from uremia. Therefore better results might be obtained only by intensified treatment of the basic illness as soon as possible and at least as effectively as with an analogous case in which uremia was not present. Simultaneously, or when the basic illness is under control, procedures curtailing the influence of renal failure might be performed.

Antigravity Suit in Neurosurgery.—P. Freuchen (*Acta anaesth. scandinav.* 3:17-23, 1959) reported that some neurosurgeons preferred to perform certain operations with the patient in a sitting position but that owing to the hydrostatic pressure and the obstruction of the regulation of the circulation this position caused pooling of blood in the lower extremities. To meet these difficulties the author used an antigravity (anti-g) suit which, when inflated with air, exerted a pressure on the patient's legs and lower part of the abdomen. A comparison was made between the effect of the anti-g suit on 14 patients and 14 patients previously operated on for similar disorders in the sitting position with their lower extremities wrapped in elastic or flannel bandages. The use of the anti-g suit made it possible to maintain constant values for pulse rate and blood pressure and thereby maintained optimum conditions for the circulation.

FINLAND

Antibiotics and Immunity.—E. Klemola (*Nord. med.* 61:464-468 [March 19] 1959) commented that in assessing the value of antibiotic treatment a negative factor to be considered was that immunity might be delayed or reduced. It has been shown in animal experiments that early antibiotic treatment in pneumococcic infections and tularemia could reduce immunity. In man recurrences are common in patients with typhoid and paratyphoid treated with chloramphenicol when the treatment is

---

The items in these letters are contributed by regular correspondents in the various foreign countries.

stopped too early, as it takes time for immunity to develop. The most important problem concerns the infections caused by beta hemolytic streptococci.

Although penicillin treatment delays and weakens the rise in the antistreptolysin titer (AST), no definite conclusions can be drawn from the AST changes as regards immunity. The fact that despite a good primary effect in scarlatina treated with tetracyclines many bacterial complications caused by the original streptococcic types occur in the weeks after the cessation of treatment could be partly traced to the delayed development of type-specific antibacterial immunity. Scarlatina is a good example of a disease in which antibiotics may delay antitoxic immunity, in this case against an erythrogenic toxin of streptococci. Late second attacks occurring more than three months after the original disease are no longer uncommon. Of 9,400 patients in Stockholm treated with penicillin and with a mean observation period of 2½ years 4.5% had second attacks. Before penicillin was used, and for a period of 10 years, only 1.2% of the patients suffered a second attack.

Of 7,837 patients in Helsinki treated between 1947 and 1956 for a mean observation period of 6½ years, 501 patients or 6.4% had a second attack, of which 1.4% occurred within three months of the first attack and 5% later. The number of cases in which a person acquired scarlatina more than twice is greater than before. In considering the causes of second attacks the moment at which antibiotic treatment is started, the time elapsed after the initial disease, and the degree of severity of the new infection should be taken into account. Although immunity will be reduced if treatment is started early, it is in general desirable to do so because, as stated by the author, the physician concerned cannot take the responsibility for the complications that may arise, all the more as the second attacks are in most cases mild and easy to treat. Except in streptococcic infections the reduction of immunity by antibiotic therapy is probably of no great practical significance. The author concluded that with the discovery of new antibiotics the future situation might be different with regard to both the individual and the community.

GERMANY

Myocarditis and Foot-and-Mouth Disease.—A. Lübke (*Arch. path. Anat.* 332:170, 1959) stated that the hematogenously disseminated foot-and-mouth disease virus penetrates into the myocardial fibrils. The rate and the extent of multiplication of the virus differ from patient to patient and depend on the virus strain. All fibrils are never involved. An abortive increase in the virus may remain optically invisible or may cause only a reversible metabolic disturbance, i. e., fatty change. With a further multiplication of the virus the so-called clumpy degeneration occurs. This usually stops at the intercalated disk. The necrotic fibrils remain rich in virus. Independent of the duration of the infection the virus content of the heart remains high as long as hyalinized muscle fibers or fiber particles are present.

As the necrotic fibers are removed through autolysis and heterolysis the fused particles of virus and fibrillar substance may escape into the circulation. The local neutrophilic reaction is indirectly induced and has little effect on the necrosis. The granulocytes produce no apparent reduction of the virus. In some patients a calcification of the dead fibrils results, but seemingly this does not effect the virus content. The mesenchymal reaction leads finally to a complete replacement of the necrotic fibers (myolysis). During this process the virus disappears from the heart muscle. In the stage of acute inflammatory myocarditis the heart is virus-free, regardless of the duration of the infection. Apparently the macrophages are able to remove not only the destroyed fibrils but also the engulfed virus enzymatically. Seven days after the infection the mesenchymal tissue proliferation begins. The small inflammatory foci ultimately disappear and the large foci heal, leaving scars.

Pulmonary Hypertension.—Esch and Thurn of the University of Bonn (*Fortschr. Geb. Röntgenstrahlen* 90:434, 1959) studied the significance of the following radiologic signs: (1) prominence of the main pulmonary artery segment, (2) widening of the central pulmonary arteries, (3) narrowing of the peripheral pulmonary arteries, and (4) abrupt narrowing at the junction between widened lobar arteries and narrowed segmental arteries. Apart from increased pressure, prominence of the main pulmonary artery segment and dilation of the lobar arteries may be caused by increased blood flow through the lungs. Typical differences in pulsatory behavior were observed. Increased pulmonary blood flow was frequently associated with dilated peripheral arteries. Their behavior under these circumstances was not a reliable radiologic index of the pressure relationships in the lungs. The abrupt change in caliber was the only reliable sign of pulmonary hypertension, even in patients with increased pulmonary blood flow. There was no correlation between the gradual development of the radiologic signs and the height of the pulmonary pressure, although the diagnosis of probable pulmonary hypertension could generally be made on the basis of an ordinary roentgenogram.

Sarcomas.—E. Zeitler (*Strahlentherapie* 108:428, 1959) studied a series of 636 patients with sarcoma and compared the results of purely surgical, radiologic, and combined treatment for the entire series. The five-year survival rate was 30%. The results were better than average in patients with osteosarcoma, fibrosarcoma, and spindle cell sarcoma. The best results were found in those with myosarcoma of the uterus and melanosarcoma of the eye who received purely surgical or combined surgical and radiologic treatment. The three-year survival rate was 50% in these patients. The prognosis was much worse in those with reticulum cell sarcoma, granular cell sarcoma, and lymphosarcoma. The highest three-year survival rate (32.2%), not considering the type of sarcoma, was found in those who received combined surgical and radiologic treatment.

Spleen Cell Suspension for Marrow Damage.—Immediately after whole-body irradiation of inbred rats with 800 rep by high-energy electrons the animals were given an intravenous injection of 100 to 200 x 10,000,000 spleen cells of healthy animals of the same breed, by Thom and Hübner of the University of Heidelberg (*Strahlentherapie* 108:371, 1959). As compared with untreated animals the regeneration of the damaged marrow was more rapid qualitatively and quantitatively. The initial phase of damage was not changed. The first regenerations of the marrow of the treated animals were observed on the third day after irradiation. A complete restitution was observed within 14 days in the treated as compared with 21 days in the untreated animals.

Chronic Leukemia.—The effect of x-ray therapy on survival and duration of illness was studied at the University of Bonn in 132 patients with chronic granulocytic or lymphocytic leukemia by G. Oberhoffer and co-workers (*Strahlentherapie* 108:325, 1959). The duration of illness was not influenced by early or late x-ray therapy. There was no difference in the prognosis in chronic granulocytic or lymphocytic leukemia. The survival time and duration of illness in chronic leukemia were not changed by x-ray therapy, but symptomatic relief was obtained for a short time. Therapy with blood transfusions, antibiotics, cytostatics, and cortisone derivatives also did not change the survival time or duration of chronic leukemia.

Leukocytes and Organisms in Urine.—W. Rupp (*Med. klin.*, vol. 54, 1959) studied the leukocytic and bacterial content of the urine of 690 children (130 boys and 560 girls) with healthy kidneys. The genitals were cleansed with a 0.1% solution of benzalkonium chloride, and 1 or 2 ml. of urine was collected through a sterile catheter. Another sample was then collected in a second sterile test tube, and a bacteriological examination was made within 30 minutes. The leukocyte count was made from the first sample. None of the samples contained albumin. The micro-organisms were counted according to the method of Sanford and the species differentiated by routine bacteriological methods. Between 0 and 10 leukocytes per cubic millimeter were found in samples from 97% of the boys and 93% of the girls, but there was no significant difference between samples from single and repeated catheterization. No micro-organisms were detected in samples from 47.5% of the boys and 37.5% of the girls in single determinations.

In another third of the samples less than 10 micro-organisms were found per milliliter of urine, while more than 10 per milliliter were never found on a single examination. There was no striking difference, on single and repeated catheterization, in the number of micro-organisms detected in the urine of boys or girls. Staphylococcus albus was found in about 50% of all bacteria-containing samples from boys. In 25% of the samples Streptococcus faecalis, followed by Escherichia coli, alpha hemolytic streptococci, Staph. aureus and Proteus vulgaris, was detected. These findings remained essentially unchanged even when a great number of urine samples were examined. In girls the occurrence of only one species of bacteria was not so frequent, and on repeated catheterization beta hemolytic streptococci were more often found than alpha hemolytic strains. Esch. coli and Staph. aureus were definitely found more often in girls than in boys. Staph. albus and alpha hemolytic streptococci were most frequently present in mixed cultures with less than 10 micro-organisms per milliliter, while S. faecalis, Staph. albus, and Esch. coli were more predominant in ranges with more than 10 micro-organisms per milliliter.

These tests confirmed the results obtained by others who had reported a standard number of 0 to 10 leukocytes per milliliter in catheterized and noncatheterized specimens from girls, and this also explained why the slightly enhanced leukocyturia associated with urinary tract infections, especially chronic pyelonephritis, is often not taken seriously and therefore disregarded as a pathological criterion. If the technique is properly employed there should be no irritative leukocyturia even on repeated catheterization. Of the boys examined only once 81% had less than 10 micro-organisms per milliliter of urine, while on repeated examination the percentage rose to 85. The corresponding percentages in girls were 71 and 74.5. In this range Staph. albus was most frequent, followed by alpha hemolytic streptococci and S. faecalis. If there were between 10 and 1,000 organisms per milliliter of urine, Esch. coli was most frequent in girls, whereas Staph. albus was predominant in boys. We may consider 1,000 to 10,000 organisms per milliliter of urine to be the maximum number normally present in catheterized urine specimens from children, and in any case if figures higher than 1,000 per milliliter are reported another specimen should be examined to exclude the possibility of an infection being present.

Lead Poisonings.—J. Lange and co-workers (*Med. klin.*, vol. 54, 1959) reported that as a result of better care and protective measures lead poisoning in the printing trade is no longer common. Lead poisoning now occurs mostly in workmen making dyestuffs and storage batteries. The acute disease is easy to diagnose, but proper treatment is important. Previous attempts to eliminate the lead from the body with potassium iodide, ammonium chloride, calcium salts, dimercaprol, and dihydrotachysterol proved unsatisfactory. These measures aimed at converting the heavy metal into an innocuous depot form. Treatment with edathamel calcium-disodium (EDTA) relieves the abdominal pain of lead poisoning within a few days without producing side-effects. EDTA was given to five persons who had a history of lead poisonings. In two of these lead was excreted from the urine, although they had not been in contact with lead for three years. Controls trials were carried out on six healthy volunteers, and even in these a slightly increased urinary excretion of lead was observed, which indicated that lead intake may occur in persons with no professional contact with this element. Although the drug used binds and thus eliminates not only lead but also magnesium, copper, and iron, this did not result in any undue depletion of the body's essential stocks of these substances. It was further shown that lead anemias in patients treated with EDTA improved without additional iron therapy.

Mastocytosis.—D. Remy of Hamburg, at the meeting of the German Society of Internal Medicine at Wiesbaden in April, stated that urticaria pigmentosa can no longer be considered an isolated skin disease. Although it is characterized by cutaneous symptoms, it affects other organs. It consists in mast cell infiltrations of the subcutis and mast cell proliferation in the reticuloendothelial system, especially the spleen, liver, and bone marrow. In some patients the cutaneous symptoms predominated but in others they were absent, although an accumulation of mast cells in the reticuloendothelial system could be demonstrated. The increased release of histamine caused urticaria in some patients and in others severe circulatory collapse with an extreme drop in blood pressure, usually preceded by an erythematous flush. Vomiting and fever might occur at the same time. In these patients remissions alternated with severe circulatory crises.

Further symptoms are characterized by hyperheparinemia, which leads to an increased tendency to bleeding, shifts of the lipoproteins of blood serum with a marked lowering of cholesterol and phospholipids, and deviations of the lipid electrophoretic pattern. Elevated excretion of decomposition products of serotonin was not observed in the author's series although this has been described by others. Other signs included skeletal changes (especially osteosclerosis), gastric hyperacidity and occasionally ulcers partly due to hyperhistaminemia, and motor and secretory disturbances of the small intestine. The disease bears a nosological relationship to mast cell leukemias, although the peripheral basophil count is usually not increased in the latter. It appears justified, however, to speak of a mast cell leukosis. A close relationship to plasmocytoma and the lymphoreticuloses seems to exist, and mixed forms have been occasionally observed.

Nicotinic Acid Amide Metabolism.—At the same meeting N. Gerlich reported that he had treated a series of 504 patients who had internal tumors with bis-ethylenimino-benzoquinone and tris-ethylenimino-benzoquinone. The limitations of such cytostatic treatment were set not only by the toxic leukopenia and thrombocytopenia that developed with adequate doses but by also general symptoms appearing and growing progressively worse with prolonged therapy (atrophy of nails and of gastrointestinal mucosa, dryness and scaliness of the skin, and depression). The leukocyte count remained at about 3,000 per cubic millimeter. The clinical symptoms corresponded to those of hypovitaminosis.

An increasing deprivation of nicotinic acid amide developed during prolonged treatment. Recent findings by Holzer and co-workers suggested that the ethylenimino compounds lowered the diphosphopyridine nucleotide (DPN) concentration. These cytostatic products are capable of alkylating nicotinic acid amide as pyridine nitrogen. Nicotinic acid amide and also nicotinic acid can therefore compensate the effect of ethylenimino-quinones. The experimental hypovitaminosis produced by prolonged cytostatic treatment causes death when not counteracted. The reduction of DPN concentration exerts no effects either in the tumor itself or throughout the body.

INDIA

Serum Proteins in Gestoses.—M. K. K. Menon and co-workers (*Journal of Obstetrics and Gynecology of India,* vol. 9, March, 1959) estimated the serum protein levels in patients with preeclampsia and eclampsia and in the babies born to these mothers. Estimations were also made to determine whether there were any variations in these values after delivery and the establishment of lactation. Patients with preeclampsia only 34 to 40 weeks pregnant and showing edema, albuminuria, and hypertension were included in the study. They were further divided into those with grade A (mild) and grade B (severe) conditions. Only antepartum eclamptic patients were included. The first sample of blood was collected in the acute phase of the disease, and further samples were taken 48 to 96 hours after delivery. There were 47 patients with preeclampsia grade A, 9 with grade B, and 42 with eclampsia.

Estimations of serum protein levels were made in 17 babies of mothers with grade A and in 7 of mothers with grade B preeclampsia, and in 17 of mothers with eclampsia.

There was a significant drop in the total serum protein levels in all the toxemic patients as compared to the values in normal pregnant patients. The fall in the albumin fraction was not statistically significant in patients with grade B preeclampsia and in eclampsia but it was markedly significant in those with grade A preeclampsia. Even more significant was the reduction in the globulin fraction, the beta and gamma globulins showing a greater fall than alpha-1 and alpha-2 fractions. Thus the fall in total serum proteins was due to a fall in both the albumin and globulin fractions, the reduction being more significant in the latter. The variations in the values of serum proteins in patients with grade B preeclampsia and eclampsia were almost identical but were statistically different from those observed in patients with grade A preeclampsia. The total serum protein level and its fractions showed a higher value in grade B preeclamptic and eclamptic patients as compared to grade A preeclamptic patients, probably due to hemoconcentration which was believed to exist in these patients.

The values were, however, lower than those obtained in normal pregnant patients. The variations in serum protein levels observed 48 and 96 hours after delivery were similar to those after normal pregnancy. Thus the albumin showed a fall after delivery but slowly increased at 96 hours. The mean value of globulin slowly increased soon after the birth of the child and more after 96 hours. The total protein level showed a small drop at 48 hours, but by 96 hours the values had reached and passed the preparturient level. The serum protein levels in babies born to toxemic mothers reflected the same variations from normal as were observed in the mothers themselves. Thus the total protein levels and albumin and globulin fractions were reduced in babies born to mothers with preeclampsia and eclampsia, the fall in the beta and gamma globulin values being statistically significant.

Dysfunctional Uterine Bleeding.—Shah and Dave (*Journal of Obstetrics and Gynecology of India*, vol. 9, March, 1959) defined dysfunctional uterine bleeding as abnormal bleeding in the absence of a neoplastic, inflammatory, or chorionic lesion. It includes conditions of the endometrium resulting from disturbed endocrine function and others in which no abnormality is revealed by ordinary histological examination. A series of 35 patients with this condition between the ages of 13 and 39 years were studied, and of these 5 were later found to have an organic lesion of the uterus. The endometrium was studied in 27 of the remaining 30 patients. No single endometrial pattern was associated with dysfunctional uterine bleeding, although in most patients the changes in the endometrium conformed to those of the proliferative phase or of hyperplasia cystica glandulosa. Thus in this study 15 patients showed proliferative changes, 7 showed hyperplasia, and 5 showed typical secretory phase. In most of the patients a single endometrial biopsy specimen and vaginal smear were obtained prior to treatment. A differential count was made from 200 to 300 normal squamous epithelial cells of each vaginal smear and the percentage of cornified and basal or parabasal cells determined. If there was a cervical erosion, or an infection of the cervix or vagina existed, the determinations from these patients were dropped from the study.

Androgen therapy was started if the vaginal cytological findings were suggestive of high estrogen activity. The dosage was 25 mg. of the hormone daily for three days and later every second or third day. Smears were repeated after administration of 100, 150, 200, and 250 mg. and at the end of treatment. Endometrial biopsy specimens were also taken if possible. The total dosage usually ranged between 150 and 250 mg., spread over two to four weeks. Once bleeding stopped ethinyl estradiol orally and progestrone parenterally were given in a cyclic fashion for 5 to 12 consecutive cycles. Androgen therapy was advocated in patients who had 40% or more of cornified cells in their vaginal smears. This was indicated in 16 of the 30 patients. When properly guided by vaginal smear examination, this therapy was found to give beneficial results in most such patients.

After about 100 mg. of testosterone was given the effects of estrogen neutralization were observed by reduction in the number of cornified cells and a proportionate increase in precornified or intermediate cells. With further administration there was greater reduction in the cornified cells and the appearance of basal cells. The dosage of androgen required in different patients for physiological neutralization of estrogen was variable. In the dosage employed in this study it not only helped in stopping the bleeding but also probably helped in normalizing the basic dysfunction in some patients with anovulatory bleeding. Although vaginal cytological study helps in deciding the hormonal therapy, microscopic examination of the endometrium cannot be omitted entirely as organic lesions of the uterine mucosa might thus be missed. Tuberculosis of the endometrium was responsible for 3 of the 35 cases in this study which would have remained undiagnosed if no endometrial biopsy had been performed.

Cholera.—According to a report issued by the World Health Organization 1958 was a bad year for cholera. The number of cases which occurred in Asia (about 93,000) was the highest recorded since 1953, when the disease struck 242,000 people.

Epidemics occurred last year in India, Pakistan, Thailand, and Nepal. The worst epidemic was in the lower Ganges valley in eastern Pakistan, where 20% of all cholera cases for the year were reported. Several districts in India were also severely hit, and there were 4,895 cases with 1,765 deaths in Calcutta alone.

Malignant Hypertension.—Pinto and Shah (*Journal of the Association of Physicians of India,* vol. 7, March, 1959) studied a series of 22 patients with grade 4 hypertensive encephalopathy. The onset was acute in 6 patients and gradual in 16, some of them learning that they had hypertension only after they came to hospital. Most of the patients were between 20 and 40 years of age and none was over 50. The systolic pressures varied between 270 and 180 mm. Hg and the diastolic pressures between 194 and 94 mm. Hg. Six patients received no hypotensive drugs, 13 were treated with ganglion blocking agents, and 3 were given hypotensive agents. None was treated by Kempner's rice diet alone, but one who did not respond to large doses of pentolinium compound showed a significant fall in blood pressure after being put on this diet for 14 days and then given small parenteral doses of pentolinium.

The results indicated that a combination of pentolinium compounds administered subcutaneously and Rauwolfia derivatives given orally, preceded by two weeks of the rice diet, was the most effective treatment, while oral administration of mecamylamine and Rauwolfia derivatives was the most convenient form of treatment. The use of ganglion blocking agents helped to prolong the life of patients with malignant hypertension. Thus, while only 1 of the 6 untreated patients survived, 5 of the 13 treated with ganglion blocking agents were discharged with a marked reduction in both systolic and diastolic blood pressures and complete relief from distressing symptoms.

The progress of two patients was followed for two years, and they were still normotensive when last seen. Of the patients treated with ganglion blocking agents seven showed marked subjective and objective improvement, three showed a moderate improvement, and in three there was no improvement. Complete relief of symptoms was obtained in those in whom the blood pressure showed a marked fall. The symptoms were not relieved in those who responded with moderate or poor fall in blood pressure. The retinopathy improved in 3 of the 22 patients with improvement in vision.

In the same issue M. J. Shah and co-workers reported a series of 14 patients with hypertensive encephalopathy, the incidence of which appears to be declining although that of hypertension is increasing. Therapy with intravenously given sucrose was used as a dehydrating measure with no adverse effects in five patients, and 50% dextrose solution was given to 7. Magnesium sulfate solution was given to 11 patients per rectum. Lumbar puncture was performed on only one. Ganglion blocking agents were given to five and Rauwolfia alkaloids to four. Of the 14 patients 5 were treated with dehydrating measures alone, and of these 4 died; 9 received antihypertensive drugs in addition to dehydrating measures, and of these only one died. One patient showed a precipitous and uncontrollable fall of blood pressure, after a parenteral dose of pentolinium tartrate, which proved fatal; one patient who was given hexamethonium developed a residual permanent hemiplegia.

Blood Sugar Levels and Glycosuria.—Sathe and Ajgaonkar (*Journal of the Association of Physicians of India,* vol. 7, March, 1959) tried to correlate blood sugar levels with renal threshold and the degree of glycosuria and assess the value of these findings in the interpretation of the status of diabetes, in a series of 34 diabetics whose ages varied between 25 and 75 years. The 24-hour urinary volume gave no indication of the severity of diabetes; 24-hour urinary sugar excretion levels, although useful in assessing the progress of the disease, were not a reliable guide because the renal threshold varied during treatment. Estimation of the sugar level in fasting urine samples was also misleading. Urine passed two hours after a full meal was the only fairly reliable guide, provided the renal threshold was not too high. The severity of diabetes could not be assessed from the fasting blood sugar levels. The authors concluded that a glucose tolerance test should be made whenever possible to assess the diabetic state and elicit the renal threshold.

Diethylcarbamazine and Tropical Eosinophilia.—S. S. Misra and co-workers (*Journal of the Indian Medical Association,* vol. 32, March 16, 1959) treated 40 patients who had tropical eosinophilia with diethylcarbamazine. The absolute eosinophil counts were over 4,000 per cubic millimeter in these patients; stool and sputum specimens were negative for any parasitic infection; the night blood film was negative for Microfilaria bancrofti on three consecutive occasions; and radiologically most of them showed the findings of eosinophilic lung disease. Dry cough, dyspnea, and wheezing were present in all. Sternal marrow smears were made from all patients. The total and differential leukocyte counts were repeated after four days of oral therapy with the drug. Subsequently leukocyte counts were made as frequently as necessary until they came down to normal. An absolute eosinophil count and sternal marrow smear were repeated at this stage. For oral therapy most adults received 12 tablets of 50 mg. each per day in 3 or 4 divided doses, while children were given 8 or 9 tablets in divided doses. Of the eight patients treated parenterally the first four patients were given 800 mg. of the drug intramuscularly and the rest were given three or four injections of 400 mg. each at intervals of three to five days.

Of the 32 patients receiving oral therapy 31 were cured. By the fourth day there was either complete or partial relief. Symptomatic relief was almost always prompt. These 31 patients had a complete remission of physical signs at the end of therapy. The eosinophil counts showed a definite fall within four days in 16 patients and in the rest the count came down gradually. The time taken for complete remission of eosinophilia varied widely. Sternal puncture was done before starting and after termination of therapy in 14 patients. In all it showed hyperplasia and predominance of immature and mature eosinophils at the start of the therapy, while sternal smears after therapy showed only a few eosinophils, most of which were mature. The maximum duration of therapy was 30 days. Most patients required treatment for 10 to 16 days. There was an almost complete lack of toxicity, most of the patients tolerating the drug well. Some had anorexia and nausea. There was no correlation between the duration of illness and the length of required therapy.

Two patients who had earlier proved resistant to arsenic were given this drug with gratifying results. The quick symptomatic relief without the initial symptomatic aggravation often produced by arsenic, absence of relapse, ease of administration, and shorter duration of therapy as compared with arsenical treatment were some of the advantages. The intramuscular therapy with this drug, however, proved disappointing. Nausea, vomiting and drowsiness occurred in all patients. Some had giddiness, dryness of the mouth, and itching all over the body. One developed such marked respiratory depression that he had to be kept in an iron lung for several days. The symptoms and signs were aggravated, and there was an increase in the eosinophil count. Of the four patients receiving 800 mg. by injection only one was cured, while toxic reactions were seen in all. In those who received three or four injections of 400 mg. there was only symptomatic relief with a decrease in blood count, but the blood picture did not return to normal. Six of the eight patients who received parenteral therapy later responded to oral doses of the drug, and one was cured with arsenic.

Medical Teaching.—In his presidential address to the Association of Physicians of India Dr. Bhatia made a strong plea for raising the salaries of the teaching staffs of medical colleges. He said that medical colleges should have some full-time teachers, but the faculties should be supplemented by paid part-time and honorary teachers. He saw no reason why the top medical teachers should not be paid the same emoluments as are given to judges, civil service secretaries, or professors of engineering. The union government has issued a circular to the state governments directing them to maintain nonpracticing teaching posts on very low salaries. If the government's directive is carried out, further deterioration in the standards of medical education will occur. It is essential that some of the teaching be given by teachers conversant with treatment in the home environment—the type of treatment most of the graduates will have to give when they start their practice. The speaker suggested that university examinations be gradually dispensed with and students be given credit for day-to-day work.

Experimental Tuberculosis.—M. Sirsi (*Journal of the Indian Medical Association*, vol. 32, March 16, 1959) stated that the strain of the organism, the host species, and the physiological state of the host at the time of vaccination influenced the development of immunity. Thus certain physiological and nutritional disturbances have been shown to favor multiplication of BCG and cause progressive lesions leading to the death of the animal. Nutrition plays a prominent but varying role in the development of susceptibility or resistance to infection in various diseases, influencing both multiplication of the organism and antibody production. Nutritional deficiencies are common in school children who are given BCG vaccination in the mass campaign. The development of hypersensitivity to tuberculin is taken as an index of the resistance to tuberculosis conferred by BCG. The tuberculin reaction can be modified by various environmental factors, including vitamin deficiency.

The author studied the results of deficient nutrition on the immunological response to BCG vaccination by challenging immunized animals with virulent tubercle bacilli and noting the effect on the course of the disease. Albino mice known to be susceptible to tuberculosis were used. After a preconditioning period, when the animals were kept on a diet supplying only 30% of their nutritional requirements, they were immunized with 0.1 mg. of BCG vaccine given intraperitoneally. One month was allowed for the development of immunity, after which a virulent human strain of Mycobacterium tuberculosis was injected intravenously. For comparison various control groups of animals, immunized and nonimmunized and on both adequate and insufficient diets, were studied simultaneously. The degree of development of resistance to tuberculosis was assessed from the survival period and weight loss noticed in these animals. It was concluded that vaccination with BCG alone had no adverse effect on the growth of the mice in both the well-fed and underfed groups, while the degree of protection offered by BCG vaccination in the underfed group was in no way inferior to that seen in well-fed group.

Experimental Hydrocephalus.—Nigam and Singhai (*Indian Journal of Surgery,* vol. 21, February, 1959) injected intrathecally (1) 40 and 50% suspensions of India ink, (2) a 20% suspension of kaolin, and (3) a 12-weeks' culture of a bovine strain of Mycobacterium tuberculosis to produce hydrocephalus in dogs and white rats. Some animals died immediately after the injection. The brain, meninges, and proximal part of the spinal cord in those that died or were killed were studied for gross and microscopic changes. The Prussian blue test was used in some to demonstrate the site of obstruction to the flow of spinal fluid. India ink was used in 24 adult rats and 5 dogs; 14 rats and 3 dogs received single injections and the rest had repeated injections up to a maximum of three, the interval between injections being three to six weeks.

Three of the rats died immediately. Ten rats and five dogs showed signs of meningeal irritation, looking ill and lethargic and showing apathy toward food two to three weeks after injection. All the rats had fever, head retraction, deviation of the eyeballs, and loss of weight. One dog developed quadriplegia and another signs of cranial enlargement. The dye was found distributed in the subarachnoid space mainly in the meninges, the maximum deposition being in the basal cisternae and along the vessels in the sulci of the cerebral and cerebellar hemispheres. The duras were devoid of ink except at the site of injection. The pia-arachnoids were studded with ink. The dilated ventricles of the rats, in contrast to those of the dogs, contained ink. The meninges were thickened and adherent at the site of injections in half of the specimens from rats and all from dogs. The brain proper was completely devoid of ink. Half of the rats showed dilatation of the cerebral ventricles. Three of the four dogs showed symmetrical dilatation of the ventricles. In both the anterior horns of the lateral ventricles were most affected. The third and fourth ventricles and cerebral aqueduct were also dilated. The intraventricular foramens were widely patent. One specimen showed only unilateral dilatation of the lateral ventricle. The cerebral cortex was atrophic. Microscopically India ink was seen in the lining cells of the arachnoid with leukocytic infiltration and with perivascular deposition of ink along the Virchow-Robin spaces. Hydrocephalic specimens showed atrophy of periventricular structures, especially the basal ganglions and corpus callosum, with edema of the nerve cells. There was ependymal flattening but the choroid plexus was not involved.

M. tuberculosis was injected into 18 rats, half without prior sensitization and half first sensitized by a subcutaneous injection of the dead bacilli followed by intrathecal injection of living bacilli three weeks later. There were no immediate deaths. All had repeated injections at intervals of four to eight weeks, up to a maximum of three. Only two of the unsensitized and one of the sensitized animals showed definite hydrocephalus. About 40% showed evidence of meningeal irritation, which was not so marked as with India ink. No bacilli were detected in the smears prepared from exudates at the site of injection. Kaolin suspension was injected into 13 rats. Seven died immediately. Of the six surviving animals two showed meningeal irritation and hydrocephalic changes. Others showed no pathological change. Of the three agents used India ink was thus most suitable, the immediate mortality being only 13% and meningeal irritation and dilatation of ventricles being seen in 50%.

The dogs showed a higher incidence of hydrocephalus than the rats with the same agent. The most frequent site of dilatation was the anterior horn. Dilatation was not related to the time elapsing after the first injection or the number of injections. The hydrocephalus was found to be of a communicating variety as evidenced by the Prussian blue test. Two specimens showed arachnoid cysts, probably a result of chronic meningeal irritation.

Protein Content of Breast Milk.—Mukherji and Anwikar (*Indian Journal of Paediatrics,* vol. 26, January, 1959) stated that malnutrition is the greatest single problem in the care of children. Of 12,935 children seen during a period of 11 months in an outpatient clinic 1,589 or 13.6% suffered from gross nutritional deficiency. Of the latter 7% showed evidence of protein deficiency, either in the form of nutritional edema or frank kwashiorkor. Of all the hospital admissions in the same period 5% showed nutritional edema or kwashiorkor. More than 33% of the children attending the hospitals for some other complaints suffered from varying degrees of deficiency of essential food factors. Many cases of nutritional edema were found in children who were breast fed for a prolonged period. Although most cases of kwashiorkor occurred when the child was being weaned, some were seen in children who were still breast fed, mostly after 9 to 12 months. This may have been because the quantity of the milk received by the baby was insufficient or because the protein content of the breast milk of these mothers was significantly lower than normal.

The mothers studied came from poor and malnourished families. Their protein intake was low during both pregnancy and lactation, all of them having had no milk and little animal protein in their diets. They were all overworked and anemic and had had a large number of pregnancies at short intervals. Miscarriages and/or early death of the child occurring soon after birth and due to malnutrition or infection was frequent. Twenty such mothers whose children were admitted with nutritional edema or kwashiorkor and who were still nursing their babies had their breast milk analyzed for protein. Thirty-six lactating mothers served as controls. The duration of lactation in the protein-deficient group was nine months to three years and in the control group it was two months to five years. The results were classified according to the age of the child and age, diet, and parity of the mother.

The micro-Kjeldahl method was used to estimate the total nitrogen content of the sample of breast milk, and the protein content was calculated from this figure. The plasma protein levels were estimated in 10 of these children. In the control group the mean level of protein in the breast milk was 1.34 Gm.% while in the 20 mothers whose children showed signs of protein deficiency the mean protein content of the breast milk was 1.13 Gm.%. Both the upper and lower limits of the protein content of breast milk of control group were slightly higher than those of the group under study. The difference was, however, not marked, the malnourished group showing only a slight diminution in protein content. There was no relation between the parity or age of the mother and the protein content of the breast milk. The plasma protein levels in the children were uniformly low, ranging between 2.8 and 5.3 Gm.%.

Syphilitic Survey.—Nagesh and Kutty (*Indian Journal of Dermatology and Venereology*, vol. 25, Jan.-March, 1959) analyzed the results of 2,000 Venereal Disease Research Laboratory (VDRL) and Kahn tests. Serums that showed strong positive reactions to both tests were regarded as truly positive, while those showing a positive reaction to the VDRL and a negative reaction to the Kahn test were regarded as false-positive, requiring further observation. Often they indicated an early stage of syphilis. Of the 2,000 specimens 310 reactions turned out to be truly positive and 232 were false-positives. Twenty-five of the specimens were spinal fluid and the results with these were uniformly negative. A specimen showing a negative VDRL reaction to the test was not subjected to a Kahn test, since the former is the more sensitive test. Although the VDRL test is sensitive it is not highly specific for syphilis, and a positive result of the VDRL test was taken as a pointer to be confirmed later for the probable existence of syphilitic infection. It is, however, a good test for screening out all definitely negative syphilitic serums.

Hydrocortisone and Osteoarthritis.—Tiwari and Bhargava (*Indian Journal of Surgery*, vol. 21, February, 1959) treated 80 patients who had osteoarthritis with intra-articular injections of hydrocortisone. In most patients the usual methods such as massage, radiant heat, compound mercurial ointment, and therapy with salicylates had been tried with no significant relief. Of 16 patients with knee involvement who received deep x-ray therapy 13 obtained relief. The position of the needle inside the joint was confirmed before injection by aspirating a drop of synovial fluid. After injection the joint was moved through its full range and a firm bandage applied for 24 hours. The amount of hydrocortisone used for each joint was determined arbitrarily. The amount used for single injection was 50.0 mg. for the hip, 25.0 mg. for the knee and shoulder, 12.5 mg. for the wrist and ankle, and 5.0 mg. for interphalangeal joints. The injections were repeated after the return of symptoms or after 48 hours, if no relief followed the first injection.

As a rule relief was experienced 24 hours after injection, pain and a slight effusion developing in the first few hours. No relief was expected if it did not appear within 48 hours. The period of relief varied from one week to more than a year and was three to six weeks in most patients. Early recurrence was observed if the limbs were abused or used excessively. An optimum quantity of the drug was required to produce relief in each joint, but an increase beyond this amount did not influence the duration or amount of the relief. There was no relationship between the severity of the radiologic findings and the extent of relief produced by injection.

After 3 months 32 patients, after 6 months 18, and after 12 months 3 showed no radiologic improvement, while in 2 the condition was aggravated although the joint was free of symptoms. In most, however, the process seemed to have been arrested as shown by repeated roentgenograms. Of the 13 patients with involvement of the knee joint who responded to deep x-ray therapy 12 obtained good results with intra-articular hydrocortisone and one fair results. Of the three who did not respond to deep x-ray therapy one obtained a good result with hydrocortisone and two failed to respond. Thus the results obtained with these two types of treatment are probably similar. Complications included increase in pain 8 to 10 hours after the injection in 52 patients accompanied by warmth and local tenderness in 34 and slight effusion in 9. In patients who responded to the therapy this pain subsided within 24 hours. There was no relationship between the severity of this pain and the possible success of the treatment. Successive injections usually caused less pain. Sepsis did not occur in any of the patients and there were no side-effects of the drug. The results were gratifying in most of the patients treated.

ISRAEL

Tuberculosis.—S. Btesh of the Ministry of Health (*Israel M. J.* 17:241, 1958) stated that mass immigration to Israel after 1948 was associated with an increased incidence of tuberculosis. This disease was not prevalent in the settled Palestinian Jewish population during the period of the British Mandate (1918-1948). This was in part due to the high ratio of young people among the settlers, the relatively high standard of living and housing, and the satisfactory level of medical care. The tuberculosis death rate which in 1948 was 18 dropped to 5.1 per 100,000 population in 1957. Between July, 1948, and the end of 1951 687,000 immigrants entered Israel under a policy of free and unselected immigration. The Yemenite and Iraqi Jewish communities were transported to Israel in toto. Nearly half of these new arrivals were examined. In 288,000 persons examined over 4,000 patients with active tuberculosis were found to have entered Israel during this period. The new arrivals had a prevalence ratio of about 0.6%, as against 0.1% for the settled population in 1947, but the prevalence of tuberculosis among immigrants showed a steady decline from its peak of 0.92% in 1948 to 0.25% in 1951. The highest incidence (0.93%) was found in the immigrants from Turkey and the lowest (0.08%) in the Yemenites.

More significant, perhaps, than the difference in prevalence ratios was the type of tuberculous lesion found. Among 2,090 patients of European origin 0.6% had primary infections, 22% minimal lesions, 68% moderately advanced lesions, and 9.4% advanced lesions. Among 1,648 patients of Asian and African origin, the respective percentages were 5.8, 28.2, 56, and 10. In addition to these differences in prevalence and type the further course of the disease was modified by a number of important factors. These included the degree of resistance of each group to the disease, the unsatisfactory food supply in the country from 1948 to 1953, poor housing and sanitary facilities, the mass case-finding and BCG inoculation campaigns after November, 1948, the routine hospitalization of patients with active infection, and the introduction of modern chemotherapy and surgical treatment.

Due to mass immigration the incidence of tuberculosis among the Jewish population rose rapidly from 5.1 per 10,000 in 1947 to 21.3 per 10,000 in 1950. Many of the immigrants from eastern Europe had been in concentration camps, and about 40,000 arriving in 1948 had also been interned on Cyprus after attempts at "illegal" entry into Palestine. This group exhibited a high morbidity and mortality from tuberculosis in the years after immigration and showed a high incidence of tuberculin reactors. Although most of the pre-1948 Jewish settlers also came from eastern Europe they were a selected group who had immigrated under more favorable conditions between the two world wars. Their morbidity and mortality from tuberculosis were lower than those of the later immigrants from the same countries, and lower than the average for the whole Jewish population. The incidence among them of positive tuberculin reactors was also much lower than among the immigrants. European Jews are known to have a high tuberculosis infection rate, with relatively high resistance and low death rates. The adverse environmental factors of the war years in Europe produced an increased death rate from tuberculosis in this group. The high morbidity and mortality found among eastern European Jewish immigrants were due to the initial high infectivity plus a lower resistance resulting from the stresses of World War II and the period immediately preceding their immigration to Israel.

Immigrants from Yemen coming in 1949 and 1950 had low prevalence rates (0.08%) but in the following years they proved to be extremely susceptible to tuberculosis, and their morbidity and mortality rose rapidly. In 1952 the morbidity was 19 per 10,000, and the mortality 44.4 per 100,000, but by 1957 these figures had dropped to 14.6 and 19.1. The established Yemenite population of Israel comprised about 16,500 Jews, who had immigrated in small groups between 1918 and 1948. Their tuberculosis morbidity after 1952 was similar to that of the newer immigrants, with neither the infection rate nor the susceptibility differing significantly in the two groups.

The Jewish communities of North Africa are scattered over Libya, Tunisia, Algeria, and Morocco. The North African immigration between 1948 and 1950 consisted of about 100,000 unselected persons coming mainly from Tunisia and Morocco. The prevalence of active tuberculosis among this group was not high (0.23%). In 1954 the prevalence of tuberculosis in the Jewish ghettos of Morocco and Tunisia was about 0.17% and it was much lower among the Jews from the Atlas Mountains region. The low infection rate among this group is further indicated by the relatively low incidence of the disease in the first few years after immigration, although it rose steadily to a peak in 1954 (13.2 per 10,000 morbidity, 13.5 per 100,000 mortality). The Asian group included 120,000 immigrants from Iraq, 30,000 from Iran, and a few from Syria, Lebanon, Afghanistan, and Kurdistan. The prevalence of tuberculosis was similar in all groups, about 0.2%, as was the progress of the disease in this population after immigration.

On the whole, the Jewish communities of the Arab countries and Iran (Yemen excepted) did not live in isolation nor were they segregated in ghettos. Many immigrated to Israel in 1950 and 1951, the Iraqi community being transplanted in toto while the immigration from Iran was free and voluntary. Prior to 1948 there was a large established community in Palestine originating from the Arab countries and Iran. The morbidity and mortality studies of this settled group showed no significant difference from those of the new immigrants from the same countries. Both groups had a fairly high resistance to tuberculosis: 0.2% morbidity and 5 per 100,000 mortality, in 1957. In 1935 the prevalence of tuberculosis among Palestinian Jews was 0.39% and 0.38% for urban and rural Jews respectively. Corresponding figures for the Arab population were 0.66% and 0.53%. The most striking finding was the high morbidity rate of the Bedouin nomadic tribes living in the southern desert of Israel. Their contact with other segments of the population had always been minimal, but in the past few years these tribes have tended to restrict their wanderings and have increased their trade relations with the settled population. Their low resistance to tuberculosis is shown by the high morbidity and by the acute form which the disease frequently takes. The morbidity in Bedouins was 0.27% in 1955.

JAPAN

Breast Cancer.—At the 15th quadrennial Medical Congress in Tokyo in April it was reported that the incidence of death from breast cancer in Japan is less than 16% of that in United States. The rate is increasing, however. Dr. Hirayama made a study which led him to conclude that (1) the incidence of breast cancer was highest in women in the menopause and in the upper economic level, (2) with mothers who were pregnant only once or twice the incidence of breast cancer was about three times as great as in those who had had a greater number of pregnancies; (3) the incidence in those who married after reaching the age of 25 years was twice that of those who married earlier, (4) the incidence in those who had had mastitis was twice that in those who had not, and (5) the incidence in women who smoked was significantly higher than that in nonsmokers and in those who ate meat than that in vegetarians. Among the victims of breast cancer the incidence was far greater in those who stopped breast feeding early. In the rural areas the mothers nurse their babies for a year or longer while in the city they switch to bottle feeding much earlier. Among unmarried women, for whom the question of breast feeding does not arise, the incidence of breast cancer is low compared to that of unmarried women in the United States.

Thermal Anesthesia.—At the same meeting Drs. Muto and Watanabe described a new type of anesthesia. Whereas heretofore the low limit of temperature for thermal anesthesia had been considered to be 30 C (86 F), the authors reduced the body temperature of dogs to 10 C (50 F) for three hours, and to 15 C (58 F) for two hours. The circulation entirely ceased, giving an effect similar to that achieved by the mechanical heart. In human subjects the temperature was lowered to 25 C (77 F) with use of ice packs and cold air. This method of anesthesia was used in a series of 168 patients ranging in age from 2 days to 76 years. To hasten recovery massage, electric shock, and stimulants were used. The other advantages of thermal anesthesia were the simplicity and safety of technique, minimal loss of blood, and rapid recovery.

NORWAY

Paranoid Incidents, Delirium, and Amphetamine.—F. Askevold (*Acta psychiat. et neurol. scandinav.* 34:145-164, 1959) reported a series of 14 patients who were admitted to Ullevaal Hospital because of amphetamine addiction. Of these patients seven either were hospitalized with an acute paranoid psychosis or had undergone one or more such psychotic episodes prior to admission. These episodes were transitory and disappeared in a few days. None of the patients suffered from a prolonged schizoid attack. In the other seven, all of whom had abused other drugs, no psychotic symptoms were apparent; but they showed sleeplessness, irritability, or suspicion related directly to the use of amphetamine. The reactions might be interpreted as a continuum in which the individual disposition, the amount of amphetamine taken, and the admixture of other substances were the factors deciding the nature of the reaction. The psychotic reactions were regarded as toxic psychoses, and it was suggested that they were connected with the effect of amphetamine on the mechanism of cerebral oxidation. Four patients developed delirium during the withdrawal of the drug. In these patients a common symptom complex was evident, different from that seen in the delirium associated with alcoholism, morphinism, and barbiturism. The characteristic difference was the lack of anxiety and the only slight vegetative symptoms, while activity and restlessness were greatly increased. There was also a lengthy latent period and the delirium lasted longer.

SWEDEN

Cytological Testing for Cancer of the Uterus.—Early in 1956 Dr. A. Pelzer organized a cytological laboratory at the gynecologic hospital of Malmö. By the end of September, 1957, he had personally examined cell smears from 2,000 women about whom he reported in *Svenska läkartidningen,* March 26. Many of them had uterine bleeding but some had no symptoms. The smears were usually taken from both the fornix and the os uteri and were stained according to the Papanicolaou method. In 1,623 cases two smears were examined. The smears were classified as positive, doubtful, or negative in terms of malignancy. Attached to the positive reports was an attempt to define the histological type of cancer cell identified. No such tentative diagnosis was ventured when cells were scarce or staining was imperfect. Whenever the verdict was "positive" or "doubtful" an exploratory excision or curettage was undertaken, no treatment being given without such preliminary tests. Among the 69 women found to have cancer of the uterus the cytological test was reported as negative in only 5. In 12 the tests resulted in an early diagnosis of malignancy. The author hopes that with improved technique in taking and treating smears, as well as with more experience in their interpretation, these findings can be improved on.

Hospital Beds for Mental Disease.—The latest report (*Svenska läkartidningen*, April 17, 1959) of the Government commission appointed in 1955 to investigate the care of the mentally ill is concerned only with adults, and it shows how time and again the authorities have failed to supply the necessary number of beds. At the turn of the century it was calculated that 3.4 per 1,000 of the population required hospital beds for mental disease. This meant about 10,000 beds; but the 12 mental hospitals then available had only about 7,000 beds in all. In 1945 when 25,000 beds were needed only 18,000 were available. An official report in 1950 sounded a more hopeful note for, although about 3,000 more beds were needed than were available, it was hoped that the gap between need and supply could largely be closed by speeding up the turnover. In 1954, however, the gap between the two was about 5,000 beds. The problem of closing this gap is complicated by the upward shift in elderly persons in the community and by changes in the relative numbers of certain mental diseases, with schizophrenia and manic-depressive psychosis less frequent and reactive psychoses, alcoholism, and the psychopathies more frequent. The psychoses of old age have also become relatively more frequent. Meanwhile about 40% of the appointments of medical officers in Sweden's mental hospitals are vacant for want of applicants.

Lung Cancer and Smoking in Twins.—The dogma that smoking causes lung cancer has been challenged on the ground that persons of a certain temperament may be more likely to smoke tobacco than persons of a different temperament, irrespective of extraneous factors. A hereditary factor, hitherto inadequately explored, and the development of lung cancer in persons who happen to smoke has been postulated. Following this line of thought Prof. L. Friberg and co-workers in Stockholm made a study of twins. They believe that a common factor may predispose to disease as well as to excessive smoking. If, they argue, it is found that identical twins are more alike in smoking habits than nonidentical twins, then constitutional factors may significantly influence these habits. A series of 59 monozygotic and 59 dizygotic pairs of twins were interviewed or sent a carefully worded questionnaire. The degree of concordance of smoking habits within the monozygotic and the dizygotic pairs was investigated (*British Medical Journal*, April 25, 1959) and shown to be significantly greater within the monozygotic pairs.

UNITED KINGDOM

Ulcerative Colitis and Cancer of the Colon.—Rosenqvist and co-workers (*Lancet* 1:906, 1959) studied a series of 500 patients with ulcerative colitis and concluded that one such patient in three develops carcinoma if the disease is present for 10 to 20 years. Since carcinoma of the colon is highly malignant and often difficult to diagnose, colectomy is indicated as a prophylactic measure. Much has been written about the psychosomatic origin of ulcerative colitis and the use of psychotherapy in its treatment. Rosenqvist pointed out that by the time these patients are hospitalized the condition may already be precancerous or even malignant and that psychotherapy and the removal of possible stress factors are no longer important. Relative freedom from the symptoms of ulcerative colitis does not insure that cancer will not develop. On the contrary 26 of the patients were completely or almost free of symptoms for several years before the lesions became malignant. One of the patients had been free of symptoms for 12 years.

Minister Accused of Delay.—Mr. Walker-Smith, Minister of Health, was severely criticized by the House of Commons Select Committee on Estimates for delaying an inquiry into the possible misuse of the domiciliary consultation service, a delay that is contrary to the public interest. The service provides for a specialist to go to the home of a patient when requested by a family physician. The issue arose in the autumn of 1957 after expert evidence that the number of house calls seemed inordinately high. It was claimed that family doctors frequently failed to attend with the consultant. There had been a rise in the number of house calls made by full-time specialists since they became entitled to payment in 1955. The report called attention to the fact that it was originally stated that Mr. Walker-Smith was taking steps to institute inquiries, but that he had gotten no further than to consider the form of an inquiry.

Mr. Walker-Smith stated that, since the need for a domiciliary consultation is essentially a question of clinical judgment in individual circumstances at a particular time, it is difficult to devise methods of ascertaining whether misuse of the service exists. The committee recommended that if the previous evidence was not contradicted by information now sought, the inquiry should be made without further delay.

Hospital Equipment Exhibition.—A reconstruction of the laboratory at St. Mary's Hospital where Sir Alexander Fleming discovered penicillin was shown at the second International Hospital Equipment and Medical Services Exhibition in London, in May.

Most of the material for this exhibit was collected by Lady Fleming, who continues to work in the laboratory. It is intended for a permanent museum which will later be housed in the Wright-Fleming Institute at St. Mary's. The exhibit included an authentic reproduction of the dish in which Sir Alexander first observed the lifesaving mold, Sir Alexander's microscope, and many manuscripts and awards never before seen by the public. Alongside the reconstructed laboratory there were examples of the latest equipment for producing penicillin.

The development of surgery and its debt to science and engineering was illustrated by examples of modern surgical equipment and of instruments used in hospitals of the 17th and 18th centuries. Old prints of hospital scenes from the 16th to 18th centuries were lent by hospitals and museums. A section devoted to electromedical equipment showed how defects in or damage to the blood stream, brain, and heart can be accurately diagnosed before operation. A model of a 2,000,000-volt machine used in the treatment of cancer and now in use in several British hospitals was flown from Canada. An iron lung and apparatus which can replace vital organs, such as the lungs and heart, during operations were also shown.

District Nurses.—Few towns and villages are without a district nurse. Patients who need treatment at home, including a large proportion of the old and the bedridden, are completely dependent on her. The service of which she is a member celebrates its centenary this year. It will therefore surprise many people to find that the Queen's Institute of District Nursing is finding it necessary to launch an appeal for $700,000. The reason is that district nursing has not been wholly integrated into the National Health Service (NHS). Its running costs are charged to the state, but the training of nurses is not. Local health authorities contribute to a certain extent, but most of the expenses of training must still be found by voluntary contribution. More than 700 nurses are trained every year and the costs have risen steeply. The question arises whether the district nurses should be taken over entirely by the NHS. Some believe it is a salutary thing that the welfare state should still leave room for voluntary contributions and private charity.

Radiation Hazards in Hospital.—A committee was appointed by the government in 1956 to study the dangers of the diagnostic and therapeutic uses of radiology, inspired by a Medical Research Council report on the hazards to man of nuclear and allied radiations. The committee, consisting of one or more physiologists, radiologists, gynecologists, and authorities on the medical use of radioactive isotopes, has made its report (Radiological Hazards to Patients, Her Majesty's Stationery Office, 1959). It considers that mass radiography, if properly conducted, is safe, and that the benefits far outweigh the slight risk. Nearly 5,000,000 persons have chest films taken by mass radiography each year. These examinations bring to light 18,000 cases of tuberculosis and 63,000 other abnormal conditions of the chest annually, including 2,362 cases of cancer of the lung and 12,000 cases of heart disease. Thus every year 80,000 cases of crippling or fatal disease are discovered in the early stages before the patient has symptoms. According to the committee the indefinite continuation of mass radiography at its present rate would not add more than 20 cases of leukemia to the annual incidence of 2,500 cases and might produce none at all. In any case this is a small price to pay for the benefits received. The committee stressed the possibility that patients might refuse the benefit of diagnostic and therapeutic radiology because of widespread misleading publicity on the hazards of irradiation.

The committee laid down certain safeguards. The dose of radiation should be the minimum consistent with the taking of a good film. Scatter and extraneous radiation should be reduced as far as possible, and mass radiography should not be used in children or pregnant women. In making its report the committee surveyed the numbers and types of radiographic examinations being made, the number of films used, and the apparatus available in hospitals and clinics. Measurements were made of the dose of radiation received by patients undergoing different types of radiographic examination.

New Radioactive Hazard.—New radioactive hazards to industrial workers are the "go-devils" used by oil, gas, water, and other industries for detecting whether newly laid mains are free from obstruction and for the routine maintenance of existing pipelines. Go-devils are tightly fitted rubber washers, scraper vanes, or wire brushes mounted on a central core. They are pushed through pipelines by means of water or compressed air, and they sometimes get jammed against an obstruction. Determination of their exact location can be time-consuming and costly, involving excavations over a long length of pipeline if this runs underground. The inclusion of a radioactive tracer in the central core, which is exposed on contact with an obstruction, overcomes the difficulty of detecting the position of the go-devil. Then it can be detected above ground by a Geiger counter. The handling of this radioactive material has become another industrial hazard, and a code of practice was recently laid down to prevent unnecessary exposure of personnel.

Physicians and the Press.—At the Royal Society of Health congress in Harrogate the anonymity of the medical profession was criticized in a discussion of the relationship between doctors and the press. Dr. W. S. Parker said that one of the most difficult problems to be overcome was the reticence of physicians in discussing professional matters and in making any comment on topics of medical interest. More contact should be made between the medical profession and the public through the press, which at present is a neglected route. While the reticence of individuals should be maintained, contact with the public could be made intelligently and in language that could be understood. He advocated a grant from the National Health Service budget toward health education. As little as 1%, invested in such a program, would pay handsome dividends. These views were supported by Dr. Harvey Flack who urged that physicians who are governed by outmoded ethical rules cast aside their inhibitions and give journalists positive, forthright statements that could be quoted. There is a need for doctors who can express themselves accurately and responsibly to the ordinary layman. The editor of the *News Chronicle* said that it was the doctors' duty to keep the public informed. They tended to devalue their role in keeping the community healthy. The medical profession and the press must come to terms on the best methods of informing the public about preventive medicine. Even with poliomyelitis the public had not been given a clear impression of the facts or it would have cooperated better in the vaccination campaign.

The medical correspondent of the *Observer* said that before the press could educate society it must enlist the help of the medical profession. Some physicians laid the blame on the press. Dr. J. Burn attacked the press for unhealthy publicity on legalized abortion, artificial insemination, and other matters, but he believed the press could play a great part in health education. Other speakers blamed the press for distorting statements made to them by doctors. Some of the delegates stated that it was not the function of the press to educate its readers. In their opinion health education was better done through the schools and colleges and directly by the physician.

Poisoning from Marking Ink.—An outbreak of methemoglobinemic cyanosis in six newborn babies due to the absorption of aniline dye from their diapers was reported by Ramsay and Harvey (*Lancet* 1:910, 1959). The first case occurred in an infant who became cyanotic on the 8th day of life and passed numerous loose green stools. Routine blood studies showed no abnormality but in view of the extreme cyanosis the blood was examined spectroscopically and intense absorption bands of methemoglobin were observed. Ascorbic acid (200 mg.) and methylene blue (5 mg.) were injected intravenously and within 15 minutes the infant's skin became a normal pink color. The cause of the cyanosis was not suspected until five other babies in the same hospital were found to be similarly infected. Inquiry revealed that new diapers were normally marked with colored cotton thread but owing to a defect in the sewing machine they were marked on this occasion with an indelible ink made from an aniline dye. All the affected babies were given new diapers marked with this dye. Aniline dyes in marking ink are known to be absorbed percutaneously and to cause methemoglobinemia. Once the cause was recognized and the source of poisoning removed the babies recovered without any specific treatment.

Obstetric "Oil, Bath, and Enema."—The administration of castor oil, followed by a soap enema and a hot bath, is one of the oldest and most frequently attempted methods of inducing labor. Because of its unpleasant features many obstetricians have abandoned the use of castor oil. Mathie and Dawson have assessed, with the aid of a tocograph, the possible effects of this procedure on uterine contractility in late pregnancy (*Brit. M. J.* 1:1162, 1959). Sixty women who were between 38 and 41 weeks pregnant were divided into four groups, excluding those who appeared likely to have an abnormal labor and those showing any sign of the onset of labor. The first group had a complete OBE (castor oil, hot bath and enema); only castor oil was given to those in the second; only the enema to those in the third; and only a hot bath to those in the fourth group. The changes in uterine activity in each patient were assessed by the guard-ring tocodynamometer. This instrument is claimed to provide an absolute measurement of the changes in intra-amniotic pressure and thus of uterine contractions. The head of the instrument was applied to the anterior abdominal wall over a fluid-filled part of the uterus and held in place with a stiff elastic belt passed around the abdomen. From a study of the tocographic tracings the amplitude in grams per square centimeter and the duration and frequency of each contraction were calculated.

The tracings showed that a complete OBE produces a marked increase of uterine activity, increasing the contractile work done by the uterus by an average of 264%. The administration of castor oil alone increased the contractile work by an average of 186%, and a soap enema alone increased it by 95%. A hot bath alone had no significant effect. In the control group studied there was a spontaneous variation of uterine activity in the course of three hours with a mean of –4%. The authors therefore concluded that the marked increase in uterine activity produced by an OBE justifies its retention in obstetrics. Only the castor oil and enema played a significant part, but the hot bath had other advantages.

CORRESPONDENCE

MUSCLE WORK AND BODY TEMPERATURE

To the Editor:—A few years ago an article, by Karpovich, on the subject of warming-up exercises appeared in The Journal (Nov. 17, 1956, pp. 1117-1119). The author recently referred to it in an international publication. The subject is of immense interest to athletes throughout the world and to all those engaged in research in this sphere. Since Karpovich's writings, as well as reports in the *Research Quarterly*, indicate that certain facts connected with the problem may not be generally known, knowledge of procedures in previous research is of value in further study in this field.

About 50 years ago Prof. J. Lindhard, founder of the Copenhagen University Gymnastic Theoretical Laboratory, found that an athlete had a rectal temperature of 40.5 C (104.9 F) immediately after completing a run (*Gymnastikteori* 2:135, 3:288, 1918). Since the "normal" body temperature is 37 C (98.6 F), what was the cause of this unexpected high temperature?

This subject was investigated by Dr. Marius Nielsen (*Skandinav. Arch. f. Physiol.* 79:193-230, 1938), whose study was made on men who worked in the nude. As these men worked, their body temperatures (inside the trunk) and skin temperatures were measured by thermoelectric means. The work, measured on a Krogh stationary cycle ergometer, with rates varying from 360 to 1,440 kg.-m. per minute (in one case for a duration of 4½ hours), was carried out at the Copenhagen University Zo-ophysiological Laboratory. The room temperature was varied from 5 to 36 C, which affects the body's heat regulation by convection and radiation; the humidity of the air was increased from 50 to 80%, affecting the heat regulation by evaporation; and there were fans to move the air, affecting the heat regulation by convection.

It was found that the body temperature rises to a definite and constant level, the height of which is determined by the intensity of work. The body temperature, within a wide range, was unaffected by the room temperature, unaffected by the humidity of the air, and also unaffected by moving the air by fans. The rise of the body temperature was practically proportional to the oxygen intake. At rest the body temperature was about 37.0 C (98.6 F); at work rates of 360, 720, 1,080, and 1,260 kg.-m. per minute, the body temperature rose to 37.4 C (99.3 F), 37.8 C (100.0 F), 38.2 C (100.8 F), and 39.0 C (102.2 F), respectively.

Therefore, when we say that the normal body temperature is 37 C, we must add "when the body is at rest." It is just as normal to have a body temperature of 39 C during a work rate of 1,260 kg.-m. per minute for some time. Another fact is that it takes 30 to 50 minutes to raise the body temperature, depending on the work rate. From these facts we may conclude that the center for the regulation of the body temperature is not failing to function accurately during intensive muscle work; on the contrary, the body temperature seems to maintain its level more exactly during muscle work than at rest.

Another question arises: What is the organic "reason" for high temperature during muscle work? Pavlov once said that nervous centers act and react in a most intelligent way in relation to stimuli from the surroundings. It is worthy to note that athletes know from experience that it is unpleasant to perform, and especially to compete, in an event if they feel cold, and so they instinctively jump and swing their arms or do other vigorous exercises before the athletic event. Ballet dancers also work vigorously before going on stage.

Dr. Marius Nielsen points out that chemical processes accelerate in higher temperature. It is also known to athletes and ballet dancers that it is more pleasant to perform when the body is warm than when it is cold. This brings us to the articles by Karpovich (*FIEP*, bull. 2, 1958; *Springfield Coll. Bull.* [Feb.] 1957) in which he fails to find advantages in preliminary warming-up exercises.

Asmussen and Bøje's study (Asmussen: *Tidsskr. f. Legensøv.* no. 3, 1939; Asmussen and Bøje: *ibid.*, no. 2, 1945; *Acta Physiol. Scandinav.* 10:1, 1945) indicates that high body temperature as a result of warming-up exercises is advantageous and that the more vigorous the warming-up exercises the better the athletic results (of certain types). This, of course, demands that the athlete be in a good condition and able to stand prolonged and vigorous warming-up exercises as well as the following event, and he must do his warming-up exercises and perform in the event without any pause for rest.

It might seem strange that Hale and Karpovich fail to find warming-up effective while Asmussen and Bøje found distinct improvement as a result of warming-up exercises. The reason for such conflicting results probably is to be found in their different methods of study. The fact that a runner broke a record without warming-up, as Karpovich points out, can hardly be accepted as convincing proof. Records were broken in years past when the problem of warming-up was unknown. Furthermore, records are broken not during training but at sports meetings and presumably partly as a result of the stimulating effect of the excitement, i. e., the additional concentration of epinephrine.

When Asmussen and Bøje, at Copenhagen University, studied the effect of warming-up on physical performance, consisting of a sprint of 35 pedal revolutions on a Krogh stationary cycle ergometer, which in physical output is more or less equal to a running sprint of 100 m., they used the following procedure. All experiments for a period of about five weeks were made in the mornings. The subjects were between 21 and 39 years of age. Some of them were well-trained sportsmen, some were nonsportsmen, and others were professional cyclists. Some were of the leptosome type, and others were of the athletic and pyknic types. Arriving at the laboratory in the mornings, the subjects had a 30-minute resting period of lying down before the experiment began, whether they did warming-up exercises or not. Warming-up exercises consisted of 30 minutes of cycling on a Krogh stationary cycle ergometer and were done at a work rate of about 600 kg.-m. per minute. On alternating days the sprint (35 pedal revolutions) was performed without preliminary warming-up, immediately after the 30-minute resting period.

They found that the times for the sprint in all subjects were better with preliminary warming-up exercises. A typical graph shows that a subject's average time was 13.7 seconds without warming-up but 12.6 seconds with preliminary warming-up, which is an improvement of 1.1 seconds (or 8%).

Asmussen and Bøje made a similar study but on 450 pedal revolutions, which in physical output is about equal to a 1,500-meter run. Here again was found a noticeable effect of preliminary warming-up exercises. A typical graph from this study shows that a subject had an average time of 4 minutes and 39.7 seconds without preliminary warming-up but 4 minutes and 25.2 seconds with preliminary warming-up, which is an improvement of 13.5 seconds (or 5%). There should be no resting period between the warming-up period and the following event. More recent studies show that the effect of warming-up diminishes by an intermediate period of rest, i. e., the longer the period of rest the less effective is the preliminary warming-up. Best results are achieved after a warming-up period of 30 to 50 minutes, but 10 to 15 minutes of warming-up exercises also result in some improvement in the following event. Warming-up exercises should preferably be performed with the muscles which are to be used in the event. The athlete's training condition must be such that he can endure vigorous and prolonged warming-up exercises as well as the event without an intermediate period of rest. Warming-up exercises may not be beneficial to athletes in preparation for activities of very long duration, such as marathon running.

The above reports may be of interest to athletes and, perhaps, to investigators who might use them as bases for further research.

DISCUSSIONS AT BEDSIDE

To the Editor:—As one of a small group of Fellows of the American College of Physicians, I had the privilege last April of attending lectures at El Instituto Nacional de Cardiologia, in Mexico City, and meeting its renowned director, Dr. Ignacio Chavez. I was impressed by this unique, modern center of cardiology, not only by the buildings and the newer devices for detection and treatment of heart ailments but also by the down-to-earth awareness that all this was for the treatment of ordinary human beings who were in distress. Dr. Chavez, whose scientific achievements are equaled by his charm as a host and his dedication to his patients, was justifiably proud when he showed us through this great institution. One of his greatest satisfactions came from a room at the end of each ward in which were only a table, a few chairs, and some reference books. He said:

> This is our talking room. Let me make myself clear by telling you a . . . story. Once, while making rounds in the children's section, I overheard two youngsters . . . not more than six years old. One said: "I've got a rheumatic heart murmur in my mitral valve." The other, not to be outdone, answered: "Oh, that's not so much. I've got a double aortic murmur. It's more serious than yours." It was then that . . . it became hospital policy never to discuss a patient at his bedside. If tots could become "little doctors" just by listening to our bedside discussions, think how much iatrogenic disease we spread when in earshot of grownups. Now we take necessary notes at the bedside, and after rounds we all . . . [go] to our talking room where we can discuss treatment and prognosis without fear of adding unnecessary burdens of anxiety to an already sick patient.

While many American institutions have adopted a similar policy, from personal observation I know that there are still too many doctors who "think out loud," not only at their patient's bedside but also during office management. The art of medicine has lagged behind its sister, science. We must keep reminding ourselves that we treat human beings, not case histories. That's all there is to the art of medicine.

MEDICAL LITERATURE ABSTRACTS

INTERNAL MEDICINE

Augmentation: A Third Stage of Digitalis Therapy. E. H. Blackard and T. R. Harrison. A. M. A. Arch. Int. Med. 103:543-550 (April) 1959 [Chicago].

The authors studied the effects of administering gitalin, a short-acting digitalis preparation, to the point of minor toxic manifestations in 33 patients with congestive heart failure. Of these, 18 had been treated by other physicians according to the accepted method of initial digitalization followed by administration of the standard maintenance dosage with various preparations. All 18 were supposedly optimally digitalized and were referred to the authors because of refractory heart failure. It was found that these patients were actually underdigitalized, and most of them were able to take within a few days one-half to 2 of the usual full digitalization doses before minor toxic symptoms developed. All of them showed subjective improvement, and 11 showed undoubted objective evidence of improved cardiac function. In 7 of the 11 the improvement was apparently due to digitalis alone.

These observations indicated that the current standard methods of administering digitalis are inadequate and that periodic augmentation is desirable in patients who are having symptoms despite receiving the drug in the usual accepted maintenance dose. For such augmentation a short-acting digitalis is to be preferred because of the brief duration of such minor toxic effects as anorexia, nausea, and weakness. For the most desirable results of improved cardiac function, precautions should be observed during periods of augmentation as follows: 1. The patient should take the drug himself and only after meals and provided the appetite shows no sudden decrease. 2. During the period of increased dosage the patient should be seen at least once daily by a physician. 3. Potassium chloride should be administered with each dose of digitalis during the supplementary period. 4. A clear distinction should be made between anorexia and nausea due to digitalis and symptoms resulting either from abdominal congestion (which is usually an indication for more digitalis) or from concurrent disease, such as uremia, or from such drugs as ammonium chloride, morphine, or aminophylline. 5. It should be recalled that premature beats are frequently due to the underlying cardiac disorder as such, and that under such circumstances they may be abolished by digitalis. Rarely, this is true for bigeminal rhythm.

Of the 33 patients to whom gitalin was given to the point of minimal untoward effects, 25 (75%) showed gastrointestinal symptoms without evidence of cardiotoxicity. In only 3 was the reverse observed. No serious toxic effects were seen. It is suggested that periodic augmentation of the dosage of digitalis should be employed, with the previously listed safeguards, in patients who are failing to show satisfactory control of congestive heart failure.

Asian Influenza A in Boston, 1957-1958: I. Observations in Thirty-Two Influenza-Associated Fatal Cases. C. M. Martin, C. M. Kunin, L. S. Gottlieb and others. A. M. A. Arch. Int. Med. 103:515-531 (April) 1959 [Chicago].

The authors report on 14 female and 18 male patients, between the ages of 11 and 71 years, with Asian influenza A who died in the Boston area between August, 1957, and March, 1958. The clinical courses, laboratory findings, and autopsy findings in these patients were similar to those associated with fatal cases during earlier influenza epidemics. Of the 32 patients, 12 had advanced heart disease, and 10 had either chronic intrinsic pulmonary disease or chronic respiratory insufficiency secondary to neurological or neoplastic disease. Four women died during pregnancy. Fifteen patients had influenza without bacterial complication, 11 had postinfluenzal staphylococcic pneumonia, and 6 had postinfluenzal nonstaphylococcic bacterial pneumonia. Influenzal and postinfluenzal pneumonias thus were the commonest and severest complications. Bacterial, and particularly staphylococcic, pneumonia, when it occurs in adults after influenza, is generally severer and more rapidly progressive than it is under other circumstances. The frequent occurrence of hemoptysis, tachypnea, and cyanosis in the patients suggests that these symptoms, with or without prominent pulmonary findings, are highly indicative of potentially fatal disease. The interval between the time when severe disease was first recognized and the time when death occurred was 48 hours or less in 25 patients (81%). In a consider-

The place of publication of the periodicals appears in brackets preceding each abstract.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover 1950 to date only, and no photoduplication services are available. No charge is made to members, but the fee for others is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

able proportion of the patients with severe influenza, the bacteriological, roentgenographic, and other laboratory techniques used were not effective in distinguishing between pure influenza and postinfluenzal bacterial pneumonia rapidly enough to be useful for specific treatment.

Strains of Asian influenza A virus were isolated from antemortem throat washings or postmortem tissues in 14 (44%) of the 32 patients, and, by means of fluorescein-labeled antibody techniques, influenza A viral antigen was shown in interstitial macrophages of respiratory tract tissues in 9 patients (31%). Except when Gram-stain studies of sputum revealed specific pathogens or when roentgenographic studies revealed pulmonary cavitation, it was not possible to make a prompt diagnostic differentiation between pure influenzal pneumonia and postinfluenzal bacterial pneumonia. It is suggested that in times of epidemic influenza, and in areas in which staphylococcic infections are highly prevalent, patients presenting with the signs usually associated with fatal influenza should be treated promptly as having bacterial pneumonias, unless or until that diagnosis is disproved. The need for a practical "artificial lung" to support patients in the acute respiratory insufficiency of severe influenza is emphasized.

Asian Influenza A in Boston, 1957-1958: II. Severe Staphylococcal Pneumonia Complicating Influenza. C. M. Martin, C. M. Kunin, L. S. Gottlieb and M. Finland. A. M. A. Arch. Int. Med. 103:532-542 (April) 1959 [Chicago].

The authors compared the findings, clinical course, and management in 11 patients with Asian influenza A who had fatal postinfluenzal staphylococcic pneumonia, and were reported on in the preceding paper, with those in 9 patients with nonfatal staphylococcic pneumonia following Asian influenza A, who were observed and studied in Boston and environs during the pandemic of that disease in 1957-1958. The fatal cases were generally marked by severer and more rapidly progressing illness, less accurate diagnosis, and relatively ineffective antibiotic therapy. Although most of the 20 cases of staphylococcic pneumonia arose in the community rather than in hospitals, the strains of staphylococci responsible for the occurrence of pneumonia were commonly resistant to multiple antibiotics and were of bacteriophage types most often associated with hospital-acquired infections.

Disk sensitivity tests performed directly on sputum or body fluids containing staphylococci afforded a rapid, relatively accurate guide for the selection of effective antibiotics. Although the antibiotic combination of erythromycin and chloramphenicol, with or without novobiocin, was most often associated with survival of the patients, the number of patients was too small and the treatment schedules too varied to state with certainty the superiority of any one effective regimen over another. It is suggested that during epidemic influenza, in areas in which major staphylococcic infections are common, all patients with the signs of potentially fatal influenza be diagnosed and treated promptly as having staphylococcic pneumonia caused by the prevalent types of antibiotic-resistant staphylococci until the diagnosis can be disproved.

Serum Aldolase in Muscle Disease. R. A. Thompson and P. J. Vignos Jr. A. M. A. Arch. Int. Med. 103:551-564 (April) 1959 [Chicago].

The authors determined the serum aldolase level in a series of patients, children and adults, with neuromuscular diseases manifested primarily by skeletal muscle weakness. The serum concentration of aldolase was elevated in patients with primary myopathy including degenerative and inflammatory muscle disease, such as polymyositis, muscular dystrophy, and dystrophia myotonica. The highest serum aldolase levels were determined in patients with polymyositis and in patients, between the ages of 3 and 15 years, with muscular dystrophy. The level of serum aldolase in patients with muscular dystrophy decreased with increasing age, diminished muscle mass, and reduced functional ability. Serum enyzme levels appear to have prognostic value in patients with muscular dystrophy, since there is a positive correlation between net loss of muscle mass and serum enzyme concentration.

Patients with muscle weakness due to neurogenic atrophy or impairment of conduction at the neuromuscular junction had a normal serum aldolase level. This finding is a helpful differential diagnostic aid in separating these patients from those with primary myopathies. Determinations of serum aldolase level may give valuable assistance in regulating steroid therapy in patients with polymyositis. Biochemical changes in muscle as reflected by a decrease in aldolase serum levels precede clinically demonstrable improvement in muscle strength.

An Assessment of Long-Term Anticoagulant Administration After Cardiac Infarction: Report of the Working Party on Anticoagulant Therapy in Coronary Thrombosis to the Medical Research Council. G. Pickering, W. M. Arnott, R. Biggs and others. Brit. M. J. 1:803-810 (March 28) 1959 [London].

There has been little agreement on the efficacy of anticoagulant therapy in lowering the risk of death or recurrent infarction. The main aim of the clinical trial here reported was to establish whether, in patients who had survived at least one month after their most recent infarction, the continuous administration of an anticoagulant drug (phenindione), in doses sufficient to double the one-stage "prothrombin" time, would appreciably reduce the risk of recurrence and death below the levels concurrently observed in a series of patients with illnesses of comparable severity, given tablets containing only 1 mg. of phenindione. The 383 patients who had recovered from the acute phase of a cardiac infarction of defined severity were classified according to their previous infarct history and allocated at random within each hospital center to these high-dosage and low-dosage series. Both groups of patients were seen at regular intervals every 2 or 3 weeks and were clinically assessed more fully by roentgenologic and electrocardiographic methods every 3 months. Laboratory control was maintained by Quick's test of the one-stage "prothrombin" time, and in the high-dosage series the amount of the drug administered was adjusted to ensure a level 2 or 2½ times the control value. Three indexes of the effectiveness of the regimens were used: (1) death from all causes, from cardiovascular disease in general, and from recurrent myocardial infarction in particular; (2) frequency of myocardial reinfarction of varying degrees of severity; and (3) subsidiary data on return to work and the presence of anginal pain or dyspnea at the time of the last examination. A note was made of all incidents, such as embolism and hemorrhage, which might be affected by the anticoagulant therapy.

Comparisons were made between the outcome in different subgroups of patients and at different stages of the follow-up period which ranged up to a maximum of 3 years. The analysis was as follows: 1. Although the death rate was higher in the low-dosage series, there is just the possibility that the difference could have occurred by chance. No difference was apparent in women, but the numbers were too small to exclude such a difference. 2. When infarcts serious enough to cause permanent withdrawal from the trial were added to deaths as a combined index of prophylactic failure, there was a significant reduction in their frequency among men receiving the high doses; and there was a suggestion of a better result in men under the age of 55 years. 3. The same trends appeared even more clearly when the total reinfarction rate was used as the basis of comparison. Under the age of 55, men on high doses suffered recurrent infarctions at only one-fifth the rate of those on low dosage, and over that age the rate was halved by high dosage. These differences are statistically significant. 4. The proportionate reduction in the risk of reinfarction achieved by the high-dosage regimen was slightly greater among patients with a previous history of one or more infarcts, but the difference is not statistically significant. 5. The difference in the death rate was most evident in the first 6 months of the follow-up period, but the disparity in the reinfarction rate was maintained for at least 2 years of the follow-up period. 6. More men given the higher doses returned to work during the period, and they were more often free from angina. 7. There were 15 withdrawals from the high-dosage series because of the onset of conditions actively or potentially associated with hemorrhage.

Four major cerebrovascular accidents—3 causing withdrawal and 1 death—were reported in the high-dosage series. Only 1 patient on low dosage suffered a cerebral hemorrhage, but embolism was a major complicating feature in the terminal illness of 3 patients. There were 48 minor hemorrhagic incidents in the high-dosage group compared with 8 among those on low dosage. The authors compared these results with those in 2 similar studies and found close agreement in many respects with one of these clinical trials. It appears that phenindione administered continuously in the conditions of this trial can make a useful, if limited, contribution in the after-care of patients who have recovered from the acute phase of myocardial infarction.

Subacute Pulmonary Hypertension Due to Chorionepithelioma. **K. D. Bagshawe and W. D. W. Brooks. Lancet 1:653-658 (March 28) 1959 [London].**

The term "subacute pulmonary hypertension" has been applied to the condition produced by carcinomatous metastases in the lungs. Three forms have been described: (1) carcinomatous lymphangitis in which the lymphatics are extensively invaded by cancer cells causing compression of alveoli and capillaries without invasion of the blood vessels; (2) carcinomatous lymphangitis in which cancer cells from the perivascular lymphatics compress and invade the small arteries and arterioles producing a pulmonary endarteritis which may be followed by intravascular thrombosis; and (3) a pure embolic form in which the pulmonary arteries and arterioles are occluded by cancer-cell emboli and secondary thrombosis.

The purely embolic form seems to be rare. One of the few reported cases of this form was mentioned by McMichael in 1948 in a review of pulmonary heart disease, and the authors describe this case here together with 2 others. The patient reported in 1948 and one of the 2 other patients died. These 2 women presented with dyspnea, cyanosis, pulmonary hypertension, and low cardiac output. They were found at autopsy to have chorionepithelioma confined to the pelvic veins and pulmonary arteries. The third patient has similar clinical features and a high gonadotropin titer and is thought to have a similar pathological process, though neither diagnostic curettage nor careful histological examination of the uterus showed the presence of chorionepithelioma.

The diagnosis is difficult. Only 1 of the 3 cases presented was diagnosed while the patient was still alive, but after considerable delay. In one of the fatal cases thyrotoxicosis was suspected, and pulmonary embolism was suspected as the cause of the chest pain. In the second case a right-to-left intracardiac shunt was considered. While distinction from simple emphysema is not difficult, tuberculosis has been mimicked in some cases. Differentiation from subacute thromboembolism will be difficult, since the basic mechanisms in the 2 conditions are similar. Distinction in the absence of a pelvic tumor will be possible only by means of biological tests for gonadotropic activity. It therefore seems desirable to perform such a test in all cases of thromboembolism in women of menstrual age.

The presentation with subacute pulmonary hypertension of 2 patients with latent chorionepithelioma within a period of 14 months under the care of one physician suggests that the condition may be less rare than the literature indicates. Such cases may have been diagnosed as thromboembolism or as idiopathic pulmonary hypertension. Interest in chorionepithelioma, which is usually rapidly progressive, has been heightened by reports of new methods of treatment. Prolongation of life has probably resulted from the use of nitrogen mustard. Because chorionic tumors are fetal in origin and therefore of different genetic structure from the maternal tissues, it has been suggested to transfer tissue from the husband to the patient with the object of increasing her antigenic response to the tumor cells. The one surviving patient of the 3 presented here showed a good response to treatment with anti-folic-acid and antipurine drugs in high intermittent dosage. This treatment had been suggested by Hertz and others in 1958 and had effected remissions in a number of patients.

Botulism in Arctic Alaska: Report of 13 Cases with 5 Fatalities. E. S. Rabeau. Alaska Med. 1:6-9 (March) 1959 [Anchorage].

Five outbreaks of botulism in Arctic Alaska are reported. At Kotzebue in 1947, 3 persons developed clinically typical botulism, and 2 died; and in 1948 there were 2 cases, with one fatality. In 1950 at Point Hope, 5 cases of nonfatal botulism occurred, and the organism, Clostridium botulinum, type E, was isolated in some of the remaining food. In 1952, near Selawick, one case occurred with death. At Kotzebue in 1956, 2 cases, with one fatality, occurred. In both the last 2 outbreaks, Cl. botulinum, type E, was identified. The same foodstuff, beluga (white whale), uncooked and preserved in seal oil, was responsible for all 5 outbreaks. In 3 outbreaks Cl. botulinum, type E, was isolated, and it seems logical to assume that it was probably the factor in the other 2.

SURGERY

Treatment of Myocardial Infarction with Anticoagulants. B. V. Konyaev. Klin. med. 37:81-90 (March) 1959 (In Russian) [Moscow].

The author reports on 611 patients with myocardial infarction, 221 of whom were treated with anticoagulants and 390 without anticoagulants. Anticoagulants were given to patients with more extensive infarction frequently complicated with myocardial aneurysm and circulatory insufficiency. Mortality in the group treated with anticoagulants amounted to 7.2%; it was 11% in the control group. The incidence of thromboembolic complications was 10.8% in the first group and 13% in the second group. Treatment with anticoagulants was most effective in patients with recurring and extensive myocardial infarction complicated by circulatory insufficiency. However, the anticoagulant therapy does not prevent the development of extensive myocardial necrosis or of recurring infarction, especially in the presence of arteriosclerotic coronary vessels; nor does it prevent further extension of the existing infarction. There was not a more frequent formation of cardiac aneurysms and their rupture in the anticoagulant-treated group, despite the fact that the patients in this group were afflicted with a more severe pathological state.

The anticoagulants should be given at the earliest possible time so as to accomplish the lowering of prothrombin to 40-60% level as early as possible. Sudden termination of the anticoagulant treatment leads to thromboembolic complications, and for that reason it should be terminated gradually. Hemorrhagic complications in the group treated with anticoagulants amounted .to 16.6%. These hemorrhages were chiefly renal and were observed as mild hematuria.

The Coexistence of Primary Lung Cancer and Other Primary Malignant Neoplasms. C. G. Moertel, H. A. Andersen and A. H. Baggenstoss. Dis. Chest 35:343-347 (April) 1959 [Chicago].

Of 1,588 patients in whom a histological diagnosis of cancer of the lung was confirmed at the Mayo Clinic between 1944 and 1953, 65 (4.1%) had one or more other primary malignant neoplasms. Of the 65 patients, 59 were men and 6 were women. In 27 patients the lesions were diagnosed simultaneously; in 8 patients diagnosis of the pulmonary lesion preceded diagnosis of the other neoplasm by periods of 1 to 5 years; and in 30 patients diagnosis of the pulmonary lesion followed that of the other neoplasm by periods of 1 to 29 years (average 9.6 years). In 24 patients both lesions were diagnosed at operation only; in 8 patients both lesions were diagnosed at autopsy only; and in 33 patients one or more lesions were diagnosed both at operation and at autopsy. The distribution of the specific types of associated primary malignant neoplasms did not differ significantly from that expected in a comparable group of patients with single malignant neoplasms.

The reported data seem to establish definitely that the occurrence of an independent primary cancer of the lung in a patient with known malignant neoplastic disease at another site is not uncommon. Therefore, no solitary pulmonary lesion in a patient with a previously diagnosed cancer may be assumed to be metastatic without positive laboratory confirmation. In patients affording reasonable evidence that a primary malignancy elsewhere has been controlled, the presence of a discrete pulmonary lesion is an absolute indication for thoracotomy.

Ulcer of the Oesophagus. P. Rudström and B. Drettner. Acta chir. scandinav. 116:186-195 (no. 3) 1958-1959 (In English) [Stockholm].

The authors report on clinical pathophysiological and surgical observations made on 4 men and 4 women with solitary callous ulcer of the intrathoracic portion of the alimentary tract. The ages of the patients ranged between 37 and 75 years. The patients exhibited recurrent, severe retrosternal pain at the level of the lesion combined with a burning sensation and a feeling of obstruction to the passage of food. Dysphagia predominated, and the patients lost much weight. More than half of the 8 patients had a diaphragmatic herniation making possible reflux of the gastric contents. In 4 patients there was gastric or duodenal ulcer with marked symptoms, for which 2 of the patients had undergone an operation. In 2 patients gastric ulcer was combined with hiatus hernia. Contact between the mucous membrane of the esophagus and hydrochloric acid and pepsin from the stomach is believed to be a factor of great importance to the development of ulcerations. Therefore, surgical treatment was directed not only to removing the involved portion of the esophagus but also to resecting so large a portion of the stomach that the production of hydrochloric acid was almost entirely inhibited. Thoracotomy with resection of the 8th rib on the left side was performed. The cardial region and the lower esophagus were dissected free, and the fundus and body of the stomach as well as the lower portion of the esophagus were resected. The gastric stump was left as small as possible by means of resection of the lesser curvature in a distal direction. The proximal gastric incision was closed, and the esophagus anastomosed to the anterior wall of the stomach via a stoma. The anastomosis was secured with 2 layers of interrupted silk sutures. The suture line was covered posteriorly by the stomach and anteriorly by a flap of omentum. Despite the radical resection of the stomach, no obstruction to the passage of food was noted, nor were any nutritional difficulties recorded during the postoperative period. The majority of the patients gained weight rapidly. No serious postoperative complications occurred, and no deaths were recorded. The patients became immediately free of dysphagia, and their general condition showed rapid improvement. The results were found to be favorable on follow-up examination after an interval ranging from 1 to 7 years.

Pyloric Stenosis. J. A. Balint and M. P. Spence. Brit. M. J. 1:890-894 (April 4) 1959 [London].

The authors report on 86 men and 32 women with pyloric stenosis, defined as a condition in which obstruction to the emptying of the stomach is due to an organic lesion in the region of the pylorus. Of these 118 patients, the cause of the pyloric stenosis was established by laparotomy in 115, at autopsy in 2, and by roentgenographic examination in 1. A duodenal ulcer was the cause of stenosis in 95 patients. A gastric ulcer remote from the pylorus was the cause of obstruction in 7 patients. In 13 patients pyloric obstruction was due to carcinoma of the pyloric antrum; in 2 it was due to kinking of the duodenum which had become adherent to a chronically inflamed gallbladder; and in 1 it was due to a congenital diaphragmatic constriction at the pylorus. Vomiting attributable to pyloric stenosis occurred in all but 3 patients, being a presenting symptom in 105. A predominant pattern was discernible in 85 patients, with daily vomiting in 29, more frequent than daily in 35, and occasional in 21. Pain of ulcer type had occurred in 105 patients. Anorexia was present in 73 patients. Seventy-seven patients had lost 5 lb. (2.3 kg.) or more in weight. Diarrhea occurred in 23 patients (20%). It was usually slight, but in 6 it was severe enough to be a presenting symptom. The high incidence of offensive eructation in the patients with diarrhea suggests that stale food in the stomach leads to the production of some substance irritant to the intestine. The duration of obstructive symptoms before admission to hospital varied from one month in 37 patients to more than one year in only 14. Confirmatory physical signs associated with pyloric stenosis consisted of a gastric succussion splash in 66, of visible gastric peristalsis in 33, and of dehydration in 29. A barium-meal examination was performed on 93 patients and showed evidence of delayed emptying in 79. Anemia was common, and a raised hemoglobin level was rare. The blood urea level was raised to 50 mg. per 100 cc. or more in 50% of the patients.

The diagnosis of pyloric stenosis was reasonably certain when the following stringent major criteria were satisfied: a classic history of persistent vomiting of large amounts at times when the stomach should be empty, containing recognizable residues of food eaten some hours previously or accompanied by offensive eructation; the presence of visible gastric peristalsis; the main daily volume of the gastric residue exceeding 1,000 cc. on the first or last 3 days on which aspiration was performed; the stomach emptying by less than one-third in 2 hours, less than a half in 3 hours, or less than two-thirds in 4 hours, as estimated by the radiologist who performed the barium-meal examination. The definitive treatment was surgical in nearly all patients. There were only 2 deaths among the 92 patients operated on for pyloric stenosis due to a benign ulcer. By contrast, only 4 of the 13 patients with carcinoma left the hospital after a potential curative operation. Medical treatment, with repeated gastric aspiration or lavage, replacement of fluid and electrolyte loss, bed rest, and frequent milk feedings, although an essential preliminary to surgical treatment, was rarely tried as definitive therapy and never proved of lasting value.

Gastric Resection and Alcoholism. W. Dick, R. Fischer and G. Sautter. Deutsche med. Wchnschr. 84:311-316 (Feb. 20) 1959 (In German) [Stuttgart, Germany].

The authors point out that several years ago 2 Austrian investigators had found that every 5th inmate of a home for dipsomaniacs had undergone gastric resection, and thereafter others found even higher percentages. They then present the histories of patients from their own practice which had induced them to investigate the relationship between gastric resection and alcoholism. The authors gained the impression that from 2 to 3% of the patients who have undergone gastric resection are likely to become alcoholics to an extent that they require institutional treatment. They discuss alcohol addiction before operations on the stomach and studies on tolerance for alcohol and on alcohol resorption in patients who have undergone gastric resection.

If disease of the stomach and alcoholism have no connection, then the percentage of persons who have undergone gastric resection should be no higher in homes for alcoholics than in the general population. Exact information about this point is difficult to obtain. The investigators who first called attention to the high incidence of alcoholism in persons who had undergone gastric resection considered peptic ulcer and alcoholism as pathogenetically coordinated disturbances, pointing out that the same emotional conflict situations are found in ulcer patients and alcoholics. The 2 conditions are regarded as "equivalents," so that sometimes the ulcer patient will exchange the freedom from symptoms after the operation for alcoholism.

There is no doubt that gastric resection changes the mode of reaction to the consumption of alcohol. Improved "gastric" tolerance is accompanied by a "worsening" of "brain" tolerance for alcohol. This lack of tolerance may be responsible for the fact that some patients who have undergone gastric resection may be institutionalized for alcoholism, because, although they really are not drunkards, they had become intoxicated to a degree which would not have occurred if they still had an intact stomach. This factor of "reduced alcohol tolerance" should be impressed on patients who undergo resection and who drive motor vehicles, so as to prevent accidents. Commenting on the question whether alcoholism may lead to gastric resection, the authors say that this possibility is not remote. Alcoholism does lead to gastritis, but rarely to ulcer. Surgeons should be aware of an increased incidence of the sequels of alcoholism after gastric resection.

***Chronic Fibrous Mediastinitis and Superior Vena* Caval Obstruction Due to Histoplasmosis.** J. M. Salyer, H. N. Harrison, D. F. Winn and R. R. Taylor. Dis. Chest 35:364-377 (April) 1959 [Chicago].

The authors report on 3 men, between the ages of 25 and 30 years, and on a 30-year-old woman with bronchial or mediastinal venous obstruction due to chronic fibrous mediastinitis who were admitted to the Fitzsimons Army Hospital in Denver. The 4 patients underwent exploratory thoracotomy which revealed fibrous mediastinal lesions from which biopsy material was obtained. The lesions showed various degrees of calcification and were so extensive, obliterating anatomic planes, that pulmonary resections were technically impossible or considered unwise. In one patient the azygos vein and superior vena cava were excised, and the vena cava was replaced from the right innominate vein to the auricle by an aortic homograft. Clinical and laboratory findings with uniform gross and microscopic appearance of these intrathoracic lesions gave a sufficient basis to make a diagnosis of chronic fibrous mediastinitis due to histoplasmosis. Morphologically typical organisms of Histoplasma capsulatum were observed in the caseous material from a granulomatous lymph node in one patient, and organisms highly suggestive of such a fungus disease were found in the thick fibrous tissue obtained by biopsy from another patient. Proliferative collagenous replacement of lymph nodes renders histological and cultural confirmation of H. capsulatum difficult unless lymphoid tissue is obtained at thoracotomy before complete replacement of the granulomatous process with dense fibrous tissue. Buried within such lesions there may be found caseating granulomas which contain organisms typical of H. capsulatum. Multiple mediastinal biopsies from the other 2 patients were not conclusively diagnostic in that no lymph node showing such early collagenous replacement of necrotic foci was observed, although the typical hyalinized fibrous and calcific tissue was in abundance.

Other workers including clinicians, surgeons, and pathologists, who have reviewed the literature and their clinical experiences with chronic fibrous mediastinitis or obstruction of the superior vena cava, stated that from 15 to 50% of such lesions were secondary to chronic inflammatory diseases. Of the specific varieties, tuberculosis and syphilis always have been included or implicated. The authors suggest that a significant percentage of such lesions, considered in the past to be tuberculous, syphilitic, thrombotic, traumatic, rheumatic, cicatricial (keloid), or idiopathic in nature, were actually due to the rather uniform response of the mediastinal lymph nodes and related anatomic structures to infection with H. capsulatum.

Wound Irrigation to Prevent Local Recurrence of Cancer. R. G. Collier, R. C. Ey, G. O. McDonald and W. H. Cole. A. M. A. Arch. Surg. 78:528-534 (April) 1959 [Chicago].

The authors devised a biological animal screening procedure to assay the effectiveness of agents which could be used as wound irrigants to kill implanted cancer cells. Twelve such agents were tested in albino rats in which surgical wounds had been produced and inoculated with a cell suspension of the 256 Walker tumor. Among these agents was mechlorethamine, but it was tested only for comparison. The primary purpose of these experiments was to find a wound irrigant which was not a bone-marrow depressant. Such an irrigant could be used to irrigate the wound of a patient who also received mechlorethamine or a similar anticancer agent at the time of surgical intervention in the prophylactic or adjuvant program. A form of monoxychlorosene, Clorpactin XCB, was found to be the most effective non-bone-marrow depressing agent in preventing growth of tumors in the experimental animal screening procedure.

As a result of this study a clinical trial was started, a 1% solution of Clorpactin XCB being used to irrigate surgical wounds after radical mastectomies, radical neck dissections, and the perineal wounds of combined abdominoperineal resections. The wound is irrigated every 45 minutes during the operation with 250 cc. of a 1% solution of Clorpactin XCB made up in cool isotonic sodium chloride solution. The solution is allowed to remain in contact with the tissues for 3 minutes at each irrigation period. At the conclusion of the operation, just before the skin flaps are sutured, the wound again is irrigated with 500 cc. of the solution. The use of this wound irrigant should accompany adequate cancer surgery, and should not be construed as a replacement or a substitute for well-established and proved surgical procedures.

Hyperparathyroidism and Gastroduodenal Ulcer. J. Hellström. Acta chir. scandinav. 116:207-221 (no. 3) 1958-1959 (In English) [Stockholm].

The author evaluated the relation between hyperparathyroidism and peptic ulcer on the basis of data gathered from the literature as well as from personal observations on 121 patients with hyperparathyroidism. In 14 of the 121 patients (10 men and 4 women), a gastroduodenal ulcer was definitely present. The incidence of peptic ulcer was 28.6% in the men and 4.6% in the women. The age at which ulcer symptoms first appeared varied between 20 and 51 years. In most cases the ulcer symptoms started long before hyperparathyroidism was diagnosed. In all the 14 patients except one, the primary ulcer was in the duodenum. The pathoanatomic changes in the parathyroids consisted of a single adenoma in 13 patients and of primary hyperplasia of all the glands in 1 patient. Parathyroidectomy was performed on all 14 patients. In 10 patients the ulcer healed postoperatively; the condition of 3 patients improved and that of 1 remained unchanged.

Analysis of the data gathered from the literature and from the series of 121 patients revealed that the incidence of gastroduodenal peptic ulcer was greatly raised in patients with hyperparathyroidism. In some patients the relation between hyperparathyroidism and peptic ulcer was a coincidence. In other patients there was some relation between hyperparathyroidism and peptic ulcer, probably chiefly in the form of an unfavorable influence on healing of the ulcer. Finally, in some patients other endocrine factors, particularly in the form of ulcerogenic tumors of the pancreas, affect the development of peptic ulcer in patients with hyperparathyroidism.

Cancer of the Terminal Portion of the Large Intestine: Diagnostic and Therapeutic Aspects. J. Bastien, J. Boy and S. Segal. Strasbourg méd. 10:1-20 (Jan.) 1959 (In French) [Strasbourg, France].

The authors distinguish 3 types of cancer: small cancers whose dimensions do not exceed 2.5 cm., polypoid sessile tumor, and the most frequent type, infiltrating or stenosing ulcerated cancer for which radical treatment is indicated. Three aspects from cytological study of cells forming the neoplasm are the abundance of mitoses, the differences of density in chromatin from one cell to another, and finally the search for modifications of volume or number of nucleoli. These signs are absent in tumors of the villous type and in doubtful polyps. The following rules of conduct in treatment of cancer of the terminal portion of the large intestine were based on 121 cancers which the authors had treated: 1. For cancer beyond the possibility of surgical cure, only colostomy can be considered, completed by coagulation when it is possible. 2. A small tumor whose diameter does not exceed 2.5 cm. should be treated according to its high or low location by an abdominal resection alone or by radiotherapy with "contact doses." 3. Ulcerative cancer will have different therapy according to whether its seat permits conservation of the sphincter ani. All cancers below 12 cm. call for an abdominoperineal resection.

The authors paid particular attention to fast-developing cancer, and it is in order to lessen it that they employed definitive ileostomy and one or several sessions of contact radiotherapy. In more favorable cases contact radiotherapy alone was used in order to arrest progressing cancer. When the tumor is at the rectosigmoid angle or a little above it, it is removed by a resection performed by the abdominal route; this is preceded, when it is accepted, by a temporary colostomy.

The Experimental Development of Pseudomembranous Enterocolitis. T. L. Tan, C. T. Drake, M. J. Jacobson and J. van Prohaska. Surg. Gynec. & Obst. 108:415-420 (April) 1959 [Chicago].

Even though Staphylococcus pyogenes var. aureus has been isolated in most reported cases of pseudomembranous enterocolitis, there is still doubt about the cause of the disease, because obviously unrelating derangements of colonic flora have been reported in patients with the disease. The authors therefore reproduced enterocolitis in animals by a pure culture of Staph. aureus isolated from a patient with pseudomembranous enterocolitis. Chinchillas were used for the experimental studies, because they have been known to contract enterocolitis spontaneously after prolonged ingestion of certain antibiotics, particularly Aureomycin. When the inoculated chinchilla died, the same micro-organism was reisolated in pure culture from its intestine. In addition, the reisolated staphylococcus yielded enterotoxin poisonous to another animal. Thus, the experiment fulfills the 4 postulates of Koch. Strains of Staph. aureus isolated from patients with food poisoning or from those with pseudomembranous enterocolitis were tested. All these strains were capable of producing enterotoxin and were tested repeatedly for the content of enterotoxin.

The experiments were carried out on 12 chinchillas, which received their standard diet of cabbage, lettuce, and carrots. Cultures of their normal stools were obtained and sensitivity reactions to various antibiotics were determined. Guided by the sensitivity tests, the animals were given 50 mg. of oxytetracycline twice daily or mixtures containing 12.5 mg. of Aureomycin, 12.5 mg. of oxytetracycline, and 25 mg. of Gantrisin, or 12.5 mg. of oxytetracycline and 25 mg. of Gantrisin. The oral administration of this antibiotic mixture was maintained for 5 or more days. Beginning on the 6th day, the animals received a suspension of pure culture of Staph. aureus in 2 daily doses by mouth. In the first group of 3 animals the antibiotic mixture was continued along with the oral administration of the suspension of the micro-organism. In the second group of 2 animals the antibiotic was withdrawn on the 6th day, and from then on the animals received only the suspension of pure culture of staphylococcus. All experimental animals became sick. The untreated animals remained well. The principal symptoms were anorexia, lethargy, and occasional diarrhea. Particularly interesting observations were made on a third group of 3 chinchillas. They improved, but when they were retested after an interval, they died apparently as the result of the administration of the antibiotic, before the staphylococcus suspension was given. Explanations for this phenomenon are discussed.

The significant gross findings at autopsy were marked distention of the stomach, duodenum, and the entire small intestine. The principal microscopic changes observed were edema of the gastrointestinal tract, leukocytic infiltration of the mucosa, submucosa, and muscularis, superficial ulcerations, and passive congestion; in numerous segments the mucosa was completely sloughed off. In particular, the stomach showed leukocytic infiltration, thinning of the mucosa, and loss of the normal villous structures. The duodenum showed marked loss of mucosa with ulcerations, heavy leukocytic infiltrations, and fibrinomucous exudate or pseudomembrane in the lumen. The colon showed minimal microscopic changes, but even here one could discern changes compatible with inflammatory colitis. The authors conclude that the etiological agent of pseudomembranous enterocolitis is the enterotoxin-producing Staphylococcus organism.

Fractures of the Femoral Shaft in Children with Special Reference to Subsequent Overgrowth. B. Barfod and J. Christensen. Acta chir. scandinav. 116:235-250 (no. 3) 1958-1959 (In English) [Stockholm].

The authors report the results of a follow-up study on fractures of the femoral shaft in 126 children, under 15 years of age, treated at the Kommunehospital and the Amtssygehus in Aarhus, Denmark, between 1945 and 1954. Follow-up examinations were performed on 114 of the 126 patients, and the observation periods ranged from 2 to 12 years. Osteosynthesis was used for 23 patients and conservative treatment for 91. The duration of treatment was longer for those subjected to osteosynthesis than for those undergoing conservative treatment. Moreover, the patients who were treated conservatively had a better end-result in the form of a smaller inequality in the length of the fractured limb and an earlier return to normal gait than was seen in those treated with osteosynthesis.

Observations have shown that fracture of the femoral shaft in children is followed by a lengthening, which amounts to as much as 3 cm. after conservative treatment and often no more than 3 cm. after osteosynthesis. The lengthening occurring after conservative treatment seems to be compensatory in nature. Of the 91 patients in this series whose fractures were treated conservatively, about 80% showed normal length, with variations not exceeding plus or minus 1 cm., at the follow-up examination. After osteosynthesis, however, overgrowth always occurred as compared with the uninjured limb, and follow-up examination revealed lengthening in excess of 1 cm. in 20 of the 23 patients. A shortening of the fractured limb amounting to 2 cm. at the most, angulation of less than 25 degrees, and absence of rotation should be the aims of therapeutic measures which are carried out conservatively. Thus, osteosynthesis is not indicated in fractures of the femoral shaft in children.

New Points of View Concerning Pathogenesis of Dupuytren's Contracture. H. Millesi. Beitr. klin. Chir. 198:1-25 (no. 1) 1959 (In German) [Munich, Germany].

Observations on 231 patients with Dupuytren's contracture, who were operated on in the department of plastic surgery of the first surgical clinic of the University in Vienna, showed that the onset of the disease occurs frequently at an advanced age. Men are more often affected than women. The 4th and 5th fingers are involved most frequently. The contracture begins with a circumscribed thickening in the palm of the hand to which the skin is fixed. The course of the disease is characterized by bouts with prolonged spontaneous intervals of arrest. Histological examination of 11 embryonal and fetal pairs of hands in various stages, of 31 hands from cadavers, and of 41 surgical specimens obtained from patients operated on for Dupuytren's contracture showed that the connective tissue system of the palm is a functionally uniform body built up by a spatial connective-tissue network with deposits of fatty tissue and interspersed collagen fiber bundles in various directions. The contracture columns correspond to the course of the fiber systems. They represent, therefore, no new formations, but thickening of previously formed fiber bundles. Normally the individual fiber bundles possess microscopically a wave-like structure and contain elastic fibers.

The operative specimens obtained from 2 patients in whom the contracture was still in an early stage showed that, at the onset of the condition, a degeneration of the elastic fibers occurs and also thickening and hyalinization of the collagen fiber bundles. Only within the thickened fiber bundle proliferation of cells develops. An autogenous sensitization to degeneratively altered collagen is to be considered the cause of this proliferation. This concept was supported by the fact that the intracutaneous injection of a suspension of autogenous contracture tissue which was given to 14 patients caused a red papule in 10 patients; the subcutaneous injection of a suspension of homogenous contracture tissue which was given to 15 patients caused a similar reaction in 12. In contrast to that, this intracutaneous test gave negative results in control persons without Dupuytren's contracture. The proposed concept of pathogenesis of the contracture explains the occurrence of the contracture in the fiber bundles which are exposed to a pulling effect, and it also explains the fact that finger contracture, which has become established, becomes worse if mechanical extension exercises are carried out for therapeutic purposes.

Synthetic Materials as Vascular Prostheses: III. Long Term Studies on Grafts of Nylon, Dacron, Orlon, and Teflon Replacing Large Blood Vessels. J. H. Harrison. Surg. Gynec. & Obst. 108:433-438 (April) 1959 [Chicago].

In a comparative study of synthetic materials as vascular prostheses under various conditions, grafts of nylon, Dacron, Orlon, Teflon, and Ivalon Sponge were inserted into defects created in the thoracic aortas of 84 dogs. The results with these after 1 or 2 years have been previously reported. There was rapid breakdown of the Ivalon Sponge, leading to aneurysms and rupture of the grafts. Nylon lost 80% of its original strength by 6 months and up to 95% after 2 years. No complications were encountered with grafts of Orlon, Dacron, or Teflon after one year, and the materials lost little of their original strength. In this paper the author presents observations on 10 of the original group of 84 dogs observed for periods up to 3 years.

Maintenance of patency was no problem, as only one graft became occluded and this secondary to a hematoma. There was delayed bleeding through the interstices of grafts of nylon, Dacron, and Orlon resulting in encapsulated hematomas. Nylon continued to lose strength. Complete breakdown resulted with rupture in 2 grafts. Dacron, Orlon, and Teflon maintained most of their strength during the period of observation. Grafts made of Teflon were the only ones in which complications did not occur when observed for 2 years. In addition, Teflon should, due to its greater chemical inertness, be expected to maintain its strength over a longer period of time. It is considered the synthetic material of choice as a vascular prosthesis and superior to homografts for replacing vessels larger than 9 mm. in diameter.

Left-sided Pneumatosis Coli. C. A. Neumeister. Minnesota Med. 42:407-408 (April) 1959 [St. Paul].

The author reports the case of a 49-year-old woman with intestinal pneumatosis, a rare condition of unknown causation which is now becoming more generally recognized. The patient complained of abdominal distress of an aching type. Sigmoidoscopic examination revealed what appeared to be multiple polypoid lesions beginning at the 8-cm. level. Barium-enema studies revealed multiple polyps throughout the descending and the sigmoid colon. At laparotomy and colotomy no polyps were found, and the diagnosis of left-sided pneumatosis was definitely established. Two months after the surgical intervention sigmoidoscopic examination revealed almost complete disappearance of the intramural cysts. The patient was asymptomatic.

The pathological picture is best explained by the theory that gas distending the lymphatics with blockage of the lymphatics causes the cystic distention in the submucous and subserous layers of the intestine. The composition of the gas in the cysts has apparently never been determined. The inflammatory reaction surrounding the cysts varies from the acute type with leukocytic infiltration to granulomatous changes with epithelioid cells and giant cells of the multinucleated type. Of the concepts proposed as to the causation of pneumatosis, the nutritional deficiency theory is the only one supported by experimental evidence. The syndrome is self-limited and does not require any specific treatment unless complications supervene. Once the diagnosis of pneumatosis is made, the treatment is expectant, and one can expect spontaneous remission.

NEUROLOGY & PSYCHIATRY

Course of Spinal Amyotrophy of Childhood. D. Furtado. Arq. pat. 30:522-532 (Nov.) 1958 (In Portuguese) [Palhava, Lisbon].

According to the classical conception, spinal amyotrophy of the Werding-Hoffmann type begins in early life and ends fatally in from a few months to 4 years. It is a type of familial and progressive disease. A case of the disease compatible with life of the patient and with regression of paralysis is reported. The patient was normal up to the age of one year, when he already walked by himself. Paralysis appeared at that age and became acute. The child was observed for the first time at the age of 2 years with complete paralysis, amyotonia, and amyotrophy. Cephaloplegia was complete, although the facial muscles were normal and talking and swallowing were normal. Respiration was of the abdominal type. Biopsy and electromyograms showed changes of progressive spinal amyotrophy. The patient was able to move only the hands and feet.

The patient's parents were first cousins. Some members of the family had neuropathic disorders, but an older sister was normal. The patient was observed for 12 years, up to the age of 14. Early diseases of childhood and infections were controlled with antibiotics and sulfanilamides. The treatment for the muscular disease consisted of mild physical therapy, with passive movements and stimulation of active movements. A slow but constant regression of paralysis of certain muscles became evident between the ages of 5 and 12 years; this became a frank regression between the ages of 12 and 14 years. The patient is now able to swim the span of a pond unaided. He can be seated in a chair and is able to write and to feed himself. Somatic and sexual development is normal. The intelligence quotient is normal, and the patient today is an advanced student in high school.

The author points out that the prognosis of progressive spinal amyotrophy depends on the form, either typical (severe) or benign. A frank regression of paralysis and indefinite prolongation of the life span correspond to the benign form of the disease. This was the form in the case reported.

Circumscribed Cerebral Thrombophlebitis. G. Dalle Ore and R. Da Pian. Minerva med. 50:519-526 (Feb. 21) 1959 (In Italian) [Turin, Italy].

The authors discuss the clinical picture of acute circumscribed cerebral thrombophlebitis terminating in a complete remission in 2 boys, 9 and 10 years of age. The disease was attributed to the exacerbation of a mild, chronic otitis. A pain more intense than usual developed in the affected ear of each boy 20 and 15 days, respectively, before admission. An episode of intense headache, accompanied by unmanageable vomiting and followed by fever, convulsive seizures, motor and speech deficiency, and coma, took place in both patients 2 and 3 days, respectively, before admission. This state persisted for 2 or 3 days. The disease resolved gradually and slowly in one patient, and rapidly in the other, after the patients had received a high-dosage treatment of specific antibiotics and systemic drugs. The recovery was complete in both patients, without any neurological sequelae, and they were discharged on the 40th hospital day.

The electroencephalograms of both patients were obtained while the neurological symptoms were subsiding. The pathological changes recorded by electroencephalography involved both hemispheres in one boy and the affected hemisphere only in the other. These changes, although in less degree, were also observable on the 30th hospital day. Arteriographic findings were negative except for a slight displacement of the anterior cerebral artery on the frontal plane in one patient and the enlargement of venous vessels in the other. Spinal canal puncture revealed no abnormality in one boy and only a slight increase of white blood cells in the other. Examination of the fundus oculi was negative in both patients except for enlargement of the veins. Despite the absence of any neurological lesion, the correct diagnosis was made in the patient who was first hospitalized during resolution of the disease. The correct diagnosis in the patient who was subsequently hospitalized was easier and was made more promptly, because the neurological symptoms were subsiding at the time of admission and in view of the acquired experience with the first patient.

Poliomyelitis in the Sudan. M. A. Haseeb. J. Trop. Med. 62:45-46 (Feb.) 1959 [London].

The author believes that the immunological status of a population should be assessed before decisions are made as to whether vaccination against poliomyelitis should be carried out or not, and if so to what extent. In the absence of reliable statistics, useful data may in certain circumstances be obtained from serologic surveys. This communication is concerned with the results of serologic tests performed on 2 groups of Sudanese children. One group consisted of 48 children from the rural region of Kassala, and the other group consisted of 46 children from the urban area of Khartoum. The children ranged in age from 18 months to 14 years. All serums neutralized 1, 2, or all 3 types of poliomyelitis virus. The pattern of poliomyelitis in the Sudan conforms with that prevailing in the countries of Africa previously studied. The incidence is high early in life, but the morbidity is low, and the disease seldom ends fatally. The author concludes that mass vaccination against poliomyelitis is not indicated at present in the Sudan.

Investigation of Families with Two or More Mentally Defective Siblings: Clinical Observations. S. W. Wright, G. Tarjan, and L. Eyer. A. M. A. J. Dis. Child. 97:445-463 (April) 1959 [Chicago].

Several genetically determined biochemical abnormalities, such as phenylketonuria and aminoaciduria, associated with mental defect have been described by other authors in siblings. These observations suggest that among members of families with 2 or more defective siblings the likelihood is high that there are some persons with an inherited biochemical defect. In an attempt to prove this concept, the authors carried out a study at the Pacific State Hospital, an institution for the mentally defective in Pomona, Calif., in which 61 families with 2 or more mentally defective siblings were identified. Clinical observations on the siblings and their parents are reported; special biochemical observations will be the subject of a later report. There were 319 siblings in the 61 families. Of the 319 siblings, 107 were of normal mentality; the intellectual status was unknown in 23, and in 28 the mental status was subnormal; 13 siblings were known to be mentally defective but had not been institutionalized; and the remaining 148 siblings had a mental defect for which they had been institutionalized. The groups of defective siblings ranged from one in which the defective siblings had intelligence quotients of 87 and 71, respectively, to one with 3 siblings with a heredodegenerative disorder and intelligence quotients below 5. In 14 families there were defective twins; 13 sets were of the same sex, and 1 set was mixed.

Of the 319 siblings, 185 were males, of whom 108 (57%) were defective, and 134 were females, of whom 53 (47%) were defective. The 2:1 ratio of males to females in this group is significantly higher than the 3:2 male to female ratio in the over-all hospital population. There were 26 families with only males affected; 15 of these had normal female siblings. In 6 families only females were defective, and in the remaining 29 families there were both male and female defective patients. Over 50% of the fathers and mothers had evidence of inadequate intellectual status or disturbed social behavior with or without institutionalization.

Disorders with a known biochemical abnormality were found in 5 families. These included 4 defective sibling groups with phenylketonuria and 1 with lipochondrodystrophy (gargoylism). Among the remaining 56 groups, significant somatic, neuropathological, and psychopathological findings were noted in 7 families. It is possible that a simple type of inheritance may account for the mental defect in some of these groups. They included individual groups with ectodermal dysplasia (hypotrichosis), true microcephaly, congenital cataracts, Roussy-Lévy syndrome (a variant of Friedreich's disease), heredodegenerative disorder, schizophrenic symptomatology, and a possible sex-linked disorder with severe mental defect. A definite clinical diagnosis was made in 5 additional groups. They included 2 groups with Mongolism and 2 with prematurity and retrolental fibroplasia; in the 5th group one sibling was defective as a result of postnatal infection and the other as a result of severe trauma. This "defective sibling" method appears to be of value in isolating for further study a group of patients with an increased likelihood of a genetically determined biochemical disorder.

Serological Studies of the Poliomyelitis Epidemic in Huskerville, Neb. W. E. Engelhard and P. M. Bancroft. A. M. A. J. Dis. Child. 97:409-417 (April) 1959 [Chicago].

An abrupt, severe outbreak of poliomyelitis, which occurred in Huskerville, Neb., in 1952, was reported by the authors in a previous paper in The Journal, June 22, 1957, page 836. This epidemic of poliomyelitis was explosive, running its course in 5 weeks with 20 confirmed clinical paralytic cases and 31 nonparalytic cases among a population of 1,142 persons. The present report describes the distribution of types 1, 2, and 3 poliomyelitis neutralizing antibodies in the serums of Huskerville residents, who had had paralytic and nonparalytic symptoms in the course of the 1952 epidemic, and in the serums of 270 children in Huskerville, who did not have clinical poliomyelitis in 1952 and served as controls. The serologic findings showed the causative agent to be type 1 virus. Type 1 virus was not restricted in its distribution to the high-incidence area but was disseminated throughout the community. The incidence of involvement was greater in the area of high incidence of clinical disease.

Distribution of poliomyelitis viruses in the post-epidemic control group, consisting of children, between the ages of 6 months and 13 years, who moved into Huskerville 12 to 18 months after the epidemic, followed the usual pattern. Neutralizing antibodies were absent in the younger age group, while they appeared with increasing frequency in succeeding age groups. Observations, when compared with the control group of epidemic exposure on antibody levels, showed marked increase of type 1, moderate increase of type 2, and little change of type 3 antibodies. High-titer poliomyelitis neutralizing antibodies were shown 2 years after the epidemic. No differences in immune response were observed among paralytic and nonparalytic cases. However, type 1 virus proved to be the most antigenic. Very limited findings suggest the absence of cross immunity with the 3 types of poliomyelitis, and ability to produce neutralizing viral antibodies seems to develop with age.

GYNECOLOGY & OBSTETRICS

Abdominal Cesarean Section for Previous Tumor Constituted by Malformation of Uterus. M. R. Giron. Rev. españ. obst. y ginec. 15:342-344 (Nov.-Dec.) 1958 (In Spanish) [Valencia, Spain].

A 33-year-old woman was hospitalized at full term of her third pregnancy. She had previously had 2 children, now 7 and 4 years old, respectively, who were delivered normally. On hospitalization the patient had regular contractions every 2 minutes, lasting for 20 or 30 seconds. The fetal heart beat was normal, and palpation revealed that the fetus presented normally. The neck of the uterus was dilated 2 cm., but it was pushed toward the back of the pubis by a tumor located in the Douglas cul-de-sac. The tumor could not be mobilized, and it prevented engagement of the fetal head. Cesarean section was accordingly performed, after which it was observed that the tumor could be moved out from the cul-de-sac. The supposed tumor proved to be the part of a double uterus which during pregnancy folded behind the pregnant part, occupied the Douglas cul-de-sac, and acted as if it were a growth, causing dystocia. Both parts of the uterus were left undisturbed in the belief that, when their anatomic relationship would have been reestablished, the uterus would appear as made up of 2 symmetrical horns, divided by a slight partition and having a common neck. Both halves of the uterus were of the same size and capacity. Which one had been occupied by the fetuses in the 2 previous deliveries was unknown.

Smears, Colposcopy, Biopsies in the Early Diagnosis of Cancer of the Uterine Cervix on the Basis of 892 Cases. J. Mathieu and P. Villedieu. Lyon chir. 55:25-35 (Jan.) 1959 (In French) [Paris].

The results obtained by colposcopy and vaginal cytological studies in 892 patients between September, 1955, and November, 1957, have been analyzed in an attempt to determine the value of these procedures in the early diagnosis of cervical cancer. The clinical course of the patient, which is the only absolute criterion of accuracy, was used in evaluating the findings. Study of 638 vaginal smears yielded 18 false-positive or false-negative readings, or a percentage of error of 2.8%. Only 10 errors were recorded in 1,178 colposcopies, making a much smaller percentage of error. The simultaneous use of both methods, which the authors advocate, has proved accurate as judged by the clinical course in every case but one, that of a patient with an endocervical neoplasm who had previously been given radium treatment in an unknown dosage. The patient refused further radium therapy, which was advised because of a suggestive smear, and was later found to have a neoplasm of the isthmus.

The biopsy findings were never inconsistent with the later course. The comparatively small number of biopsies (171) in this series reflects the authors' increasing confidence in the reliability of the findings obtained by simultaneous study of the vaginal cytology and colposcopy. Biopsy is resorted to without delay, however, when the colposcopic findings are doubtful or when the clinical picture is at variance with the results of the investigative procedures.

Another aspect of the question of early diagnosis of cervical cancer is the problem posed by epithelioma in situ and its treatment. The authors have been much more impressed by the risk of true invasive cancer at some distance from the area from which the biopsy specimens are obtained and by the frequency of secondary degeneration in the cervix after local treatment than by certain figures published in the literature that seem favorable to the regression and propitious course of neoplasms in situ treated locally. They, therefore, believe that hysterectomy is advisable in patients in the neighborhood of the menopause. Greater circumspection and a more conservative attitude seem, however, to be warranted at present in regard to the findings in younger women.

Hazards of Abdominal Roentgenograms in Pregnant Women: How to Reduce the Risk of Irradiation to the Fetus During Radiopelvimetry? P. Magnin. Presse méd. 67:254-256 (Feb. 7) 1959 (In French) [Paris].

A study carried out by Miss Stewart and co-workers in Great Britain between 1953 and 1955 showed that of 1,500 children, aged less than 10 years, who died of leukemia and of malignant tumors, a large number had been subjected to irradiation in utero during radiopelvimetry of the mother. The proportion of children thus irradiated was nearly twice as great as that found in a rigidly selected control group. The hazard seemed to be 3 times as great when the abdominal roentgenograms were made in the first half of pregnancy as it was when they were made later, and the risk seemed to increase in proportion to the number of exposures.

The legitimate use of radiopelvimetry is not questioned because, among 1,000 pregnant women on whom abdominal roentgenography was performed in France, not one case of leukemia or of malignant disease occurred which could be attributed to radiation. The author believes that the risk of not recognizing a pelvic narrowing has much graver consequences than radiopelvimetry. Precautions should be taken to reduce to a minimum the radiation hazards to the fetus while performing radiopelvimetry on the mother. Abdominal roentgenography should not be performed at the beginning, but only during the last weeks of pregnancy when the relationship of the fetal head to the maternal pelvis can be demonstrated. The author shows by diagrams that the amount of exposure of the fetus depends greatly on the position of the mother during radiopelvimetry, a fact which is borne out by previously published measurements by other investigators.

PEDIATRICS

Electroencephalographic Study of Tuberculous Meningitis in Children, Particularly of Those Treated Only with Isoniazid. A. Colarizi and G. Canova. Helvet. paediat. acta 13:204-217 (Aug.) 1958 (In French) [Basel, Switzerland].

The authors report clinical and electroencephalographic studies on 17 children with tuberculous meningitis, who were treated only with isoniazid in doses ranging from 15 to 30 mg. per kilogram of body weight daily. The drug was usually given by mouth. In only 3 of the children was it also given during the first few weeks by the intraspinal route. Three of the 17 children died during the first few days, but the other 14 survived without neuropsychiatric sequels. Clinical cure and normalization of the electroencephalogram were more rapid and more complete in children treated only with isoniazid than in a comparable group treated earlier with streptomycin, which was usually given by intraspinal injection, alone or with other drugs. Only 2 of the 14 surviving children treated with isoniazid still showed slight electroencephalographic changes from 2 to 4 years after the onset of the tuberculous meningitis, whereas follow-up studies on 18 children who before 1953 were treated with streptomycin plus aminosalicylic acid revealed that 5 still had neuropsychiatric and 15 still had electroencephalographic disturbances.

Psychological and Somatological Examinations on Children After Tuberculous Meningitis. E. G. Huber. Helvet. paediat. acta 13:218-227 (Aug.) 1958 (In German) [Basel, Switzerland].

The author reports the results of psychological and physiological examinations on 33 children who had survived after tuberculous meningitis. Twenty-six of the children were the survivors of the 37 children treated for tuberculous meningitis at the author's clinic between 1950 and 1956; the other 7 had been treated elsewhere. The majority of the children had had tuberculous meningitis more than 5 years before, and a minimum period of 18 months had elapsed for all of them. The results of the physical examinations with regard to changes in the eyegrounds, to lesions of the cochlear and vestibular nerves, to hemiplegia, etc., corresponded largely to those reported in similar cases by other investigators. Intracranial calcifications were found not only in the severely damaged children but also in 2 children who showed no residual defects. Likewise, there was no correlation between the electroencephalographic findings and the severity of the meningitis process. All the children with somatic lesions also showed psychological deviations and derangements.

Even the 24 children who apparently had completely recovered from tuberculous meningitis had more or less severe disturbances of the autonomic nervous system and of affectivity and had some intellectual defects, as well as neuropathic and neurotic symptoms. Behavioral disturbances ranged from pronounced instability to complete lack of self-control and destruction of personality. Despite normal intelligence, many children showed a diminished power of concentration and association; some of them showed hereditary traits in the form of an exaggerated caricature. Because there seems to be a correlation between the degree of psychological disturbance and the loss of consciousness during the acute phase of the disease, the organic origin of the psychological disturbances is demonstrated, and it is possible to make a prognosis during the acute phase. It is proposed that, in order to avert the severe disturbances after tuberculous meningitis, the patient should receive mental hygiene guidance.

Problem of Enuresis: Psychopathological and Urologic Studies on a Fairly Large Series of Patients with Enuresis. A. Weber and N. Genton. Helvet. paediat. acta 13:275-291 (Oct.) 1958 (In German, with the Urologic Study in French) [Basel, Switzerland].

The authors define the term "enuresis" as uncontrolled passage of urine occurring during day and night in children over 4 years of age, most of whom also are able of normal micturition and can manage to stay dry for shorter or longer periods. Of 73 boys and 27 girls with enuresis who attended the pediatric clinic of the University in Zurich, Switzerland, 50 were subjected to a combined psychological and somatic study, and the other 50 were studied somatically only. Psychopathologically, these children with enuresis were subdivided into 4 groups as follows: 27 children with psychoreactive disturbances, 9 children who had remained infantile mentally, 4 children with organic cerebral impairment, and 8 children who were mentally normal. Two children were doubtful borderline cases. The somatic study included cystometry and urethrography in the course of micturition, in addition to general-clinical and neurological examinations. From the somatic point of view these patients were subdivided into 3 groups as follows: 17 children who were physically normal, 18 children with a functional disturbance of the bladder, and 15 children with organic changes in the genitourinary tract.

Three conclusions were drawn from these observations: 1. Enuresis may be organically conditioned in 33% of the children, which is a higher incidence than has generally been assumed. 2. Of the 27 children with a psychoreactive disturbance, 15 were somatically normal, 6 had functional disturbances, and 6 had organic impairment; these data suggest that, if the psychological examination of a patient with enuresis reveals a psychic disturbance, the enuresis must not necessarily be a symptom of this disturbance. 3. A somatic cause of the enuresis may be considered with a high degree of probability in those patients with enuresis who were found to be mentally normal. Of 8 mentally normal children with enuresis, 6 had organic impairment, and 2 had a functional disturbance. Concerning treatment, psychotherapy, in the widest sense of the term, is recommended for patients with a psychoreactive disturbance. Causal treatment is not available for children with constitutional infantilism, but symptomatic treatment with parasympathicolytic agents may be effective in some of these patients. Teaching of rhythmics in order to increase the capability for the formation of conditioned reflexes is recommended as a "method of neurological training" for children with enuresis due to organic cerebral impairment; in older children this may be combined with education aimed at calling the children's particular attention to the motor control of the bladder. Therapy must, therefore, be differentiated depending on the causation of the enuresis as revealed by combined psychological and somatic studies.

Attitude Study of Parents with Mentally Retarded Children: I. Evaluation of Parental Satisfaction with the Medical Care of a Retarded Child. R. Koch, B. V. Graliker, R. Sands and A. H. Parmelee Sr. Pediatrics 23:582-584 (March) 1959 [Springfield, Ill.].

Data about the attitudes of the parents of retarded children toward the pediatrician and the general practitioner, related specifically to diagnosis, care, and counseling concerning mental retardation, were obtained from 105 families by the clinic for the study of mental retardation at the Los Angeles Childrens Hospital. Eighty of 105 families were seen by either a pediatrician or a general practitioner; 14 were seen by a pediatrician and a general practitioner; and the retarded children of the remaining 11 families were cared for in well-baby clinics or in the outpatient department of the Childrens Hospital. Only retarded children less than one year of age at the time of referral were accepted for study.

Forty-seven per cent of the parents were satisfied with the care of the pediatrician as compared with 55% of the parents satisfied with the care of the general practitioner. The parents of 8 of the 14 children seen by a pediatrician and a general practitioner were dissatisfied with both. Five other parents in the group seen by both physicians were critical of the pediatrician but satisfied with the general practitioner, and only one parent was critical of the general practitioner but satisfied with the pediatrician. Complaints most frequently voiced regarding the pediatrician were: "He was too rushed"; "The examination was not thorough"; "Not interested in the child"; "We weren't told anything"; and "Seemed hesitant to make the diagnosis." In other cases, when a diagnosis was made, the parents felt that the pediatrician was "too blunt," "rushed us into placement," "was unfair in predicting the future," or "emphasized the effect on our other children." Criticisms expressed toward the general practitioner were essentially the same. The criticisms of medical care can thus be divided into 2 groups, namely, criticisms of what the parents were told and criticisms of how they were told.

The recorded data show that parents of retarded children frequently take their child to various physicians without satisfaction. This is probably, in large measure, due to the fact that many physicians are not well trained to cope with the problem of retardation in early infancy. The findings in this study may be related to the general practitioner's better understanding of the family, which enables him to deal more effectively with parents. Failure of the pediatrician may be due to a lack of adequate training in the field of mental retardation.

As a result of these studies, the curriculum of the department of pediatrics of the University of Southern California school of medicine has been changed to include 4 3-hour sessions concerning the problems of mental retardation. Didactic lectures have also been organized for the nursing and resident staff at the Los Angeles Childrens Hospital. Mental retardation is a subject which needs serious consideration by pediatric educators.

Familial Lymphopenia Associated with Agammaglobulinemia and Severe Moniliasis: The "Essential Lymphocytophthisis" as a Particular Form of Agammaglobulinemia of Early Infancy. R. Tobler and H. Cottier. Helvet. paediat. acta 13:313-338 (Oct.) 1958 (In German) [Basel, Switzerland].

In 1950 Glanzmann and Riniker described for the first time in 2 nursing infants, a 4-month-old girl and a 5-month-old boy, each from a different family, the aspect of a disease which is characterized by a frequent familial occurrence of an extreme lymphocyte deficiency in the peripheral blood and in the lymphatic organs, and for which the term "essential lymphocytophthisis" was proposed. The authors studied 2 siblings of the infants reported on by Glanzmann and Riniker, a 6-month-old boy (the brother of the first reported girl) and a 2½-month-old boy (the brother of the first reported boy). The absolute number of lymphocytes in all 4 children was below 1,000 in contrast to numbers varying from 5,000 to 6,000 normally observed in infants of these ages. At birth all 4 infants appeared to be healthy and strong nurslings, and the onset of the disease occurred after a few months with a mild but refractory thrush infection in the oral cavity. Later, more or less severe gastrointestinal disturbances and acute suppurative disorders, such as subcutaneous abscess, otitis media, dacryocystitis, suppurative rhinitis, and pyoderma, occurred. At the age of 2 to 6 months the disease aspect became more severe, and up to the patients' deaths, at the ages of 3½ to 7 months, a severe moniliasis with septic temperature curves and signs of bronchopneumonia predominated. In 3 of the 4 infants a generalized morbilliform rash occurred at the height of the disease. The erythrocyte sedimentation rate was only moderately increased in all the patients.

In the 2½-month-boy, the infant who was examined last, laboratory tests revealed a syndrome of lack of antibody formation with agammaglobulinemia; it seems probable that the same defect was present in the other infants. The authors do not consider the extreme lymphocyte deficiency as "phthisis," i. e., a secondary atrophy of a previously normally developed lymphatic tissue, but they tend to consider it as a primary disturbance of formation and function of the lymphoreticular apparatus. Consequently, they prefer the term "familial lymphopenia" to that of "essential lymphocytophthisis." The familial lymphopenia with agammaglobulinemia represents a particular form of agammaglobulinemia of early infancy, which differs from the previously known familial agammaglobulinemia (Bruton) by the fact that girls may also be affected and by the simultaneous occurrence of extreme lymphocyte deficiency. It could be due to a more pronounced defect of formation and function of the lymphatic tissue than that occurring in patients with common familial agammaglobulinemia. The lymphocytic as well as the plasmocytic series are deeply affected. The severe mycotic infection is the result of the disturbed defense power against infection.

Transitory Agammaglobulinemia of Early Infancy: Delayed Occurrence of Gamma Globulins and Specific Beta-2 Globulins. R. Tobler. Helvet. paediat. acta 13:339-346 (Oct.) 1958 (In German) [Basel, Switzerland].

The author reports on a 12-month-old infant who was hospitalized for several attacks of pharyngitis with high fever, morbilliform rash, swelling of cervical lymph nodes, enlargement of liver and spleen, and edema of face, hands, and feet. After 2 months of hospitalization the infant was discharged, and at the age of 18 months he again had 2 attacks of fever with erythroderma and edema of feet and hands. Serologic studies were done shortly after the patient's admission to hospital with the aid of paper electrophoresis which revealed complete absence of gamma globulins; the antiglobulin inhibition test showed that the gamma globulins were reduced to about 60 mg. per 100 cc., a value which was considerably lower than that to be expected normally (450 mg. per 100 cc.) at this age. Isoagglutinins could not be detected. Up to the age of 14 months, the infant thus presented the clinical picture of agammaglobulinemia with lack of antibodies. While in the hospital, he was treated for a short period with tetracycline (Achromycin), and on the day of discharge he was given an intramuscular injection of 10 cc. of gamma globulin.

The patient was followed up for 7 months after his discharge. Serologic studies repeated at 3-month and 7-month intervals revealed a delayed appearance of gamma globulins and beta-2A and beta-2M globulins. The patient was given 2 additional gamma globulin injections 1 month and 7 months after his discharge. The reported observations proved again that the diagnosis "agammaglobulinemia with lack of antibodies" in nursing infants can only be made when the child has been observed for a sufficient length of time, since this condition can easily be mistaken for the physiological hypogammaglobulinemia present at this age, and particularly for the transitory agammaglobulinemia of early infancy.

Chronic Lead Poisoning: A Review of Seven Years' Experience at the Children's Hospital, District of Columbia. G. J. Cohen and W. E. Ahrens. J. Pediat. 54:271-284 (March) 1959 [St. Louis].

The authors report on 43 children with chronic lead poisoning, who were admitted to the Children's Hospital in Washington, D. C., during the period from 1950 through 1956. Most of the children were between the ages of 1 and 3 years. Of the 43 patients, the cases of 38 were diagnosed during the months of May through October. No cases of acute lead poisoning, such as are caused by inhalation of lead fumes, have been observed. Twelve of the 43 children were asymptomatic, 14 presented clinical symptoms without encephalitis, while 8 demonstrated mild and 9 severe encephalitis. The asymptomatic patients were children who had no apparent sign or symptom of lead intoxication, but, during study of families of patients with plumbism or during study for other symptoms, these children were discovered to have a significant accumulation of lead within their bodies. The patients with simple lead intoxication had anemia and gastrointestinal complaints, such as cramps or constipation. The patients with severe encephalitis had prolonged convulsions or coma for as long as 24 to 48 hours, while the patients with mild encephalitis had central nervous symptoms and signs not including those of severe encephalitis. Six of the 43 patients had marked pallor on admission, which focused attention on the hematopoietic system. An observation that deserves particular emphasis was the absence of lead lines on the gums in all the patients.

When a history of pica is sought in children with chronic lead poisoning, it is almost always found. Forty of the 43 patients had a positive history of pica. Siblings of 18 children and mothers of 4 children also demonstrated pica. Pica in these children resembled an addiction and was usually selective for a particular substance. In contrast, indiscriminate pica was seen in this series only in children with severe brain damage. The 2 most helpful diagnostic procedures, other than lead determinations, were hematological and roentgenologic studies. Hematological studies on admission were abnormal in 37 of the 43 patients. Thirty-five children presented anemia, 29 basophilic stippling, and 23 eosinophilia. It is interesting to note that not all the children with lead poisoning showed stippled red blood cells; of those who did, one-third showed stippled red blood cells only after repeated smears were examined. Roentgenologic studies revealed increased metaphysial densities suggestive of lead poisoning in 34 of 37 long bone roentgenograms, in 1 chest roentgenogram, in 1 pelvic roentgenogram, and in 4 skull roentgenograms.

This group of 43 patients was treated with ethylenediaminetetraacetic acid (EDTA) administered either intravenously or subcutaneously in the standard dose of 30 mg. per kilogram. It is believed that EDTA combines with lead only in body fluids and soft tissues; a rest period between courses of treatment has, therefore, been suggested to allow the lead in the bone to reestablish equilibrium with the lead-depleted soft tissues. Thus, EDTA was given for 5 days, withdrawn for 3 days, and then repeated for 5 days. No evidence of local or systemic toxicity from EDTA has been noted. In general, treatment has been dictated by the clinical status of the individual, since the results of the chemical studies for lead were usually not reported for 1 or 2 weeks and then frequently did not correlate well with the severity of the symptoms. Intensive supportive nursing care, parenterally administered anticonvulsants, restricted fluids, and EDTA have been the mainstays of therapy.

Three of the 43 children died (all with severe encephalopathy) after an average of 2⅓ days of hospitalization. Eleven of the patients have been lost to follow-up. Of the remaining 29 patients, 16 are considered well, 5 present moderate residuals, and 8 have severe residuals. The high incidence of residuals (45%) of neurological and psychiatric nature deserves serious consideration. It is suggested that counseling directed at cessation of pica seems to be an effective tool in prevention of continued lead poisoning. Perhaps even more important are the roles of private physicians and public health authorities in preventing the occurrence of this dangerous disease through education of the public, inspection and proper repair of substandard housing, and more stringent laws regarding lead-containing paints.

Infantile Spasms and Hypsarrhythmia. B. D. Bower and P. M. Jeavons. Lancet 1:605-609 (March 21) 1959 [London].

The authors report on 22 infants, between the ages of 1 and 17 months, with spasms, who attended the Children's Hospital in Birmingham, England, between January, 1955, and December, 1957. All the patients except one had had the first spasm before the age of 10 months, and in 14 it occurred between 4 and 8 months. There were 15 patients with flexor spasms and 7 with extensor spasms as the presenting feature. The spasms were generalized, rapid, and brief. In some patients the spasm was followed by a cry, and it was often repeated to form a series. Definite mental retardation, often severe, was almost invariably associated with the spasms. In 11 patients there was a history of prenatal or perinatal cerebral damage, and the mental development was usually retarded from birth; physical abnormalities were found in 8 of these patients. In the remaining 11 patients the causation of the spasms was unknown, and in these children mental development was usually normal up to the time of the first spasm. Routine anticonvulsant therapy was disappointing. Chlortetracycline produced a temporary remission or reduction in the number of spasms in 5 patients, and in 1 other patient the remission was permanent; the latter was the only patient who showed mental improvement after the drugs administration. One patient died at home at the early age of 2 years and 9 months. Most of the survivors remained pathetically unchanged as idiots or imbeciles.

The electroencephalographic recordings of the patients with infantile spasms were almost always abnormal, but definite hypsarrhythmia (a term coined by Gibbs and Gibbs in 1952 for a grossly abnormal encephalographic pattern marked by very high-voltage, random, slow waves and spikes in all cortical areas, giving the impression of a nearly total disorganization of cortical voltage regulation) was found in only 50% of the first records; the others showed an epileptic abnormality which was often severe. By contrast, more than 50% of the patients with epilepsy (not infantile spasms) in the same age-group have a normal electroencephalogram, and a hypsarrhythmic record is rare. Although a nonhypsarrhythmic, epileptic record may be found in patients with infantile spasms, electroencephalographic examination of suspected patients is useful, for a normal record is strongly against the diagnosis, while a hypsarrhythmic one is very much in favor of it.

Essential Hypertension in Childhood: A Clinical Contribution. B. Fantuzzi and N. Svilokos. Minerva pediat. 11:69-77 (Feb. 4) 1959 (In Italian) [Turin, Italy].

The authors discuss a case of benign essential hypertension in a 6-year-old girl with a family history of hypertension. Arterial hypertension, associated with sudden pallor, headache, and vertigo, developed a month after an adenotonsillectomy at the age of 4. The episodes, which subsequently included vomiting, were repeated once a week, and they soon took place daily. The maximum arterial blood pressure oscillated between 160 and 200 mm. Hg. Although there was no evidence of a lesion in the urinary tract, the patient had been treated for renal hypertension before admission. During a 54-day hospitalization she received Hydergine, a hypotensive compound consisting of dihydroergocornine, dihydroergocryptine, and dihydroergocristine. Hypertension persisted during and after hospitalization, with maximum basal values from 155 to 160 mm. Hg and minimum basal values from 95 to 115 mm. Hg. Laboratory findings excluded the presence of a renal lesion, pheochromocytoma, aortic coarctation or other cardiovascular malformations, and intracranial tumor.

In differentiating between benign and malignant arterial hypertension, the authors are more inclined toward the diagnosis of the benign form in this patient for the following reasons: 1. The arterial pressure never exceeded, except under emotional stress, the values of 160/115 mm. Hg. 2. A marked cardiac hypertrophy was absent on clinical, roentgenologic, and electrocardiographic examinations. 3. The level of azotemia persisted within the normal values. 4. There was no evidence of angiospastic retinitis. 5. Maximum arterial hypertension from 150 to 160 mm. Hg persisted for 6 years after discharge. 6. A slight daily headache was present, but there was no recurrence of vomiting and vertigo. 7. There was partial but durable response to the hypotensive medicament, which was administered for a short time.

The Family Physician and the Mentally Retarded Child. E. H. Watson. Postgrad. Med. 25:301-309 (March) 1959 [Minneapolis].

The family physician must summon all his skill as a counselor when he delivers a deformed or mentally defective child or is consulted about mental retardation. In the case of Mongolism or extreme microcephalia, it is rather evident from the beginning that the child's future, so far as mental development is concerned, can never be normal. However, so long as the presence of one of these abnormalities is only suspected, the best course is to put a carefully worded note on the infant's chart, with an outline of a definite plan to continue observations and to get consultation as needed to make a definite diagnosis, before acquainting the parents with the strong probability of mental defectiveness. It often requires all the art of the practice of medicine to avoid the appearance of inconclusiveness or evasiveness, on the one hand, and the unwarranted arousing of parental fears for the future development of their child, on the other hand. Failure of the infant to cry, suck, and feed normally shortly after birth may serve as a warning to the physician. The appearance of abnormal signs, such as cyanosis, twitching, or frank convulsive seizures, is ominous, but does not necessarily indicate that the central nervous system is abnormal or that it has been damaged beyond complete recovery.

Growth and development during the first few weeks and months proceed rapidly, and the experienced physician should be able to recognize signs of delay of development by the time the child is 3 or 4 months old. The monthly checkup should include observations and a notation on the chart of the child's approximate developmental stage. There is more than one reason for failure of mental growth and development to proceed in a normal fashion. In order that a correct and complete diagnosis may be made, the physician should keep in mind the various causes of mental deficiency (such as hereditary and prenatal causes, metabolic disorders, cranial maldevelopment, cerebral injury, and degenerative disorders) and of pseudomental deficiency, a term used to designate the condition of a child who is not behaving in a normal manner, due to sensory defects, cerebral palsy, chronic illness, emotional disturbance, psychosis, and environmental retardation, but who subsequently is not found to be mentally retarded. The author has found the experienced psychologist of the greatest aid in helping distinguish the mentally retarded child from the pseudomentally retarded one, and also to distinguish a child with a brain injury from the simple, genetically mentally inferior child. Often the services of an otologist or ophthalmologist may be needed in order that the child's hearing or sight may be accurately evaluated. There are state and national agencies on which the physician can call for help and advice to the parents of the deaf or blind preschool child.

It appears to be a conservative estimate that 60% or more of mentally defective children are so because of heredity. It is necessary to tell any parents of a defective child that the fact that they have produced a defective child, whether it be on the basis of genetics, isoimmunization, or unfavorable placental implantation, has statistically reduced their chances of producing normal children in the future. Answers to questions commonly asked by parents of mentally retarded children are reviewed.

Acute Leukemia in Childhood and Its Treatment. L. Tuuteri, M. Donner and R. Wegelius. Ann. paediat. Fenniae 5:39-45 (no. 1) 1959 (In English) [Helsinki].

The histories of 180 children with acute leukemia, ranging in age from birth to 15 years, who were treated at the Children's Hospital in Helsinki during 1950-1957, were reviewed in order to evaluate the results of specific therapy in leukemia. The patients were divided according to their treatment into 3 groups. The first group consisted of 100 children, most of whom were hospitalized during the earlier years of the study. These children were subjected to transfusions and other supportive therapy; antibiotics and sulfonamides were given to some patients, but none received specific drugs. The average duration of life in this group was 3.7 months. The second group of 33 children received chiefly folic acid antagonists, and steroids were given to only a few patients. The treatment in most patients was of short duration, and maintenance therapy was not consistently given. The average survival in this group was 4.7 months. The third group of 47 children, the majority of whom were treated during the last 2 years of this study, received a combined treatment with steroids and antimetabolites. The survival of this group was 6 months for 50% and more than 17 months for 10%. This study shows that the antileukemic drugs can prolong the survival time in the majority of children with leukemia. An important fact to be taken into consideration is that prolonging the life of an individual child may give him the opportunity to benefit from a new and perhaps more effective drug.

Periarteritis Nodosa: Report of Three Cases Successfully Treated by Cortisone and A. C. T. H. I. Z. Yonis. Ann. paediat. 192:65-80 (Feb.) 1959 (In English) [Basel, Switzerland].

The author cites previous reports indicating that periarteritis nodosa is recognized during life in a relatively small percentage of patients, and that the number of patients who recover either spontaneously or after treatment is limited. In recent reports on successful treatment, recovery was said to depend on whether the treatment had been started before vital organs were affected. This report is concerned with 3 children in whom periarteritis nodosa was diagnosed and successfully treated. There were 2 boys and 1 girl, ranging in age from 6 to 9 years. All had pain in the abdomen and in the lower extremities, cachexia, brownish-gray or bluish-gray color of the skin, profuse sweating, tachycardia, septic fever, leukocytosis, increased sedimentation rate, absence of reaction to antibiotics, appearance of nodules in the skin (in the first patient 66 days, in the second 16, and in the third 11 days after admission). Two patients had melena; one had characteristic roentgenologic findings in the ureters. The migrating pain, the septic fever, the nodules in the skin, and the roentgenologic findings in the ureters were of particular diagnostic importance. The diagnosis of periarteritis nodosa was corroborated in all 3 children by biopsy of subcutaneous nodules. Such nodules are transitory, and, as observed in the cases presented, they may disappear after a few days or even after a few hours. Therefore, one must look for them repeatedly. The biopsy of nodules offers the best chance of a positive histological diagnosis. In patients in whom periarteritis nodosa is suspected, histological examination should be repeated several times before a negative biopsy report is accepted as definite.

Steroid treatment should be started in every case suspected of periarteritis nodosa even before the clinical diagnosis is confirmed by histological examination. The influence of treatment with cortisone or corticotropin (ACTH) is manifested by a fall in the temperature within the first 24 to 36 hours. If no immediate change occurs, another steroid or ACTH should be given. Fall in temperature, improvement in the patient's general condition, and a more active attitude serve as indications of a favorable reaction to steroids. The sedimentation rate does not reflect the clinical course. The dosage of cortisone or ACTH must be individualized; treatment must be given up to the tolerance limit of the patient and continued without interruption until its discontinuance is not followed by exacerbation. Of the patients presented, one responded to treatment with cortisone. The condition of the second patient deteriorated during the administration of cortisone but improved after treatment with ACTH. The third patient improved after receiving ACTH only.

Absence of Intestinal Viral Flora in Infants During Epidemic of Escherichia coli Gastroenteritis. V. M. Young, J. Warren and R. B. Lindberg. Proc. Soc. Exper. Biol. & Med. 100:579-581 (March) 1959 [Utica, N. Y.].

The authors point out that many instances have been recorded in which specific strains of Escherichia coli have been isolated from most, or all, cases in outbreaks of infant diarrhea. Several investigators suggested the possibility that such diarrheas are the result of interaction between the pathogenic bacterium and a virus. The studies described in this paper investigated this possibility. Numerous Esch. coli 0-111:B_4 organisms were present in fecal samples obtained from all but 2 of 25 patients and were also isolated from one specimen of vomitus in an outbreak of diarrhea in infants. No Salmonella or Shigella organisms or pathogenic protozoa were found. Treated stool samples collected from 25 infants were inoculated into monkey-kidney and HeLa-cell tissue cultures, embryonated eggs, and a variety of young animals by various routes. No viral agent could be detected. It is concluded that this outbreak of gastroenteritis was caused by Esch. coli 0-111:B_4, uncomplicated by other microbial agents.

Exchange Transfusions by Catheterization of the Abdominal Aorta in Newborn Infants. E. Saling. Geburtsh. u. Frauenh. 19:230-235 (March) 1959 (In German) [Stuttgart, Germany].

The author performed successfully 3 exchange transfusions in newborn infants by introducing immediately after birth 2 catheters into the abdominal aorta of the infants. With the umbilical cord still pulsating, one catheter was introduced through an incision about 3 cm. above the umbilical ring into one of the umbilical arteries, and a second catheter was introduced into the other umbilical artery; both catheters were passed by way of the corresponding internal iliac and common iliac arteries into the abdominal aorta. Passing of the catheter through the pelvic loop in the vascular track at the transition of the umbilical cord from the anterior abdominal wall to the small pelvis was carried out without difficulty, since a flexible plastic tube of polyvinyl chloride (1.5 mm. in diameter) was used. The catheter entering the aorta distal from the heart was used for the drip infusion of the donor blood, and the catheter entering the aorta proximal to the heart was used for the withdrawal of the infant's blood. This resulted in a highly improved technique of blood exchange. The injection of the donor blood and the simultaneous withdrawal of the infant's blood were accomplished in the simplest manner. The procedure is sparing and without danger for the infant.

For infants in whom one succeeds in introducing only one catheter into the abdominal aorta or in whom the second catheter becomes obstructed, the author recommends a modified technique in which one umbilical artery and the umbilical vein are used for catheterization; the donor blood should be injected by way of the artery, and the infant's blood withdrawn with the aid of the venous catheter which has a larger diameter (2.1 mm.). Three additional exchange transfusions were performed by this technique in infants with good results. For infants in whom erythroblastosis may be recognized only after birth, an improved exchange transfusion technique is recommended in which 2 catheters are introduced into the umbilical vein.

The blood oxygen saturation was studied in the course of the exchange transfusions. The degree of oxygen saturation was gradually reduced by 20% after the institution of the transfusion in several of the infants, and that despite well-functioning respiration and satisfactory cardiac performance. The saturation values increased rapidly when oxygen was administered by means of a tracheal tube. Routine administration of oxygen seems, therefore, to be justified in the course of every exchange transfusion in infants.

Effects of Season and Temperature on Childhood Plumbism. A. M. Baetjer. Indust. Med. 28:137-143 (March) 1959 [Chicago].

A review of the literature on lead poisoning in children revealed a marked seasonal distribution with almost all the cases occuring between the months of May and October. This seasonal distribution has been attributed to various factors, such as exposure to the ultraviolet radiation from the sun in summer and the resulting increase in vitamin D which increases the absorption of lead from the intestines and the deposition of lead in the bones. The increase in environmental temperature during the summer months also has been suggested as a factor responsible for the seasonal distribution of acute lead poisoning cases in children.

A series of experiments was carried out in the laboratory of Johns Hopkins University in Baltimore to study the effects of environmental temperature and humidity on the susceptibility of mice to lead poisoning. The animals were injected either intraperitoneally or intravenously with a single dose of lead acetate or lead nitrate sufficient to cause death in about 20 to 40% of the mice at a temperature of 72 F with about 50% relative humidity. Exposure to a high temperature of 95 F increased the mortality significantly, hastened the onset of deaths and accelerated the rate of dying. Because children sweat in high temperatures and may become dehydrated, it seemed possible that the seasonal distribution of lead poisoning in children might be attributed to dehydration rather than to the high temperature. Dehydration was produced in mice by restricting water intake. Dehydration significantly increased the mortality at temperatures of 72 and 95 F and hastened the onset of deaths at the high temperature.

In additional experiments the effect of high temperature on chronic lead poisoning was studied in mice. In these experiments the mice were injected intraperitoneally 6 days per week with smaller doses of lead nitrate than those used in the acute experiments. The mortality was significantly higher and the latent time significantly shorter in the lead-injected mice exposed to a temperature of 95 F than in those kept continuously at a temperature of 72 F. The physical mechanism responsible for the higher mortality and the more rapid onset of illness and death in the animals at the higher temperature is not clear. The excretion of lead in the urine and feces of the mice was compared at 72 F and 95 F temperatures. The determinations showed that at the higher temperature the animals excreted significantly less lead in their urine over a period of 14 days after the intravenous injections of lead than did the animals kept at 72 F. The total fecal output of lead was also somewhat less at the high temperature.

Ataxia Teleangiectatica. C. E. van der Hoog. Maandschr. kindergeneesk. 27:26-33 (Jan.) 1959 (In Dutch) [Leiden, Netherlands].

The author calls attention to a report by Boder and Sedgwick (abstracted, J. A. M. A. **167**:1435 [July 12] 1958), which cited 8 children with progressive cerebellar ataxia, all of whom had telangiectasia of the bulbar conjunctiva and a butterfly-shaped area of the face. The patients also were subject to recurrent respiratory infection, which gave rise to bronchiectasis. Van der Hoog presents the case of a 15-year-old girl who had progessive cerebellar ataxia and typical telangiectasia of the bulbar conjunctiva. The patient was hospitalized 7 times for recurrent pulmonary infections. When she was 7 years old, lobectomy and lingulectomy of the left lung had been performed on account of extensive bronchiectasis, but there was no improvement; respiratory infections continued to occur. Neurological examination revealed grimacing, athetotic movements of arms and legs, a peculiar speech defect, convergent strabismus, and an ataxic walk.

The syndrome presented by this patient had a striking resemblance to that described by Boder and Sedgwick under the term "ataxia telangiectasia." The author feels that "familial" could be added to this term, since the syndrome has at times been observed in several members of a family. The recurrent infections of the respiratory tract should be treated in order to avoid bronchiectasis. These infections are about the only aspects of the syndrome that can be treated; the ataxia is progressive and eventually leads to complete invalidism. Children with this syndrome have average intelligence, although their facial expression may suggest mental deficiency.

DERMATOLOGY

The Treatment of Dermatomycoses with Orally Administered Griseofulvin. H. Blank and F. J. Roth Jr. A. M. A. Arch. Dermat. **79**:259-266 (March) 1959 [Chicago].

Griseofulvin, a colorless, neutral, thermostable antibiotic isolated from Penicillium griseofulvum, was used in treating 22 male and 9 female patients, between the ages of 5 and 71 years, with mycoses caused by various species of dermatophytes. Eighteen of the 31 patients received orally 1 Gm. of the antibiotic daily, while the other patients were given daily doses varying from 1.5 to 5 Gm. The duration of treatment varied from 10 days to 15 weeks. The organisms causing the mycoses included Trichophyton rubrum (27 patients), Candida albicans, T. mentagrophytes, T. tonsurans, Microsporum audouini, M. canis, Malassezia furfur, Epidermophyton floccosum, and Blastomyces dermatitidis.

The patients showed a uniformly favorable response to oral therapy with griseofulvin. Those with infections of long duration, up to 60 years, seemed to respond as readily as those with infections present for a few weeks or months. Infections caused by C. albicans, M. furfur, and B. dermatitidis did not seem to respond to this therapy. Tinea corporis usually cleared in 1 or 2 weeks; itching usually ceased in 3 to 5 days. Tinea pedis improved within 1 or 2 weeks but sometimes required 3 or 4 weeks or longer to clear. Tinea capitis improved within 2 or 3 weeks but occasionally required more prolonged treatment. Onychomycosis required 3 or 4 months to clear, but new normal nail growth was seen earlier. Cultures of epithelial lesions often became negative in one week. Direct potassium hydroxide preparations became negative in about 2 weeks. Infected hair and nails appeared to contain viable fungi until the involved portions were replaced by healthy new growth.

Although toxic reactions appear to be minimal with therapeutic doses in man, animal experiments indicate that repeated peripheral blood cell counts at least should be performed during a course of prolonged therapy. An urticaria-like drug eruption occurred after 6 weeks of continuous therapy in one patient, and others had mild self-limited complaints of gastrointestinal distress and headache. A daily dose of 1 Gm. of the antibiotic seems to be adequate, although the minimum effective dose and the optimum dose have not been established for all types of infection. The duration of treatment required probably will vary, apparently depending on the time required for normal replacement of the infected tissues. Likelihood of relapse or recurrence of infection is as yet not known.

Some Practical Aspects of the Diagnosis and Management of Shoe Dermatitis. A. A. Fisher. A. M. A. Arch. Dermat. 79:267-274 (March) 1959 [Chicago].

The diagnosis of shoe dermatitis depends on the history, the clinical picture, positive patch-test reactions to shoe material, and the patient's ability to wear proper substitute shoes without dermatitis. In the author's patients with shoe dermatitis, rubber —either in the rubber thermoplastic box toe or in the rubber cements—was the commonest cause of allergic contact dermatitis. This rubber sensitivity was apparently most often due to additives, such as antioxidants and accelerators. Chromates, dyes, and nickel also occasionally caused allergic contact shoe dermatitis.

The materials used by the author for a "screening" patch-testing shoe tray included thermoplastic rubber box-toe material, 1% monobenzyl ether of hydroquinone in petrolatum, 1% 2-mercaptobenzothiazole in petrolatum, 1% tetramethylthiuram monosulfide in petrolatum, 0.25% aqueous potassium dichromate, 2% paraphenylenediamine in petrolatum, and 5% aqueous nickel sulfate solution. Details are given as to how to obtain these materials and how to prepare them for patch testing. Use of such a shoe tray may facilitate the diagnosis of allergic contact dermatitis and obviate the necessity for the dissection of shoes to obtain materials for patch testing. However, negative reactions to the substances in the patch-testing tray do not necessarily exclude shoe dermatitis. It may be necessary to test with materials from the suspected shoe. The names and addresses of shoe manufacturers and retailers are given from whom shoes may be obtained which are free from certain known specific sensitizers.

Nonspecific factors also may play their part in shoe dermatitis. Perspiration can leach out chromates, rubber additives, and dyes from shoes and thus cause contact of these potential sensitizers with the skin. Ill-fitting shoes and certain foot abnormalities may cause excessive friction and wearing away of protective inner shoe linings and allow more intimate contact of shoe sensitizers with the skin. The use of a noncaking dusting powder (fluffy tannic acid, boric acid, bentonite, and purified talc dispensed in a sifter box) may occasionally prevent dermatitis by reducing perspiration. Also, orthopedic correction of various deformities or the wearing of special orthopedic shoes may be necessary to correct certain types of shoe dermatitis not necessarily of the allergic contact type.

A Contrast of Cutaneous Cancer as Observed in Texas and in Minnesota. F. W. Lynch, C. F. Lehmann and J. L. Pipkin. A. M. A. Arch. Dermat. 79:275-283 (March) 1959 [Chicago].

Comparison of 2 series of patients with cutaneous cancer from 2 practices in the northernmost (Minnesota) and southernmost (Texas) areas of the United States, in which there is great difference in temperature and total hours of clear sunlight, revealed that cancer of the skin is much more frequently observed in Texas than in Minnesota. Both the basal-cell lesions and the squamous-cell lesions occurred at earlier ages in Texans than in Minnesotans. Basal-cell lesions occurred more frequently in women. They occurred at earlier ages than did squamous-cell lesions other than those of the neck and the lower lip, which were seen almost exclusively in men and more frequently in Texans. Actinic exposures appear to explain these differences, but they do not explain completely the behavior of basal-cell epitheliomas. If basal-cell epitheliomas relate with actinic exposure, then why do they occur earlier in women than in men? Greater actinic exposure is not likely to be great enough for the complete explanation. However, difference in actinic exposure may be at least part of the explanation for greater absolute, not relative, incidence of basal-cell epitheliomas among Texans, the occurrence in that state at an earlier age, and the relatively greater incidence of such lesions on the forehead, as compared with patients in Minnesota.

Behavior of Glutamic Pyruvic Transaminase in Blood Serum and in the Serum of Blisters in Patients with Eczema and Bullous Dermatoses. G. Weber and H. Theisen. Arch. klin. u. exper. Dermat. 208:93-97 (no. 2) 1959 (In German) [Berlin].

The investigation of the behavior of glutamic pyruvic transaminase (GP-T) in patients with skin diseases seemed important after it had been demonstrated that another aminopherase, glutamic oxalacetic transaminase (GO-T), exhibited a much greater activity in the intraepidermal space of the cantharides blister and of the spontaneous blister than in the blood serum of the same patient. The authors compared the GP-T activity in the serums of blood and of skin blisters in 20 patients with skin lesions of the eczema-dermatitis group (weeping eczema, eczema rhagadiforme, intertriginous eczema, lichenoid eczema, dermatitis, and diffuse neurodermatitis), and in 9 patients with bullous dermatoses (erythema exudativum multiforme, pemphigus vulgaris, bullous serum exanthem, bullous photodermatoses, and dyshidrosis). In preliminary studies on persons without skin or metabolic disorders, the authors had found that the activity of GP-T in 1 ml. of blood serum was in the range of 5 to 35 units. These values corresponded to those obtained by Wroblewski of New York.

The values obtained in the 2 groups of patients are tabulated. In the patients with lesions of the eczema-dermatitis group, the activity of the GP-T was within the normal range in the blood serum as well as in the blister fluid. The only exception was a diabetic patient with intertriginous eczema, in whom the activity was much higher in the blisters than in the blood serum. The values in the blisters and in the blood serum in the individual patients showed no great differences, and the differences that existed showed no regularity or any relationship to the existing skin lesion. The same lack of relationship between GP-T activity and skin process was evident in the group of patients with bullous dermatoses. Thus, the results of these studies speak against, rather than for, the development of this aminopherase in the human skin.

The Hypereosinophilic Syndrome with Specific Cutaneous Changes (Eosinophilic Leukemoid). L. Pfleger and J. Tappeiner. Arch. klin. u. exper. Dermat. 208:98-115 (no. 2) 1959 (In German) [Berlin].

Cutaneous eosinophilic granulomas have been observed in many dermatoses. Eosinophilia of the tissues, "histoeosinophilia," is widely regarded as the manifestation of an allergic phenomenon, but it is still a question whether the histoeosinophilia of disorders designated by some investigators as "symptomatic eosinophilia" and by others as "cutaneous eosinophilic pseudogranulomas" is likewise an allergic reaction elicited by local tissue breakdown. The allergic origin of the eosinophilia of the blood and bone marrow has been experimentally demonstrated. It is generally accepted as a manifestation of a hypersensitivity reaction in serum disease, anaphylaxis, bronchial asthma, allergic rhinitis, allergic enteritis, angioneurotic edema, urticaria, purpura, helminthiasis, drug intoxications, and so on. Even the so-called familial eosinophilias are related to allergic diseases. Symptomatic eosinophilias differ from another group of allergic diseases, in which the blood picture is leukemoid.

The authors describe the symptom complex of eosinophilic leukemoid on the basis of the history of a woman (born in 1913), in whom an eosinophilia ranging from 13 to 70% had been demonstrated repeatedly between 1948 and 1958. The leukocyte count ranged at times up to 23,000 per cubic millimeter, and this was accompanied by generalized swelling of the lymph nodes and peculiar cutaneous lesions. The skin lesions began when the patient was 24 years old, and took the form of itching papular eruptions on the extremities, which became intensified by exposure to dusts (threshing) and by certain foods. At the age of 39 (in 1952) the woman for the first time showed erythematous swelling of the orbital, palpebral, and perioral regions with inflammatory infiltration at the angle of the mouth and with generalization of the papular exanthem. Various diagnoses were considered. The severe and persisting blood eosinophilia in the presence of leukocytosis and skin lesions even suggested a myeloid, eosinophilic leukemia, but this was rejected because of the long duration of the disease and on the basis of the myelogram.

Eosinophilic leukemoid was considered because the woman had the following signs characteristic of this disorder: persisting eosinophilia in the presence of leukocytosis; generalized swelling of lymph nodes; enlargement of liver and spleen; long duration of the disease with survival; and histological findings in lymph nodes and liver. The cutaneous changes had not been described in earlier reports on this syndrome. The histological aspects of the skin lesions, however, particularly the inflammatory reticulogranulomatous proliferation and the excessive number of eosinophils, corresponded to the allergic-hyperergic reaction of the tissues. In this woman not only the shock organs of first rank (bone marrow, blood, and liver) but also those of second rank (skin) were involved.

Various factors, such as helminths, bacteria, pollen, and foods, may play a part in the etiology of eosinophilic leukemoid, which is known also as the hypereosinophilia syndrome, but its pathogenesis is uniform in that it represents an allergic reaction in an hyperergic organism which, as a result of constitutional factors, is predisposed to hypereosinophilia. The lack of the histaminopexic capacity of the serum, demonstrated by Parrot's histaminopexic test, provided additional proof of the existence of an allergic reaction in a sensitized organism.

UROLOGY

Mortality Following Prostatectomy. P. G. Fox, Jr. and A. I. Dodson, Sr. North Carolina M. J. 20:67-69 (Feb.) 1959 [Winston-Salem].

A total of 362 prostatectomies were performed at the Medical College of Virginia in Richmond during the years from 1941 through 1946 (1945 excluded). Of those procedures, 291 were transurethral resections, while 71 were open procedures through either the suprapubic or the perineal approach. Thirteen deaths followed the transurethral resections, while 7 deaths followed the open procedures. From 1952 through 1956, 983 prostatectomies were performed, of which 798 were transurethral resections and 185 were open procedures by the suprapubic, retropubic, and perineal approaches. Seven deaths followed the transurethral resections, while 6 deaths followed open operations. The mortality following transurethral resections in the earlier period was 4.4%, with a decrease to 0.87% in the later period. There was also a similar drop in mortality after open prostatectomy from 9.9 to 3.2%, making an over-all decrease from 5.5 to 1.3%.

Comparing these figures with those reported in the literature, the authors found that there were 160 deaths among 7,910 patients undergoing transurethral resections during 1940-1945. Mortality varied among reports from 0.8 to 14%. One thousand two open-prostatectomy procedures, with 67 deaths, were reported during the same years. Mortality again varied greatly among reporting authors, ranging from 1 to 16.7%. During the years from 1950 through 1955, 5,715 transurethral resections were reported, with 81 deaths; and 2,123 open-prostatectomy procedures, with 38 deaths. The average mortality following transurethral resection was 2.1% in the earlier period, with a decrease to 1.4% in the later period. A similar drop in mortality was noted following open prostatectomy, from 6.7 to 1.8%. The authors feel that the slight difference in mortality after transurethral resection and after open prostatectomy during the recent period is probably due to the fact that more transurethral resections are carried out on poor-risk patients.

The over-all decrease in mortality from prostatectomy has been from 2.6 to 1.5%. An analysis of the causes of death after prostatectomy revealed that cardiopulmonary complications ranked first in both periods. It is suggested that electrocardiographic studies be added to the other routine examinations in evaluating the patient preparatory to prostatectomy. This will at least make it possible to identify the patients most likely to have cardiovascular complications and to plan the treatment accordingly. Only by careful preoperative evaluation and postoperative care will it be possible to reduce the mortality from prostatectomy in the future.

Combination of a New Synthetic Estrogen with Cytostatic Action and Prednisone in the Treatment of Prostatic Cancer. A. Toffol and L. Cattani. Arch. ital. urol. 31:439-458 (Jan. 20) 1959 (In Italian) [Bologna, Italy].

Seven patients with prostatic cancer received one or more courses of an Italian preparation of hexestrol diphosphate (Citostasina) combined with prednisone and supplemented by the administration of corticotropin (ACTH). A course of treatment consisted of a daily dose of 500 mg. of Citostasina administered intravenously twice a day for a week; half of this dose was subsequently administered for from 2 to 5 weeks. Prednisone was given orally in gradually diminishing daily doses, consisting of 15 mg. for each of the first 3 days, of 10 mg. for each of the succeeding 20 days, and of 5 mg. a day for the remaining period. ACTH was administered in doses of 10 units once every 5 days during this treatment.

This chemotherapeutic treatment proved to have an effective, but limited, cytostatic action. It was well tolerated, it produced almost no side-effects, and it had no feminization effects. The general state of health improved in all patients, pain decreased or disappeared, and the disturbances of urination, where present, subsided. The extent of the tumors and of metastatic lesions remained unchanged on roentgenologic or rectal examination. The authors believe that this combined chemotherapeutic management in patients with prostatic cancer, but without metastatic lesions, can complement the surgical therapy. It still seems to be the best choice even in those instances in which metastases are present, because it provides pharmacological adrenalectomy and orchiectomy by sole medical means.

OPHTHALMOLOGY

On Non-Penetrating Corneal Transplantation. G. de Ocampo and R. B. Espiritu. J. Philippine M. A. 35:1-10 (Jan.) 1959 [Manila].

Although many penetrating keratoplasties have been performed in the Philippines during the last 9 years, nonpenetrating or lamellar keratoplasty has been done rarely. In fact, lamellar keratoplasty is the least known of the developments in corneal transplantation. Central penetrating keratoplasty is not the ideal method for many of the Philippine patients requiring keratoplasty because of the extent, nature, and position of the leukoma or the vascularization, unevenness, thinning, or thickening of some areas. Some opacities do not involve the posterior layers of the cornea, and in these cases, if the vision is 20/100, 20/200, or slightly poorer, the risk of penetrating keratoplasty worsening the preoperative vision is disturbing to the surgeon, especially so if the other eye is completely blind. In these instances nonpenetrating is preferable to perforating keratoplasty.

Although many corneal surgeons consider nonpenetrating lamellar keratoplasty technically more difficult, the authors found that the corneal dissector recently designed by one of them (de Ocampo) greatly lessened the technical difficulties of lamellar keratoplasty and keratectomy. The de Ocampo dissector is designed to split stromal lamellae at their cleavage planes and also to cut the many minute interconnections between lamellae of different layers. With this dissector it is sufficient to cut only about one-fourth or less of the circumference of the cornea to dissect the whole corneal lamella up to and even beyond the limbus. The authors report observations on a series of 49 patients, whom they recently subjected to lamellar keratoplasties with the aid of the new corneal dissector at the Philippine General Hospital and at the de Ocampo Eye Hospital, in Manila. The series included patients with superficial corneal opacities, ocular pemphigus, extensive or recurrent pterygium, extensive leukomas, corneal ulcer, and corneal burn. Mechanical and biological problems of lamellar corneal grafting are discussed. Different methods are briefly reviewed, and the new technique is described. Representative cases are shown in illustrations. While the problems of infection, inflammation, and clouding, also viability of the donor cornea and diseases of the host, are the same with nonpenetrating as with penetrating keratoplasty, the nonpenetrating method, nevertheless, has several advantages. Since the endothelium and Descemet's membrane of the host are not replaced, the graft has better chances of nourishment, is less liable to be complicated by glaucoma and vascularization, and involves practically no danger of new anterior synechiae. The authors emphasize the expanding usefulness of lamellar keratoplasty.

Exophthalmos of Exophthalmic Goiter: ACTH and Cortisone Treatment. P. de Paula e Silva and W. da Silva Prado. Rev. paulista med. 54:101-106 (Feb.) 1959 (In Portuguese) [São Paulo, Brazil].

Two men, 54 and 30 years old, were hospitalized for treatment of exophthalmos of toxic goiter, which had lasted for 2½ years. The patients lost weight (20 and 12 kg. [44 and 27 lb.], respectively) during the last few months. The goiter was small and diffuse. Exophthalmos was marked, and the symptoms of hyperthyroidism were severe. The patients complained of extreme fatigability, various ocular symptoms of exophthalmos, pain in the eyes, and visual disorders. The treatment consisted of corticotropin (ACTH) and cortisone. ACTH was given intravenously in daily dosage of 40 units for 32 days to one patient and 35 days to the other. Cortisone was given by mouth in daily dosage of 200 mg. for 32 and 105 days respectively. The hormonal treatment caused a marked lowering of hyperthyroidism, diminution of the size of the goiter, disappearance of ocular symptoms and of ocular pain, and improvement of vision. The satisfactory results remained unchanged for 3 months, when a subtotal thyroidectomy was performed. The first patient was discharged after the operation in satisfactory condition with good immediate and late results. In the second patient the immediate results of subtotal thyroidectomy were excellent. However, on the 4th day after the operation the patient exhibited an attack of psychosis with mental depression, hemiparalysis on the right, and coma. He did not react to prednisone administered orally and to the intravenous administration of dextrose and died on the 6th day after the operation. Apparently the attack was due to the prolonged administration of cortisone. Autopsy revealed only moderate edema of the left cerebral hemisphere.

According to the authors, exophthalmos of toxic goiter is due to hypersecretion of thyrotropic hormones, which results from an imbalance of thyrotropic and corticosuprarenal hormones at the level of the thalamus-hypophysial system. ACTH and cortisone normalize the hormonal imbalance and also the secretion of thyrotropic hormone and prepare the patients, for a certain time, for a favorable general and metabolic state for a subtotal thyroidectomy followed by good results.

Incontinentia Pigmenti Associated with Changes in the Posterior Chamber of the Eye. J. G. Cole and H. G. Cole. Am. J. Ophth. 47:321-328 (March) 1959 [Chicago].

The authors were consulted about a 4½-month-old boy because of bilateral ocular abnormalities which on examination proved to involve a mass in the posterior chamber. Because of a striking skin condition, a dermatologist was consulted, and on the basis of clinical examination and histological study, a diagnosis of incontinentia pigmenti was made. Because the growth in the left eye strongly suggested glioma, the eye was enucleated. The greater part of the iris angle was obliterated by adhesion of the iris over most of the limbus, but the marginal sinus was clearly identified and included cysts in some areas. The iris was atrophied and distorted, and the pigment lay several millimeters over the posterior surface. On one side a newly formed membrane extended from the iris to the cornea. The ciliary body and ciliary processes were deformed by traction on the posterior surface of the lens. A membrane had formed on the ciliary body due to chronic cellular exudate and fibrin deposition. The choroid and sclera were not altered except in the area near the nerve where there was considerable inflammatory reaction extending through the cribriform plate into the vaginal sheath. The retina was completely detached and incorporated into a membrane that extended across the retrolental space and also extended posteriorly to the optic nerve, which it tended to pull forward. The normal cellular structure of the retina was hidden in the massive fibrous detachment by a cyst which separated its layers on one side. Both the cyst and the space back of the retina were filled with clear, pink-staining fluid containing some debris.

Seven cases of typical incontinentia pigmenti were collected from the literature, in all of which the diagnosis was confirmed by histological study of the skin lesion. The findings in these 8 patients showed that the syndrome of incontinentia pigmenti usually includes associated congenital defects besides those of the skin. In about one-third of the cases the dysplasia is manifested in one eye, sometimes in both eyes, but rarely to the same degree in both eyes. The mass in the posterior chamber associated with incontinentia pigmenti seems difficult to distinguish from retrolental fibroplasia. It is, however, a congenital lesion, occurs usually in infants born at term, and is most frequently unilateral. The masses in the posterior chamber of the eye in patients with incontinentia pigmenti are clinically more variable than those of retrolental fibroplasia and are also more likely to be associated with other congenital defects of the eye. The more severe cases of mass in the posterior chamber can usually be differentiated from neoplasm by the presence of other congenital anomalies or defects in metabolism, and occasionally by the presence of similar defects in the family, suggesting a genetic factor. As far as is known, provisional diagnosis of neoplasm has not been established in any of these cases.

Ocular Sarcoidosis. D. G. James. Am. J. Med. 26:331-339 (March) 1959 [New York].

Ophthalmic involvement was observed in 50 (25%) of 200 patients with clinical or radiologic features of sarcoidosis supported by histological evidence of sarcoid tissue. The ocular manifestations included those of subacute iridocyclitis in 11 patients or chronic iridocyclitis in 19 patients, phlyctenular or nonspecific conjunctivitis in 8 patients, keratoconjunctivitis sicca in 7 patients, follicular collections in the conjunctival fold of the lower eyelid in 3 patients, retinal periphlebitis in 1, and cataracts in 1. Patients with subacute iridocyclitis had a sudden onset, clinical evidence of inflammation, and occasional complete clearing within 6 months, whereas chronic iridocyclitis developed insidiously and persisted because of complicating ocular fibrosis. Subacute iridocyclitis was accompanied by transient skin lesions in contrast to chronic iridocyclitis which was accompanied by indolent skin lesions. These striking differences may have been in part due to corticosteroid therapy which was practiced within days, or at most weeks, of the onset of symptoms in most of the patients with subacute iridocyclitis, whereas patients with chronic iridocyclitis had waited several years for the introduction of corticosteroid therapy which has probably changed the natural history of sarcoid iridocyclitis. Ocular sarcoidosis was commonly accompanied by intrathoracic and cutaneous lesions of sarcoidosis and by lymphadenopathy. Reduced secretions due to simultaneous involvement of lacrimal and parotid glands superficially resembled Sjögren's syndrome in 2 patients.

Comparison of the 50 patients who had ocular lesions with the 150 patients who did not have ophthalmic involvement revealed that the patients with ocular sarcoidosis belonged to an older age group in which the peak occurred in the 4th or 5th decade with a mean age at onset of 39 years; women predominated, and the patients' reactions to Mantoux tests were more often negative. Histological evidence of sarcoid tissue was obtained by biopsy of various tissues and also by means of Kveim's skin test which gave positive results in most of the patients with ocular sarcoidosis. Blind conjunctival biopsy was of no diagnostic help. The natural course of sarcoidosis is toward spontaneous healing by fibrosis. In the eye this may cause serious complications, and, therefore, ocular involvement is an absolute indication for early and energetic corticosteroid therapy.

THERAPEUTICS

Anticoagulant Therapy: Clinical Experience With Acenocoumarin (Sintrom) and Other Coumarin Derivatives. Y. Desrochers, N. Aérichidé and P. David. Am. Heart. J. 57:321-326 (March) 1959 [St. Louis].

Anticoagulant therapy with coumarin derivatives has been employed in 382 patients, 305 of whom received acenocoumarol (Sintrom), 40 received bishydroxycoumarin (Dicumarol), and 37 received ethyl biscoumacetate (Tromexan). Experience with these anticoagulants during 4 years of study has included a total of 650 patient-months of therapy, of which 604 patient-months represent treatment with acenocoumarol. Of the 382 patients, 287 demonstrated coronary artery disease, and 95 presented other cardiovascular diseases. The Quick prothrombin time test was used in all cases to measure the adequacy of therapeutic control.

Of the 3 coumarin derivatives studied, acenocoumarol proved to be far more potent than either bishydroxycoumarin or ethyl biscoumacetate for anticoagulant therapy, particularly in patients with coronary artery disease who require maintenance for long periods of time. The optimum loading dose of acenocoumarol employed in the 305 patients was 11 to 25 mg. over a period of 18 to 60 hours. The condition of the patients was thereafter maintained satisfactorily on an average dose of 3.6 mg. daily. It has been observed that a much lower dose of acenocoumarol is required for induction when the prothrombin time is prolonged to begin with. Induction can be accomplished most satisfactorily in such patients with half the usual loading dose. Patients with renal or cardiac insufficiency also require smaller doses of acenocoumarol. Induction of therapy in 43 of the 305 patients with right heart failure was accomplished, on the average, with 16 mg. of acenocoumarol over 48 hours; the maintenance dose thereafter was 3.1 mg. Patients with uremia required no reduction of the loading dose, but their condition was maintained satisfactorily on doses averaging 2.7 mg. The therapeutic levels of hypoprothrombinemia in the 40 patients receiving bishydroxycoumarin could be established after 3 to 6 days with a loading dose averaging 445 mg. during the first 48 hours, followed by a maintenance dose averaging 79 mg. daily. Equivalent results were obtained in the 37 patients receiving ethyl biscoumacetate with a loading dose of 1,280 mg. during the first 24 hours and a daily maintenance dose averaging 387 mg.

While the effect of bishydroxycoumarin is sufficiently stable to be useful, its delayed action necessitates that heparin be used initially, and the persistence of hypoprothrombinemia after withdrawal increases the danger of hemorrhagic complications. Ethyl biscoumacetate, whose action is rapid and more easily subject to control, has produced in a number of patients marked fluctuations in prothrombin levels. The action of acenocoumarol, on the other hand, is intermediate in onset and duration, and prothrombin time is easily maintained within a therapeutic range. Hemorrhagic and thromboembolic accidents were infrequent in the patients of this series, and it appears that the mortality of patients with coronary artery disease is markedly reduced by anticoagulant therapy.

Restoration of Sinus Rhythm in Experimental and Clinical Ventricular Arrhythmias by Methoxamine Hydrochloride. I. C. Brill, J. D. Krueger and E. L. McCawley. Am. J. Cardiol. 3:307-313 (March) 1959 [New York].

Methoxamine (Vasoxyl) hydrochloride was given to dogs in which ventricular arrhythmias had been produced by various experimental procedures; these included the ligation of the left anterior descending coronary artery; the production of myocardial necrosis by injecting, through the intact chest, a suspension of zinc hydroxide into the left ventricular wall; and the intravenous administration of an overdose of digoxin and acetyl strophanthidin. Bigeminal rhythms were produced in the dogs by a new experimental procedure consisting of continuous intravenous infusion of amodiaquin (Camoquin) hydrochloride. Methoxamine administered in doses of 0.5 to 1 mg. per kilogram of body weight suppressed the various ventricular arrhythmias in the dogs for periods of 30 to 60 minutes.

Methoxamine then was given a therapeutic trial in 14 hospitalized patients with ventricular arrhythmias. The drug was administered intravenously by diluting the contents of an ampul, 20 mg., in 250 cc. of 5% dextrose. In a few instances the drug was given by intermittent intramuscular injection. Of the 14 patients, 11 had ventricular arrhythmias associated with myocardial infarcts; 1 with diffuse coronary sclerosis had ventricular arrhythmia believed to be the result of digitalis intoxication; and 2 had ventricular arrhythmias, either irregular or coupled, occurring without any apparent cause. The maximum dose of methoxamine given to the 11 patients was 20 mg. administered over a period of 20 minutes. The patient with digitalis intoxication was given a total dose of 10 mg. Of the 2 patients with arrhythmia of unknown causation, one with multifocal ventricular arrhythmia received a total dose of 5 mg. of the drug, and the other with persistent quadrigeminal rhythm received a total dose of 25 mg. As in the experimental animals, methoxamine in single doses was capable of suppressing clinical ventricular arrhythmias in most of the patients for periods of 20 to 40 minutes. After myocardial infarction the drug was as effective in patients with normal blood pressure as in those with hypotension or in shock.

The Insulin Equivalence of Salicylate. J. Reid and T. D. Lightbody. Brit. M. J. 1:897-900 (April 4) 1959 [London].

The authors studied the insulin equivalence of aspirin in 9 women and 5 men, between the ages of 33 and 74 years, with diabetes mellitus, whose insulin requirements as outpatients ranged from 14 to 112 units per day. The amount of insulin which could be replaced by a maximal tolerated course of aspirin was determined in each patient. Aspirin therapy was started and insulin therapy continued. Aspirin was administered in doses varying between 0.7 and 1.5 Gm. given 5 times daily to attain maximum therapeutic serum salicylate levels of 35 to 45 mg. per 100 cc. and to give the drug every opportunity to exert a full therapeutic effect under well-controlled conditions. Estimations of the fasting blood sugar level and urinary sugar were continued, and insulin administration was reduced progressively if warranted by the biochemical findings. Nine patients whose condition was well controlled with insulin had good responses to aspirin. The largest quantity of insulin zinc suspension replaced completely with aspirin was 48 units; the largest reduction in insulin requirement was 72 units in the patient receiving 112 units daily. The condition of 5 patients, which was poorly controlled with insulin, was not materially improved with aspirin therapy. It was concluded that aspirin was most effective in patients who responded well to insulin, and vice versa. The findings in patients whose condition was well stabilized with insulin also suggested that, the higher the insulin requirement, the greater was the amount of hormone that might be replaced by aspirin.

Transient but serious symptoms of anorexia and nausea developed in 7 patients and went on to vomiting in 1 patient. These symptoms were controlled by reducing aspirin dosage and lowering the serum salicylate level. The "special salicylate syndrome" of mental confusion, dehydration, and hyperventilation associated with a respiratory alkalosis was observed in mild form in one patient; signs and symptoms disappeared when aspirin was withdrawn. During salicylate therapy 12 of the 14 patients noticed varying degrees of impaired hearing, which reverted to normal after administration of the drug was discontinued. Tinnitus occurred in 7 patients but tended to disappear spontaneously as time went on. The reported data place salicylate in the class of promising orally administered antidiabetic substances; they should stimulate investigations to remove the undesirable effects of the drug and to find out its mechanism of action.

Combined Treatment with Emetine and Chloroquine of Amebic Hepatitis: Elective Indications and Advantages. V. Scaffidi and R. Astuto. Minerva med. 50:317-324 (Feb. 7) 1959 (In Italian) [Turin, Italy].

The authors report on the effect of emetine combined with chloroquine in 6 male patients with amebic hepatitis. The first patient, who was 58 years of age, was observed on the 9th day after the onset of a markedly progressive hepatitis, which discouraged the administration of adequate quantities of emetine because of marked toxic infectious symptoms and hypotension which also caused gastric intolerance to chloroquine. One cycle of treatment with low doses of both drugs had a good rapid effect: a remission of the symptoms followed soon; aspiration puncture of the liver was not necessary; erythrocyte sedimentation rate became normal in a short period of time; the patient recovered, and no further treatment was necessary. The second patient, who was 70 years of age, had been suffering from hepatitis for 3 months; his general condition was poor; he had fever, anemia, hypotension, and tachycardia. Complete recovery was obtained after 11 days of treatment with total doses of 0.44 Gm. of emetine and 6 Gm. of chloroquine; the latter drug was given for 8 days only. The erythrocyte sedimentation rate dropped before completion of the treatment. The remaining 4 patients, 44, 51, 60, and 36 years of age, respectively, were treated with emetine given in a similar dose as in the 2 previous cases; chloroquine was given in a dose of 1 Gm. per day. Three of these patients improved rapidly and recovered completely after only one cycle of treatment. The 4th patient recovered more slowly; no relapse of hepatitis was observed a few months later when the patient suffered from an episode of persistent ulcerative colitis, which was cured with emetine combined with Aureomycin. The emetine-chloroquine treatment had no untoward side-effects.

The Use of Chlorothiazide in the Nephrotic Syndrome. G. E. Burch and H. A. White Jr. A. M. A. Arch. Int. Med. 103:369-380 (March) 1959 [Chicago].

Chlorothiazide is a new diuretic agent which is useful in the treatment of many clinical disorders, including congestive heart failure, cirrhosis, nephrosis, essential hypertension, premenstrual edema, and toxemia of pregnancy. Among its various clinical advantages are (1) remarkable effectiveness when administered orally and (2) prompt diuretic action, consisting of water diuresis, natruresis, and chloruresis but only minimal kaluresis. Chlorothiazid is twice as potent as acetazolamide. The authors studied 10 patients with the nephrotic syndrome associated with various types of renal disease; these patients received oral treatment with chlorothiazide at the Charity Hospital of Louisiana in New Orleans between 1955 and 1957. The diet of all patients contained a constant known intake of electrolytes (1.5 Gm. of sodium) and of protein (78 Gm.).

Chlorothiazide proved to be an effective, and sometimes dramatic, diuretic agent. Six of the 10 patients had the classical picture of the nephrotic syndrome with edema and were refractory to conventional therapy. The response to chlorothiazide in these patients was striking. One of these patients, a 16-year-old girl with proliferative and membranous glomerulonephritis, generalized edema, and ascites, failed to respond to conventional therapy. The patient was then given 0.5 Gm. of chlorothiazide twice daily, resulting in a loss of weight of 24 lb. (11 kg.) within 9 days and a considerable improvement of well-being. She was discharged edema-free, on a maintenance dose of 250 mg. of chlorothiazide daily. When seen 3 months later, she had no edema or evidence of electrolytic imbalance, although the condition of the urine and hypoproteinemia were unchanged. In another patient who had severe diabetic glomerulosclerosis, the diuretic response to the first course of chlorothiazide was better than the response to a single injection of a mercurial diuretic. The diuresis was accompanied by a pronounced increase in urinary excretion of sodium and chloride but a minimal increase in excretion of potassium.

In 9 patients studied before and during chlorothiazide therapy, the mean daily excretion of sodium increased from 122 to 200 mEq. per liter, of chloride from 118 to 188 mEq., and of potassium from 45 to 58 mEq. The rates of plasma clearance for sodium, chloride, and potassium were higher in all the patients during administration of chlorothiazide than were the control values, with occasional exceptions when a mercurial diuretic was used. The total quantity of sodium excreted during therapy with chlorothiazide far exceeded that of potassium. The creatinine clearances of all the patients remained essentially unchanged throughout the entire study, indicating no significant change in glomerular filtration. Although the urinary volumes in these patients increased at the time of administration of chlorothiazide, they lost relatively greater quantities of electrolytes than of water, and the specific gravity of their urine was 1.012 or greater.

Although renal biopsies have not been repeated, no evidence was found that chlorothiazide had any detrimental effect on the basic renal lesion. This drug appeared only to promote diuresis and to produce dry weight. This, in turn, had considerable psychological and clinical benefit for the patients who had been edematous for long periods of time despite other intensive therapy. All edema was eliminated in these patients by oral treatment with chlorothiazide, except for facial edema associated with steroid therapy in 2 patients.

Developments in Fibrinolytic Therapy for Thrombo-Embolic Disease. S. Sherry, A. P. Fletcher and N. Alkjaersig. Ann. Int. Med. 50:560-570 (March) 1959 [Lancaster, Pa.].

Considerable progress has been made in developing systemic fibrinolytic therapy for use in man. The naturally occurring precursor of the fibrinolytic enzyme of serum is referred to as plasminogen or profibrinolysin. In the presence of a kinase or activator, this normal serum globulin is converted to plasmin or fibrinolysin. Streptokinase, a hemolytic streptococcic product, is the best-known of the activators and has been used in most laboratories. Plasmin, also to be referred to as fibrinolysin, is a proteolytic enzyme. Although plasmin digests fibrin into several soluble polypeptides, this proteolytic enzyme is capable of digesting such additional plasma constituents as fibrinogen, accelerator globulin, and some of the components of serum complement. Free plasmin in blood is rapidly inhibited by antiplasmins found in serum and platelets. Plasminogen is closely related to fibrinogen and fibrin. Plasminogen and fibrinogen appear simultaneously in areas of exudation, and significant amounts of plasminogen are adsorbed onto fibrin during clotting. This close relationship is probably of physiological significance.

In discussing the mechanism by which a thrombus is lysed, the authors point out that the level of activator in the circulation, rather than the level of circulating fibrinolysin, becomes the critical factor in controlling the rate of lysis of a thrombus. The importance of plasminogen in the circulation is not to induce fibrinolysis but to endow thrombi or fibrinous exudate with sufficient plasminogen to mediate its lysis.

To test this hypothesis, a study was conducted on patients subjected to procedures known to enhance the fibrinolytic activity of the blood. It was possible to demonstrate that, after electroshock, pyrogen therapy, ischemia, exercise, and epinephrine injections, the enhanced fibrinolytic activity was associated with the release of activator in, or into, the circulation; yet there were no significant changes in the plasmin or the fibrinogen concentrations of the plasma. Four methods of fibrinolytic therapy were considered: (1) the use of pharmacological agents capable of influencing the release of the physiological activator; (2) the use of purified preparations of known activators; (3) the use of purified preparations of human plasmin; and (4) the use of other proteolytic enzymes capable of hydrolyzing fibrin, e. g., trypsin and chymotrypsin.

Direct control of the circulating activator level may be accomplished by prolonged infusions of large amounts of highly purified activator preparations. Although urokinase, an activator derived from human urine, probably would be most desirable for this purpose, it is not yet available in pure form, and a highly purified streptokinase has been used. Therapy has been instituted by the intravenous injection of a priming dose of streptokinase, dependent in amount upon the level of circulating antibody and varying between 10,000 and 200,000 units. Thereafter, the level of circulating activator has been maintained by a sustaining infusion of 30,000 to 100,000 units of streptokinase an hour. This regimen, based on studies with isotopically labeled streptokinase, maintains a plasma level of from 3 to 10 streptokinase units per milliliter.

The more than 50 patients treated by this technique included some with acute coronary thrombosis and myocardial infarction, deep vein thrombophlebitis with and without complicating pulmonary emboli, thrombotic occlusions of large arteries, and arterial and venous occlusions of retinal vessels. Evidence has been obtained in some instances that intravascular fibrinolysis has been produced. Other activators, e. g., urokinase, may prove to be less antigenic and more useful than streptokinase, or perhaps pharmacological methods for controlling the natural activator level may be developed.

Clinical Evaluation of Formamidinyliminourea, a New Biguanide Oral Blood Sugar Lowering Compound: Comparison with Other Hypoglycemic Agents. L. P. Krall and R. F. Bradley. Ann. Int. Med. 50:586-613 (March) 1959 [Lancaster, Pa.].

The search for orally effective hypoglycemic agents preceded the advent of insulin; it began in 1914 when it was discovered that hypoglycemia was accompanied by increased levels of guanidine in the blood and that the administration of guanidine produced hypoglycemia. Further study of guanidine derivatives led to the finding of a higher homologue, Synthalin, a decamethylene-diguanidine, which produced hypoglycemia in normal and in diabetic dogs after parenteral or oral administration. Synthalin decreased glycosuria in human diabetics, and clinical success in some mild and moderately severe diabetic patients was reported. While Synthalin was being used by many investigators, insulin was assuming its physiologically sound position in diabetic treatment. The authors discuss the metabolic effects and the action mechanism of Synthalin and compare it with a new series of orally administered hypoglycemic agents known as biguanides or formamidinyliminoureas.

The present report evaluates the clinical characteristics of 4 biguanide analogues. These are DBI, the phenethylformamidinyliminourea, and the closely related derivatives: DBB, the normal amyl; DBTU, the isoamyl; and DBC, the methylbenzyl analogue. Certain parallels and differences between these compounds in terms of chemistry, metabolic effects, side-effects, and possible sites of action are noted. The toxicity reported with guanidine and Synthalin has not occurred to date in experimental or clinical observations with the biguanides. Effects of biguanides used for varying periods of time up to 17 months were evaluated in 173 patients with all types of diabetes, including 53 juvenile-onset cases. Duration of diabetes was from newly diagnosed to 35 years. Of the study group, 150 patients (88%) showed demonstrably lowered blood sugar levels, while 66 (38%) were unable to continue biguanide therapy because of gastrointestinal side-effects in the doses used. Although gastrointestinal side-effects occurred frequently, they were rapidly reversible. No clinical toxicity was noted. Hepatic, renal, and hemotological studies have revealed no abnormality to date. The long-term effects of the biguanides are still to be determined. Comparison with other hypoglycemic agents suggests that, when used with certain precautions, they have clinical value in selected cooperative patients.

The Artificial Kidney. F. M. Parsons and B. H. McCracken. Brit. M. J. 1:740-751 (March 21) 1959 [London].

The authors report on 100 patients who were referred to the artificial kidney unit of the General Infirmary at Leeds, England. Of the 100 patients, 63 had acute reversible renal failure which occurred as a complication of pregnancy in 25, as a result of or associated with trauma in 25, and from other causes in 13; 13 patients had acute irreversible renal failure; 13 patients had postrenal obstruction which was reversible in 9 and irreversible in 4; and 11 patients had miscellaneous condtions, 9 of whom had an exacerbation of chronic renal disease. Eighty-two of the 100 patients underwent hemodialysis with an improved Kolff-Brigham rotating type of artificial kidney. Of the 63 patients with acute reversible renal failure, 45 were dialyzed. There were 24 female and 21 male patients, between the ages of 13 and 67 years. The basic treatment was a dietary regimen consisting of 400 cc. of water and 100 Gm. of dextrose daily, with vitamins. The most consistent indication for dialysis was clinical deterioration, particularly early mental changes, nausea, and vomiting. The biochemical indications were a blood urea nitrogen level of 180 to 200 mg. per 100 cc., a potassium level of 7 mEq. per 1,000 cc., and a carbon dioxide combining power of 13 mEq. per 1,000 cc.

The metabolic response, estimated by the daily rise of the blood urea nitrogen level, was remarkably constant in any one patient, and a classification of the illness into mild (rise less than 15 mg. per 100 cc. a day), moderate (rise of 15 to 30 mg. per 100 cc. a day), and severe (rise of 30 mg. or more per 100 cc. a day) is suggested. The patients with mild illness were frequently managed successfully without dialysis, while those with moderate illness (mainly those with complications of late pregnancy) usually required a dialysis between the 6th and the 10th day. The patients with severe illness (mainly those with renal failure associated with trauma, accidental or surgical) often required dialysis as early as the 4th or 5th day. In the patients with severe illness the incidence of complications, particularly sepsis, was high and the mortality greater. Many of these patients were referred to the artificial kidney unit too late; earlier transfer might improve the prognosis.

The metabolic response in women with acute reversible renal failure occurring as a complication of pregnancy was reduced by 70% when the patients were given 30 mg. of norethandrolone (Nilevar) daily. Administration of this steroid might largely eliminate the need for dialysis in pregnant women. A similar action has not been observed in other conditions. Of 9 patients with reversible postrenal obstruction and uremia who were dialyzed, 7 had prostatic obstruction with retention of urine. After dialysis all were improved clinically. In 3 of the 7 patients, prostatectomy was performed 7 days or less after the dialysis, but in the other 4 prostatectomy had to be delayed until renal function had improved, and in 1 of these 2 further dialyses were required. The number of patients with chronic renal failure referred to the artificial kidney unit was too small for justifiable conclusions to be drawn. In those patients with acute renal failure of not clearly understood origin, dialysis was used so as to maintain life while diagnostic procedures were undertaken. If an irreversible condition was found, no further dialyses were performed.

Streptomycin Poisoning in Renal Failure: An Indication for Treatment With an Artificial Kidney. K. D. G. Edwards and H. M. Whyte. Brit. M. J. 1:752-754 (March 21) 1959 [London].

Three men, between the ages of 28 and 68 years, and 2 56-year-old women who had been treated with a total dose of streptomycin varying from 4 to 14 Gm. for recurrent pyelonephritis or for postoperative prophylaxis after an orthopedic operation and a thoracotomy, respectively, were observed at the Sydney (Australia) Hospital in the past 2 years. All had permanent vestibular damage and evidence of renal disease. In 2 patients with acute oliguric renal failure, the symptoms of vestibular damage appeared 24 days after the administration of the last dose of streptomycin and after diuresis had occurred. A simple, semiquantitative, in vitro test showed that streptomycin can be removed from the blood by dialysis. These observations induced the authors to give hemodialysis a trial in 3 women and 2 men, between the ages of 30 and 62 years, with acute renal failure who had received 1.5 to 10 Gm. of streptomycin for prophylaxis after surgical intervention and for septicemia respectively. Hemodialysis was performed as early as possible, within 3 to 9 days after the institution of streptomycin therapy. Signs of toxicity did not occur in any of these patients. Accumulating experience emphasizes the importance of estimating renal function before giving a course of streptomycin. There is every reason to believe that early removal of streptomycin, which is confined to the extracellular fluid in the body, by dialysis should assist in preventing vestibular damage. Administration of streptomycin in patients with renal failure is to be considered one of the few conditions calling for immediate treatment with an artificial kidney.

PHYSIOLOGY

Agammaglobulinemia and Alymphocytosis with Atrophy of the Lymphatic Tissue. W. H. Hitzig, Z. Biro, H. Bosch and H. J. Huser. Helvet. paediat. acta 13:551-585 (Dec.) 1958 (In German) [Basel, Switzerland].

The distinction between cellular and humoral defense mechanisms has become better understood since discovery of patients with agammaglobulinemia made possible a better evaluation of humoral factors. The authors present the histories of 2 male infants who had an especially low resistance to infection. This was the result of a double defect, namely, an absence of humoral antibodies (agammaglobulinemia) and of cellular elements (alymphocytosis). The clinical course was, therefore, extremely unfavorable and proved more resistant to therapy than is usually the case in agammaglobulinemia. The insufficiency of the 2 important defense mechanisms revealed the following characteristics in the 2 infants: 1. Onset was toward the end of the first 3 months of life. 2. Severe diarrhea which proved resistant to all therapy resulted in severe cachexia. 3. There was persistent lowering of the lymphocyte count, although the total number of leukocytes and of neutrophils varied. (4) Gamma globulin values in the blood were extremely low, and specific antibodies and isoagglutinins were absent. 5. Allergic reactions were the same as in normal persons. One patient died of a hemolytic–uremic syndrome with all the characteristic features of the generalized Sanarelli-Shwartzman phenomenon. The other patient had a severe neurological disorder (hemiplegia). Autopsy studies on both infants revealed that the entire lymphatic system was atrophic.

The authors feel that the cases presented are important for evaluation of the relations between cellular and humoral defense mechanisms. Contradictory opinions have been expressed about the site of origin of the humoral antibodies. According to the lymphocytic theory it is deduced from antibody determinations in lymph and in lymphocytes that the latter contain and transport antibodies. However, histological studies on stimulated lymph nodes indicate a secretion of antibodies by sessile elements, that is, by activated reticulum and plasma cells. Two refined modern techniques permit corroboration of the plasma-cell theory. The gamma globulins can be demonstrated in plasma cells with the aid of fluorescent anti-gamma-globulin serums and with the electron microscope. It can be demonstrated that plasma cells have an ergastoplasm, that is, a highly organized system of intracellular concentric membranes and granules; lymphocytes and the plasma cells of the peripheral blood do not have them. It can also be demonstrated how the plasma cell achieves contact with the corresponding antigen. Plasmatic protrusions of macrophages that contain the antigen reach into kidney-shaped invaginations of the plasma cells; at the sites of contact the membrane becomes very thin, so that the organelles of the plasma cell are enabled to "palpate" the surface of the antigen. A plasma-cell theory of the formation of antibodies is formulated on the basis of these observations.

Electrocardiograms of Weight-Lifters: Study of Findings of 26 Subjects. R. Etzenhouser, M. Dunn and E. G. Dimond. J. Kansas M. Soc. 60:121-125 (March) 1959 [Topeka].

The weight-lifter is an example of a highly conditioned athlete in whom the demands on the cardiovascular system are just the opposite of the usual requirements of physical fitness. Practically all other physical fitness sports require sustained demands on cardiac output by increasing stroke volume and heart rate. The weight-lifter does immense physical work while performing a Valsalva maneuver. The weight-lifter impedes venous return, decreases cardiac filling, and decreases cardiac output at the same moment he exerts maximal effort. The authors made electrocardiographic studies on 26 male weight-lifters, ranging from 16 to 40 years of age. These men had been weight lifting from 4 months to 10 years for 1½ to 20 hours per week. Preliminary examination consisted of obtaining a medical history, weight-lifting history, blood pressure, and auscultation of the heart. A standard 12-lead electrocardiogram was then taken on each subject, who next completed 50 trips over the standard Master 2 steps in 3 minutes. Immediately after exercise, leads I, II, III, V_4, V_5, and V_6 were taken and repeated at 2-, 4-, and 6-minute intervals thereafter.

Three of the 26 subjects had abnormal exercise electrocardiograms. An arrhythmia developed after exercise in one man; another one before exercise had T-wave inversion which reverted to normal immediately after exercise; and in a third man there developed a terminal depression of the S-T segment with inversion of the T waves. Only the changes developing in the last of these 3 men could be interpreted as possibly demonstrating myocardial ischemia. The T-wave inversion noted in the one man at rest is of the innocent variety, since it has been produced in young adults by many factors, including emotional stress, autonomic dysfunction, and a full stomach. The authors conclude that the electrocardiographic changes were probably physiological adaptations well within the capacities of the normal heart.

BOOK REVIEWS

Treatment of Cancer and Allied Diseases. Volume II: Tumors of the Nervous System. By thirty authors. Edited by George T. Pack, M.D., F.A.C.S., Attending Surgeon, Memorial Center for Cancer and Allied Diseases, New York, and Irving M. Ariel, M.D., F.A.C.S., Associate Clinical Professor of Surgery and Associate Attending Surgeon, New York Medical College, Flower and Fifth Avenue Hospitals, New York. Second edition. Cloth. $15. Pp. 316, with 340 illustrations. Paul B. Hoeber, Inc. (medical book department of Harper & Brothers), 49 E. 33rd St., New York 16, 1959.

The first edition of this book appeared in 1940. The present edition contains much useful information, and the authors selected to prepare the various sections are among the most outstanding authorities in the United States. Unfortunately outdated material has not been entirely eliminated, and the book has not been completely modernized. Few if any neurological surgeons would today use the surgical approach for an acoustic neuroma illustrated in figure 1-15, page 12, or in figure 11-5, page 164. Figure 1-17, page 13, gives a most inadequate idea of the procedure of cerebral lobectomy. Not many surgeons would curve the incision for a subtemporal decompression forward, as shown in figure 1-20, page 16. In discussing the prognosis of the treatment of the benign astrocytomas of the cerebellum it should be pointed out that most of these patients can be permanently cured if they are properly treated. There are numerous other points to which one might take exception. In too many instances one finds the subject matter superficially dealt with, particularly the subject of prognosis. On the other hand, chapter 3 on anesthesia, chapter 4 on preoperative and postoperative care, and chapters 18 and 19 on tumors of the peripheral and sympathetic nervous systems are well written. Chapter 10 on the treatment of intracranial meningiomas is one of the best in the book. While the bibliography is poorly arranged, the index is adequate.

History of the Second World War: United Kingdom Medical Series. Editor-in-chief: Sir Arthur S. MacNalty, K.C.B., M.A., M.D. The Army Medical Services: Campaigns. Volume III: Sicily, Italy, Greece (1944-45). By F. A. E. Crew, F.R.S. Cloth. 100 shillings. Pp. 645, with 136 illustrations. Her Majesty's Stationery Office, Atlantic House, Holborn Viaduct, London, E. C. 1, England, 1959.

This third volume of the history of the medical service of the British Army in World War II deals with both the preparations for and the actual invasion of Sicily, Italy, and Greece. Although military strength and effectiveness in these campaigns were more gravely threatened by disease than by enemy action, a high standard of health promotion, disease prevention, and individual treatment was reached. In Italy malaria, venereal disease, dysentery, typhoid, and typhus were all prevalent. These hazards were aggravated by the fact that the troops were often exposed to rain, snow, and wide variations in external temperature. Furthermore they moved amid a teeming civilian population whose social and economic life had been disrupted by the war. Long periods away from home had a deteriorating effect on the morale of the troops, thereby decreasing their attention to personal hygiene and increasing their susceptibility to disease.

Although this volume is generally well written, it contains a superabundance of tactical details which are not of general interest. The appendixes, 26 in all, are scattered throughout the book at the end of individual chapters rather than being all placed at the end of the book. In the front there is an extensive list of abbreviations without which the book would be unintelligible. Even so, there are a few omissions, probably of those abbreviations already familiar to most British readers. There are many photographs, but most of the illustrations are simple maps. There is an index. Those in the United States who have a special interest in military medicine should find it interesting to compare the British procedures and conclusions with those of our own forces regarding the campaigns in these countries.

Neoplastic Disease at Various Sites. Volume II: Tumours of the Bladder. Edited by David M. Wallace, O.B.E., M.S., F.R.C.S. General editor: D. W. Smithers, M.D., F.R.C.P., F.F.R. Cloth. $11.50. Pp. 352, with 202 illustrations. Williams & Wilkins Company, 428 E. Preston St., Baltimore 2; E. & S. Livingstone, Ltd., 16 and 17 Teviot Place, Edinburgh 1, Scotland, 1959.

This is one of many monographs on neoplastic diseases published under the general editorship of Dr. Smithers. There are 14 contributors. As monographs go, this volume is exceedingly large, but it is by far the best publication on bladder tumors available. The publishers have done an excellent job in that the paper is of high quality, the print is easy to read, and the illustrations, charts, graphs, photographs, photomicrographs, and colored plates are excellent.

The contributors have presented their various topics in a clear, concise, and informative style. The book is "all meat." Each chapter is well arranged, and many have conclusions (all have references at the end). Too much has been written about cancer without a clear definition of what is to be discussed. The industrial risk in the development of certain bladder tumors has been recognized for some years. Although formerly described as aniline dye cancers, it is now recognized that these neoplasms can be

---

These book reviews have been prepared by competent authorities but do not represent the opinions of any medical or other organization unless specifically so stated.

produced by many chemicals similar in every respect to those that appear spontaneously. In spite of all modern advances in treatment the mortality from bladder cancer is rising. These facts and many others, including etiology and biochemistry, are presented in the first three sections.

There is a large section on the pathological behavior and the mode and method of spread of bladder cancer. There is also an analysis of postmortem findings and manner of death. The last three sections contain discussions of the classifications, methods of treatment, analysis and result of treatment, and an appraisal of the various methods. The observations on treatment as presented confirm those of Jewett, in that once the bladder musculature has been penetrated the chances of cure diminish rapidly. The book has an excellent appendix which includes many interesting charts and statistics. The whole subject of bladder tumors, including classification and treatment, is controversial. There are those who will take exception to some of the opinions expressed in a few of the chapters. A few may even believe that some of the subject matter has been treated too superficially. Be this as it may, the monograph can be highly recommended not only to the urologist but to the radiotherapist, industrial chemist, investigator, and anyone else enterested in cancer.

Chirurgie der Arterien. Von Doz. Dr. K. Kremer. Mit einem Vorwort von Prof. Dr. Ernst Derra. Cloth. 59 marks; $14.05. Pp. 280, with 150 illustrations. Georg Thieme Verlag, Herdweg 63, (14a) Stuttgart, West Germany; [Intercontinental Medical Book Corporation, 381 Fourth Ave., New York 16], 1959.

This is a purely technical treatise on the surgery of blood vessels, including a short history of vascular operations and a description of instruments; homograft, heterograft, and plastic transplants; and the treatment of various forms of visceral and peripheral arterial syndromes. There is a short chapter on diagnostic methods. Photographs are well reproduced, but many of the diagrams are too small and too sketchy. The material is well organized and the bibliography is extensive. For the German-speaking surgeon, the book offers a good summary of present concepts. One may note with pride that most of the recent developments in this field come from English or American sources. There is little to recommend it for the reader in this hemisphere.

Surgical Treatment of Mitral Stenosis. By Helge Baden. [Thesis, M.D. University of Copenhagen.] Translated from Danish by Axel Andersen. Paper. 20 Danish kroner. Pp. 263, with 17 illustrations. Store Nordiske Videnskabsboghandel, Copenhagen, Denmark, 1958.

This monograph analyzes a series of 165 patients treated by mitral commissurotomy and compares it with other series reported in the literature. The monograph begins with a comprehensive but concise review of the literature. The symptoms, clinical findings, and laboratory findings are discussed in detail, with tables and graphs to illustrate important factors. Operative technique is described, with details of the findings at operation and the complications that arose. The operative mortality of 10% is analyzed and details of postoperative complications are given. Comparison of the diagnostic and operative findings is made with special reference to the degree of stenosis and the amount of regurgitation. Postoperative results are reported objectively with 52% of the patients improved, 26% unchanged, 6% worse, and 16% dead. Factors influencing these results are analyzed. A comprehensive bibliography is included.

Radiation Biology and Cancer: A Collection of Papers Presented at the Twelfth Annual Symposium on Fundamental Cancer Research, 1958. Published for University of Texas M. D. Anderson Hospital and Tumor Institute. Cloth. $8.50. Pp. 493, with illustrations. University of Texas Press, Austin 12, 1959.

This book contains a series of papers reporting studies on the physical and chemical aspects of radiation and radiobiology encountered in investigations of the cause and treatment of malignant disease. Observations of a preliminary nature which call attention to the basic factors involved in these problems are presented. The book should serve as a reference point for critical students in the fields of radiation and cancer, but it may not find general acceptance by the average reader, since the material is highly specialized. The fact that the book reveals important vistas of this complex subject may result in a future stream of publications on many of the challenging aspects of the problem.

Bronchography. By C. Dijkstra, M.D., Medical Superintendent of "De Klokkenberg," sanatorium and chest hospital, Breda, Netherlands. Translated from Dutch manuscript by Th. R. Heemskerk. Cloth. Hfl. 19.50. Pp. 157, with 106 illustrations. Koninklijke van Gorcum & Co. N.V., Assen, Netherlands; Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill., 1959.

Reading the title of this book, published so many years after the development of this diagnostic method, one wonders what it can add to what is common knowledge. This question the author has carefully considered and well answered in his preface. Inasmuch as this procedure is increasingly recognized as a necessary part of a complete study of the lungs, and inasmuch as it is being used more and more by those who have not had extensive experience with it, a monograph of this type, which describes the technique of injecting the oil and the interpretation of the bronchograms, is definitely needed. There is much in the book that should add to the knowledge even of those who have wide experience with bronchography. It should, therefore, be of great value to the less experienced. The text is brief but well written and adequate. The illustrations are numerous and excellent, and the author's method of using case histories to present the diagnostic pictures is well adapted to this subject.

Praktische Anatomie: Ein Lehr- und Hilfsbuch der anatomischen Grundlagen ärztlichen Handelns. Erster Band/dritter Teil: Arm. Von Dr. T. von Lenz, o. ö. Professor der Anatomie, Direktor des Anatomischen Institutes der Universität München, und Dr. W. Wachsmuth, o. ö. Professor der Chirurgie, Direktor der Chirurgischen Universitätsklinik und Poliklinik, Würzburg. Second edition. Cloth. 168 marks. Subscription price 134.40 marks. Pp. 308, with 249 illustrations. Springer-Verlag, Heidelberger Platz 3, (1) Berlin-Wilmersdorf (West-Berlin); Neuenheimer Landstrasse 24, Heidelberg; Göttingen, Germany, 1959.

This monograph on the upper extremity is part of a series of comprehensive works designed to present the anatomic basis of medical practice to the physician. In 1935 the first edition on the upper extremity appeared, followed in 1939 by a volume on the leg. The first postwar production by the anatomist von Lanz and the surgeon Wachsmuth was the volume on the neck, published in 1955. The present work is a thoroughly revised edition of the initial publication in the series. Monographs on the practical anatomy of the head, thorax, back, abdomen, and pelvis will complete the series. The volume on the arm has been reissued prior to the completion of the other proposed volumes, partly because of the intense interest in the reconstructive surgery of the hand. Destruction of the plates, drawings, and most of the printed stocks in World War II necessitated the preparation of what is in reality an entirely new edition.

As in other works in the series the anatomy of the upper extremity is presented chiefly from the regional, topographical, and functional points of view. Systematic presentation is used to a lesser degree to supplement the more practical regional approach. The aim throughout is to set forth the anatomy of the living as the foundation of medical practice in general and of surgery in particular. The illustrations, mostly in color, are large and their abundance permits the careful study of a part or an area without the confusion of a multitude of leaders and labels, as is often the situation when illustrations are few in number. Numerous "phantom" drawings are used to illustrate surface projections and relations. Neurovascular variations and their relations to muscular and bony structures are also discussed and illustrated.

A general section on the upper extremity as a whole precedes detailed accounts of the several subregions. About 70 pages are devoted to the hand. In each subsection surface anatomy, illustrations of successively deeper dissections, cross-sections, movements, joints and ligaments, muscular and bony relations, variations and anomalies, and practical applications are presented. A comprehensive list of references and a detailed index are provided. The new anatomic nomenclature (*Nomina Anatomica Parisiensia*, 1955) has been incorporated into the text. There are no illustrations of the radiologic appearance of the anatomy of the upper extremity. The type face is large, clear, and easy to read. The cover and binding appear to be sturdy and durable. It is difficult to compare this work with any other since it is unique in its comprehensiveness, and in the abundance, clarity, and general excellence of its illustrations. Although it is written in German, this fact only slightly diminishes its usefulness to a nonreader of the language. This book can be recommended without reservation to the general physician, but more specifically to the surgeon. Medical and anatomic libraries should find this an excellent addition to their reference collections.

Recent Trends in Chronic Bronchitis. Edited by Neville C. Oswald, T.D., M.D., F.R.C.P. Cloth. $7.50. Pp. 199, with 174 illustrations. [Oxford University Press, 114 Fifth Ave., New York 11]; Essential Books, Fair Lawn, N. J.; Lloyd-Luke (Medical Books) Ltd., 49 Newman St., London, W. 1, England, 1958.

The editor states that the main purpose of this book is to bring together under one cover for the first time recent views on the various facets of chronic bronchitis. Much of the text consists of the original work of several contributors. From their experience with chronic bronchitis at Brompton Hospital since 1950 the authors present their views on the diagnosis, prevention, and treatment of this distressing and often killing disease. The book begins with a discussion of the mortality and morbidity of chronic bronchitis and proceeds to the clinical pattern of the disease, which is discussed at some length. There is an excellent chapter on pathology, giving a historical review and following it with a discussion of the normal anatomy of the bronchial tree, before going into the pathological findings of the disease throughout its course. There are some excellent colored pictures of pathological slides as well as many pertinent illustrations in black and white. Other chapters discuss the radiologic appearance of the chest, the bacteriology of the disease, the effect of air pollution, the disturbances of respiratory function and of the heart in chronic bronchitis, and emphysema. The clinical management and the aspects of bronchitis in general practice are dealt with in the last chapters. References are given at the end of each chapter and there is a good index.

Each chapter is well written. This book is not meant to be an exhaustive treatise but rather a summary of the experiences and the conclusions of the group studying chronic bronchitis at Brompton Hospital. In this respect it fulfills its purpose, and it should be enjoyed by many students and general practitioners of medicine.

QUESTIONS AND ANSWERS

RECURRENT FURUNCULOSIS

To the Editor:—*A 33-year-old man started to have boils about four months ago, all of them below the level of the waistline. They have been painful and resistant to antibiotic treatment. Most of them need to be incised. All the conventional treatments have failed. A culture revealed Staphylococcus aureus. Please give advice on treatment.*

Juan Ferrando, M.D., Lima, Peru.

Answer.—The management of recurrent furunculosis should be directed not only to cure the local lesions but also to prevent recurrences by attention to the source of the infection and to the mode of transfer. The furuncles themselves require proper surgical drainage, compresses, and proper dressings. Careful cultural studies should be made to determine the exact strain of the offending organism and its drug sensitivity. Combined treatment should then be directed toward complete eradication of the lesions at all points by systemic use of the indicated antibiotic as well as by frequent skin cleansing with soap and water or with a detergent such as hexachlorophene, which leaves a thin skin film to suppress bacterial growth. Sources of chronic infection about the perineum and anus are likely to promote recurrent furunculosis, and these should be eradicated surgically or medically. The hands and undergarments should be scrupulously cleaned at frequent intervals. The anatomic distribution suggests a chronic source of infection about the perineum or anus, and particular attention must be given to the underclothing and to the hands.

CALORIE EXPENDITURE

To the Editor:—*How many calories are expended by a person weighing 150 lb. (68 kg.) walking one mile at the rate of 3 mph?* *M.D., New York.*

Answer.—According to studies reported by the Army Medical Nutrition Laboratory, the calorie cost of a man weighing 70 kg. walking on the level at a rate of 3½ mph is 5.25 per minute. Assuming the energy expenditure to be approximately the same at a rate of 3 mph, walking one mile would expend 105 calories. Further details regarding other factors that may be concerned can be obtained from the "Medical Nutrition Laboratory Report No. 177" (Denver, Fitzsimons Army Hospital, March 19, 1956). Lusk's book "Elements of the Science of Nutrition" (ed. 4, Philadelphia, W. B. Saunders Company, 1928) states that the extra energy required for walking 2.8 mph for one hour is 159 calories above the resting dietary requirement. This is equal to 17.1 Gm. of fat. The resting calorie requirement is about 40 calories per square meter per hour, and a 150-lb. man would have approximately 1.65 square meters of surface area, requiring 66 calories per hour or a total energy production of 225 calories per hour while walking 2.8 mph. This would give 75 calories as the energy expenditure for walking one mile. The more recent data are probably more representative of current techniques, which are more refined than those used when the early data given by Lusk were obtained.

TUBERCULOUS TONSILLITIS

To the Editor:—*In a patient with tuberculous tonsillitis, should tonsillectomy be performed? A 28-year-old man developed a sore throat in December, 1958. Three weeks later he noted a lump in the right side of his neck. On physical examination his right tonsil was three times as large as the left and dark red and there was a lump in the upper portion of the right side of the neck. His temperature was 38 C (100.4 F). He was hospitalized, and the lump grew larger, with a chain of tender nodes extending to the supraclavicular region. The leukocyte count was 4,000 per cubic millimeter. His fever persisted in spite of tetracycline, sulfonamides, and penicillin therapy. A biopsy specimen of the right tonsil revealed a tuberculous lesion. The patient is ambulant.*

V. A. Mandrussow, M.D., San Francisco.

Answer.—The inquirer seeks help for the treatment of an acute case of tuberculous tonsillitis, but his description of the case casts some doubt on this diagnosis. The marked enlargement of the right tonsil and its association with chain-like nodes extending to the supraclavicular region is more suggestive of malignant lymphoma, possibly of the Hodgkin's type. A blood dyscrasia must be considered in view of the low leukocyte count, and a differential count is indicated. A review of the original biopsy specimen is also in order. If this is indeterminate, excision biopsy of the tonsil and one of the cervical nodes is recommended.

Acute tuberculous tonsillitis is rare and seen only in association with pulmonary tuberculosis. It is accompanied by exudation and ulceration, and the

---

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any medical or other organization unless specifically so stated in the reply. Anonymous communications cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

patient is usually very ill. The possibility of latent tuberculosis of the tonsil associated with cervical adenopathy must undoubtedly be considered. This was formerly attributed to the bovine type of tuberculosis and has almost disappeared in recent years. The cervical node biopsy should be helpful in this determination. The mere finding of a tuberculous lesion of the tonsil on histological examination is of no great significance. Routine studies of excised tonsils may occasionally reveal this in the absence of clinical evidence of the disease. Other granulomatous diseases may produce lesions resembling tuberculosis. Tonsillectomy in this case can be recommended for diagnostic rather than therapeutic reasons.

"BODY WISDOM" DEFECT

To the Editor:—*It is understandable that one perspires when shock is due to toxemia or poisoning, but what happens to the "wisdom of the body" when the shock is due to hemorrhage or coronary thrombosis?* *M.D., New York.*

Answer.—Sweating is produced by stimulation of the cholinergic fibers present in sympathetic nerves. In shock due to hemorrhage or acute coronary occlusion, there is stimulation of the vegetative nervous system. Some of the manifestations reflect the effects of adrenergic stimulation, while other effects are typical of a cholinergic response. It is doubtful whether many of the physiological adjustments to shock are sufficiently well understood for their significance to be appreciated. Presumably, the loss of fluid by perspiration would be undesirable, but some other cholinergic effects may be essential to maintaining vital functions of the circulation. There are numerous instances in which the body does not manifest "wisdom." For example, nontoxic substances may be metabolized into toxic substances. Phagocytic cells may help disseminate infections, such as tuberculosis.

HOT WEATHER FATIGUE

To the Editor:—*What is the cause of fatigue—not discomfort—during hot weather in the summer? Is it metabolic in origin?* *M.D., New York.*

Answer.—Several factors may contribute to a sense of fatigue during the hot summer weather. These may include a general relaxation of musculature and vasodilatation, as well as electrolyte loss through perspiration. The increased vasodilation required for heat dissipation in hot weather may tend to reduce blood flow through the muscles and viscera. The altered distribution of blood flow could be a factor in producing fatigue. It is not clear to what extent the weather may influence endocrine function, but there is some reason to believe that a cold environment may tend to stimulate adrenal cortical function. Metabolism tends to be at a minimum as the environmental temperature approaches that of the body. It is hard to distinguish between physiological and psychological factors that may enter into such a complaint. There is no evidence that this form of fatigue is metabolic in origin in healthy subjects.

TREATMENT OF RESPIRATORY INFECTION AND FEVER IN A CHILD

To the Editor:—*What is the present opinion regarding treatment for a child 10 years of age with fever and a sore throat or, shall we say, any upper respiratory infection with fever in a child? Years ago early treatment was advocated as a means of aborting the illness and preventing septic complications. Recently one hears more and more of the value of letting the child handle the infection without benefit of antibiotics in order to develop antibodies. What is considered good practice today? A good deal is heard about abuse of antibiotics. When should one prescribe penicillin or a tetracycline? When are the sulfonamides indicated vis-a-vis antibiotics?*

M.D., Pennsylvania.

Answer.—Opinion as to the best treatment of fever and infection of the upper part of the respiratory tract in a child of 10 years of age may well vary, depending on the physician queried. It also will vary according to the type of infecting organism and the severity of the illness. In general, it is a satisfactory practice to treat symptomatically for three days a child who has an infection of the respiratory tract. If at the end of that time improvement is taking place, the use of antibiotic agents is not indicated. If, however, there is no improvement or if matters become worse, antibiotic treatment should be instituted promptly. If the onset of the illness is severe, antibiotic treatment ought to be started at once. Knowledge of the clinical course of the same type of infection in other children in the community also is helpful in deciding the necessity for the use of antibiotic agents. If the infecting organism is a streptococcus, it is best to start treatment without a waiting period so that any complicating illness, such as rheumatic fever or nephritis, may be prevented. Penicillin, if the patient is not allergic to it, is the drug of choice for streptococcic infections, although tetracycline hydrochloride or a sulfonamide compound may be used. The drug should be administered for at least 10 days.

The choice of an antibiotic agent depends on the infecting organism and the patient's ability to tolerate the drug prescribed. Results of culture of specimens of nasopharyngeal secretions are helpful if bacteriological facilities are available. Strains of streptococci, staphylococci, Diplococcus pneumoniae, and Hemophilus influenzae are the organisms most commonly encountered. Viral infections are not treated by the use of antibiotic agents. If any antibiotic agent is used, it should be used for at least five days and sometimes longer, during which time it is administered in full therapeutic dose.

BRONCHITIS VACCINE

To the Editor:—*How efficacious is a stock vaccine for chronic bacterial bronchitis? What about autogenous vaccine? The patient does not have tuberculosis.*

M.D., Pennsylvania.

Answer.—At the present time, the use of either stock or autogenous vaccines seems to be regarded as of questionable value in the management of chronic bronchitis. For example, the use of such vaccines is not mentioned in articles on chronic bronchitis either in the "Principles of Internal Medicine," edited by Harrison and others (ed. 2, New York, McGraw-Hill Book Company, Inc., 1954), or in the "Textbook of Medicine," edited by Cecil and Loeb (ed. 9, Philadelphia, W. B. Saunders Company, 1956). In the section on acute bronchitis in the latter book, it is stated, "The use of preventive cold vaccines has, generally speaking, proved disappointing." The treatment of chronic bronchitis has been briefly reviewed by Lloyd (*Practitioner* 175:663, 1955), who states: "Many attempts have been made to treat bronchial infections by the use of so-called respiratory disinfectants . . . and by autogenous vaccines prepared from the sputum, but the results have been disappointing."

TOLERANCE TO ESTROGENS

To the Editor:—*What conditions in the mature female allow toleration of amounts of estrogens—naturally occurring or synthetic—far in excess of what can be administered with impunity to the average patient? The condition par excellence is the state of pregnancy, but are there any others? What about tumors? Is such tolerance dependent on proper liver function?*

R. J. Kent, M.D., Savannah, N. Y.

Answer.—Nausea and vomiting occur with all estrogenic substances, natural or synthetic, but are more frequent with stilbestrol, less with ethinyl estradiol, and least with such natural substances as conjugated estrone sulfate. That the nausea and vomiting is a central effect and not due to simple gastric irritation is borne out by its occurrence with parenteral as well as oral therapy. By far the most important organ in the intermediary metabolism of estrogens is the liver, where degradation to inactive substances as well as conjugation takes place. The marked intolerance to estrogens as well as the occurrence of skin "spiders" and gynecomastia in patients with liver disease attest to this fact. The tolerance of astronomic doses of estrogen by the pregnant woman is a well-established fact; its cause is not known, but it has been postulated as due to differences in metabolism in association with high levels of endogenous estrogen. On the other hand, it has been contended that the rising estrogen titer may account for the nausea and vomiting of early pregnancy, and the lack of side-effects to administered estrogen may be simply on the basis of increased tolerance due to this rise of the endogenous levels. Certainly, patients who do not tolerate large doses may well be able to take smaller and then gradually increasing doses with impunity. It must, therefore, be concluded that the patient can develop her own tolerance to the drug. Patients with estrogen-producing tumors of the ovary should be able to tolerate estrogens in high doses, but this cannot be definitely verified. This consultant knows of no tumor which specifically increases tolerance to estrogen therapy.

PLASMACYTOSIS

To the Editor:—*What is the clinical significance of plasma cells in the blood?*

M. L. Riccitelli, M.D., New Haven, Conn.

Answer.—Plasma cells (plasmacytes) are tissue cells which are extensively distributed particularly in those organs in which reticuloendothelial cells are abundant. The lymph glands, spleen, skin, bone marrow, and intestine are the normal sites in which plasmacytes reside. Plasmacytes may pass into the circulating blood in larger numbers in pathological conditions in which the total tissue plasmacyte mass is increased (see table). Except in infancy it is unusual to observe plasmacytes in the normal state in the circulating blood. The circulation serves as the normal transport pathway for the plasmacyte as well as other leukocytes, and an occasional plasmacyte may be observed in the blood without any pathological process being evident.

Significance of Plasma Cells in Blood

1. Not generally seen in normal blood beyond 1%
2. Non-neoplastic
    - Irritation of marrow
    - Hyperimmune states
        - Antigen-antibody reactions
        - Antibiotics and chemicals
    - Inflammatory conditions
        - Subacute bacterial endocarditis, granulomas (tuberculous, syphilitic, fungal);
        - asbestosis, silicosis, pneumoconiosis;
        - rubeola, rubella, varicella, scarlatina, infectious mononucleosis, infectious hepatitis;
        - *marrow regeneration, protein deprivation, starvation*
3. Neoplastic
    - Plasma cell leukemia
    - Plasma cell myeloma
        - Neoplastic invasion of marrow
    - Other leukemias

Plasmacytes (up to 60%) may be seen in the peripheral blood during severe immunological reactions or infections, e. g., serum sickness, rubella, rubeola, scarlet fever, chickenpox, infectious mononucleosis, or infectious hepatitis. Invasion of the bone marrow by metastases, particularly of epithelial origin, results in a plasmacytosis which may give rise to a secondary diagnosis of myeloma. Circulating plasmacytes may also be found in varying numbers in multiple myeloma and plasma cell leukemia. The increase is not necessarily a constant finding but is related to the size of the tissue plasma cell pool and the rate of delivery. During chronic inflammatory conditions, such as syphilis, tuberculosis, and chronic skin infections, an occasional transitional plasmacyte (Türk cell) may be found circulating. Plasmacytes may also circulate in infantile anemia with jaundice and during return from marrow hypoplasia from either chemical or radiation hematodepression and in states in which there is general hematopoietic stimulation.

BAN ON ORANGE COLORING

To the Editor:—*What is the toxic substance or substances used in coloring oranges? What are the effects on man? Is there enough toxic material from this source in marmalade to be injurious?* *M.D., Colorado.*

Answer.—The skin of oranges has been colored with a coal-tar dye called Red 32. However, since March 1, 1959, its use has not been permitted by the Food and Drug Administration because of possible carcinogenic effects; even though the skins of oranges are not usually ingested and no toxic effects have been shown in humans, it has been shown that Red 32 applied to the skin of mice will cause a cancerous growth. It is not felt that a sufficient amount of marmalade containing orange peels colored with Red 32 would be ingested to result in harm to the average consumer. However, in view of the prohibition, it is suggested that use of oranges on which this substance is known to have been applied be limited. Of course, this will soon no longer be a problem.

TREATMENT OF WARTS

To the Editor:—*Is there any treatment, except local destruction, for ordinary multiple warts? Please mention specifically the treatment for plantar warts.*

Joseph Sharpe, M.D., Farmington, N. Mex.

Answer.—There is only one type of wart that responds to anything other than local treatment, and that is the verruca plana juvenilis. Verruca plana juvenilis sometimes responds to such medication as low dosages of mercuric succinimide. The literature is replete with recommendations for innumerable types of local treatment of plantar warts. These methods include escharotics of various types, cryrotherapy, local injections, various forms of irradiation therapy, psychotherapy, and surgical intervention, including excision and even resection of the distal metatarsal head. In data on 1,300 cases, this consultant has found that by far the lowest percentage of recurrence is in patients in whom the verruca is removed by means of electrocautery. Local anesthetic is used. The entire growth must be completely removed by curettage down to the fatty layer, leaving a margin of normal skin about the wound. When all of the verruca has been removed by curet and repeated cauterization, the remaining normal tissue, both the walls, and the base of the wound are desiccated and a dressing applied with an antiseptic ointment. The dressing is changed every several days until epithelization has taken place. If the destruction has been wide and deep, it may produce a painful site. Discomfort may be alleviated by relieving pressure on the wound. This is accomplished by cutting an opening the size of the wound in a small square of foam rubber, ¼-¾ in. thick, and applying this with adhesive over the outer surface of the dressing. The wound ordinarily heals in about 10 days to two weeks. With proper management the patient should not be incapacitated.

ENDOMETRIOSIS

To the Editor:—*Is there any scientific basis to the common saying that the woman with endometriosis should omit milk from her diet? A 43-year-old nulliparous woman with endometriosis was operated on several years ago and one ovary removed (chocolate cyst). Recently she was operated on again, and widespread endometrial tissue was found, only a fraction of which could be removed; the uterus was left intact because it was adherent to the rectum, but the second ovary was cystic and was removed. Please outline the postoperative management for hormonal (estrogen) replacement. Does it differ from that after any other oophorectomy? The menstrual history had been normal, except for dysmenorrhea.*

Calvin P. Wallis, M.D., Norman, Okla.

Answer.—This consultant knows of no basis, scientific or otherwise, for depriving women who have endometriosis of milk. This patient reported may have no symptoms of the menopause. Because of extensive earlier endometrial involvement of the ovaries, ovarian function probably was decreasing over a period of years. If this patient is disturbed by severe hot flushes or other symptoms that can be definitely attributed to the menopause, then estrogen therapy may be indicated. Small doses of stilbestrol, 0.5 mg. at bedtime, may be adequate. This is usually not enough to cause bleeding unless it is suddenly withdrawn. After the symptoms have been relieved, the dosage should be gradually decreased. If the small dosage is not adequate to relieve the symptoms, the dose of stilbestrol should be gradually increased to 100 mg. daily. This can be done by starting with 0.5-mg. tablets and increasing the dose by one tablet every third night until the equivalent of 6 mg. is taken every night. Then one-fourth of a 25-mg. tablet may be given and the dose increased one-half tablet every third day until the patient is taking 100 mg. daily. This dosage is continued for three months; then the drug is gradually withdrawn over a period of a week.

YELLOWING OF HAIR

TO THE EDITOR:—*A woman in her early 50's whose hair had previously become completely white is developing increasing yellowness of the hair. The patient uses a well-known commercial shampoo only. She has received at various times recently the following medicaments: atropine methylnitrate, 1 mg., with phenobarbital, ¼ grain (15 mg.); danthron, 75 mg. (⅓ tablet) occasionally, not daily; piperidolate hydrochloride, 50 mg.; chloroquine phosphate, 250 mg. once daily; prochlorperazine, 5 or 10 mg.; glutethimide, 0.5 Gm.; methyprylon, 200 mg.; multiple vitamins; dioctyl sodium sulfosuccinate; ethinyl estradiol, 0.05 mg. once or twice daily; and thyroid. Might any of these drugs be related to yellowing of the hair? Please suggest a remedy.*

Robert A. Straughn, M.D., Madison, Wis.

ANSWER.—A change of hair color may occur as a result of any one of several factors. In this particular instance, the only external contact involved is apparently with the shampoo mentioned and this could not produce the color change. Of the internal medicaments listed, this consultant would immediately withdraw the chloroquine, inasmuch as there have been several reports of discoloration and change in hair color after ingestion of antimalarial drugs. With this therapy discontinued, the probability exists that the hair will return to normal after an adequate period of time to permit elimination of the drug from the body. It would not be necessary to withdraw any of the other medicaments, which are presumably necessary for her medical condition, until effects of discontinuance of therapy with the antimalarial agent have been observed.

CHEST TRAUMA AND CORONARY ATTACK

TO THE EDITOR:—*Is there any causal relationship between trauma of the chest (especially over the heart area) and the precipitation of an acute coronary occlusion with infarction in a patient with existing coronary arteriosclerosis? If so, what period of time usually elapses between the trauma and the infarction?*

M.D., Florida.

ANSWER.—Trauma of the chest wall must be of considerable extent, as a rule, to cause any injury to the heart. The commonest injury, 96.8% according to Bright and Beck (*Am. Heart J.* **10**:293, 1935), is cardiac rupture. Contusion of the heart requires a degree of violence sufficient to fracture the bones and cartilages of the chest wall and to cause severe traumatic injuries to the thoracic viscera. The experience of the Medical Examiners Office in New York City, reported in the book "Legal Medicine: Pathology and Toxicology," by Gonzales and others (New York, Appleton-Century-Crofts, Inc., 1954), would indicate that a causal relationship between trauma of the chest and the precipitation of acute coronary occlusion with infarction in any patient, whether there is preexisting coronary arteriosclerosis or not, is rare. The authors know of only one such case. There was severe chest injury as well, resulting in rapid death from hemorrhage and shock. Articles in which cases are reported of presumable relationship between chest injury and coronary thrombosis are usually unsupported by careful autopsy data. Injuries of the coronary arteries due to nonpenetrating blunt force are exceedingly rare and do not occur in an isolated form. In rare cases when they do occur, there are always substantial and easily demonstrable injuries to the chest wall and contents and to other parts of the heart and great vessels.

BREAST CANCER AND ESTROGENS

TO THE EDITOR:—*A 50-year-old woman had a radical mastectomy for carcinoma of the breast seven years ago and has been symptom-free since then. Menses ceased completely about one year ago. Hot flashes are still present, and no specific treatment has been given for these. Recently, involutional vaginal changes with dyspareunia have developed. Could daily application of 2 to 4 Gm. of an estrogenic vaginal cream (containing 1.25-2.5 mg. of conjugated estrogenic substances) result in sufficient absorption to be contraindicated in view of the history of mammary cancer? If not, for what length of time may applications be continued?*

M.D., Illinois.

ANSWER.—Seven years is insufficient time to be certain that the breast malignancy has actually been cured. It is better to rely on 10 years, but this is not always a final time. Any of the estrogenic preparations, whether natural or synthetic, might have undesirable influences on any breast malignant cells still present in the body. This is a view commonly accepted today. It is one reason why some surgeons feel strongly about removal of the ovaries prior to the menopause in women with mammary malignancy. Although there is a possibility that estrogen might not have a deleterious influence, it would seem that a patient of this age should have other methods of treatment for the vaginal condition. There seems to be ample evidence that estrogens are absorbed through the vaginal mucosa. If one could be assured this patient was totally cured, estrogens could be used, but a state of doubt does exist. In this particular instance, it is best to avoid use of estrogens at this time.

Congressional Hearings on Forand Bill . .
A. M. A. Testimony . .
State Societies Review Progress . .

HEARINGS ON FORAND BILL

The House Ways and Means Committee heard more than 50 witnesses, during five days of hearings, argue for and against the controversial Forand bill to provide hospital, surgical, and nursing-home treatment to some 16 million persons through the Social Security system.

At the conclusion of the sessions, July 17, there was no indication whether the committee, headed by Rep. Wilbur Mills (D., Ark.), would take a vote on the legislation. Last year hearings also were held, but no action was taken on the measure sponsored by Rep. Aime Forand (D., R. I.), second-ranking Democrat on the committee.

The administration came out flatly against the measure. Arthur S. Flemming, Secretary of Health, Education, and Welfare, said it would be "very unwise" for Congress to approve the legislation.

Flemming asserted that the measure would establish a course from which there would be no turning back—that health coverage of the aged would "become frozen in a vast and uniform governmental system, foreclosing future opportunity for private groups, nonprofit and commercial, to demonstrate their capacity to deal with the problem."

He said that as far as possible the aged should be provided with medical care through voluntary individual and organized action. He pointed out that private health insurance has increased rapidly in recent years and predicted that 70% of the aged will have some form of health insurance by 1965.

There is no question but that the legislation "would bring to a virtual halt the voluntary efforts that are moving forward in such an encouraging manner," said the administration official. He warned that a Forand-type program would result in strong pressures to extend the benefits further, with the result that voluntary insurance "might soon be eliminated from the entire field of health protection for the aged."

Representative Forand, who questioned Flemming at length, asked why private insurance could not supplement a federal program, rather than be eliminated by it. Flemming said that the Forand program provides "reasonably adequate services" and that people would not be likely to duplicate coverage out of their own pockets.

Spokesmen for the American Medical Association and 33 state medical societies joined in urging the House committee to turn down the measure.

The American Hospital Association strongly opposed the legislation, with a spokesman contending that "the government as a purchaser of so much hospital care would exert the power of the purse in ways detrimental to the interests of hospital patients."

The AFL-CIO renewed its backing of the measure. An official of the labor organization told the committee that private insurance will never be able to handle the task of financing medical care for the elderly. Other proponents included the Physicians Forum, the National Farmers Union, the National Association of Social Workers, the American Public Welfare Association, Americans for Democratic Action, and the United Auto Workers.

Organizations that supported the stand of the administration, the A. M. A., and the AHA included the American Farm Bureau Federation, the Chamber of Commerce of the United States, the American Society of Internal Medicine, the American Dental Association, the American Pharmaceutical Association, the National Association of Manufacturers, the Life Insurance Association of America, and the Health Insurance Association of America.

Dr. R. B. Robins, a member of the A. M. A. Board of Trustees, speaking for the American Academy of General Practice opposed the measure and said it might lead to conditions such as he viewed on a recent trip to Great Britain to inspect the socialized medicine system.

A. M. A. WITNESSES

Officials of the American Medical Association and 33 state medical societies outlined to the House Ways and Means Committee the medical profession's contention that enactment of the Forand measure would stifle progress being made voluntarily, and hurt rather than help the quality of health care for the aged.

Dr. Frederick C. Swartz, Chairman of the A. M. A. Committee on Aging, and Dr. Leonard Larson, Chairman of the A. M. A. Board of Trustees, stressed the rapid progress in private health insurance and the dangers of a government health program. Representatives of the societies pointed to widespread advances in state programs.

Dr. Swartz testified that medical care is not susceptible to production-line techniques. A cooperative attack by all professions involved, including the medical profession, is needed, he said. Flexibility would vanish "the moment government established a health program from a blueprint calling for mass treatment," the witness declared.

Dr. Larson said he was proud to inform the committee that the A. M. A. is making good on the pledge that it gave the lawmakers a year ago to a dedicated continuing effort in the field of health care for the aged. "Very real progress" is being made, he said, with [illegible] villages, new nursing homes, chronic disease–care

BURROUGHS WELLCOME & CO. (U.S.A.) INC., Tuckahoe, New York

centers, home-care programs, and other projects. "And many, many more are on the way," Dr. Larson said.

Asserting that the legislation is "neither practical nor realistic" Dr. Swartz listed as some of his reasons that it would curb community incentive to support hospitals, discourage at the community level the freedom to experiment with new techniques, discourage families from taking care of their relatives, restrict beneficiaries in their choice of hospital and physician, and severely handicap the professional relationship between the doctor and his patient.

In addition, said Dr. Swartz, the program would be staggeringly expensive, costing more than 2 billion dollars a year. The measure, he contended, "simply proposes a form of national compulsory health insurance."

Summing up his statement Dr. Larson told the committee that "a compulsory system can lead only to disillusionment and to inferior medical care for those millions of older citizens who deserve the opportunity of making their extra years rewarding."

STATES REPORT PROGRESS IN AIDING ELDERLY PERSONS

Spokesmen for state medical societies presented a united front in opposition to the Forand bill. They told the Ways and Means Committee of substantial strides in their states to meet the problems of medical care for the aged. Testimony or statements were presented by representatives of 33 state societies.

"There is every reason to believe that it is still the problem of the individual, his family, the community, religious groups, and local political subdivisions, working with the various purveyors of insurance coverage to solve it—in the American way," testified Dr. Carl Fortune of Lexington, Ky., president-elect of the Kentucky Internal Medicine Society.

Dr. Daniel H. Bee of Indiana, Pa., representing the Medical Society of the State of Pennsylvania, asserted that "organized medicine and other interested groups have [worked] and will continue to work with these problems until they are solved in our state."

Another witness, Dr. Joe Johnson, speaker of the house of delegates of the Tennessee State Medical Association, said passage of the Forand bill would undermine the far-reaching and substantial progress now being attained by voluntary methods in Tennessee through health insurance.

The Texas Medical Association reported that it "is fully engaged in a multiphased program which is designed to alleviate many existing problems related to medical and surgical services for the aged." Speaking for the society was Dr. Milford O. Rouse, former president of the Texas Medical Association.

Dr. John R. Kernodle, chairman of the North Carolina Medical Society's committee on chronic illness, testified that North Carolina has pioneered in home-care and homemaker service programs for rural areas and that the voluntary approach to meeting the health problems of the aged is getting results in his state.

Dr. T. Eric Reynolds, president of the California Medical Association, said compulsory national health insurance would "destroy many helpful voluntary programs" that are proving of real benefit to California citizens aged 65 and older.

The position of the Iowa physicians was presented by Dr. Noble W. Irving of Des Moines, chairman of the state medical society's committee on legislation. "Iowa physicians have reached a degree of unanimity seldom attained in, first, proposing and carrying out a positive plan of action for improving voluntary ways and means of financing health care for our senior citizens, and, second, in opposing this proposed legislation."

"In Florida, no one who needs it goes without hospital care," said Dr. H. Phillip Hampton, chairman of the committee on legislation and public policy of the Florida Medical Association. "This includes those over 65 years of age."

Dr. George E. Twente, representing the Mississippi State Medical Association, told the committee that "our voluntary prepayment plan, the Mississippi Hospital and Medical Service, was one of the first to develop a Blue Shield-Blue Cross package contract geared to health needs of senior citizens. Growth of medical and related facilities in Mississippi since 1946 has been astonishing."

Dr. Renaio J. Azzari, member of the Board of Trustees of the Medical Society of the State of New York said, "There is no need for federal intervention, through this bill, in New York state. State and local governments have done an excellent job in providing for the aged." Of the population of the state 88 percent are now covered by some form of hospital insurance, and "it can be expected that greater advancements will take place in the future."

Dr. Vincent W. Archer of the Medical Society of Virginia testified that a special insurance policy related to the maximum income of Social Security recipients is under serious consideration in the state. "We are convinced that as programs of this nature become more widespread the competition of the marketplace for the ever-growing number of the aged can only result in better and better coverage for this group."

MISCELLANY

The Senate Finance Committee held a final one-day hearing on the Keogh measure to encourage the self-employed to invest in retirement plans. Its purpose was to allow spokesmen for organizations favoring the legislation to present their testimony, since there was not enough time at sessions earlier this year. Backing the House-passed bill at the hearing were officials of the American Optometric Association, the American Veterinary Association, the National Small Businessmen's Association, the American Retail Federation, the Chicago Bar Association, and the National Council of Salesmen's Organizations. Another day of testimony was planned later this session.

The Senate approved $88,800,000 for the Defense Department's Medicare program for the current fiscal year, the same figure cleared by the House. The Medicare program was part of an over-all 40-billion-dollar defense money measure.

The Senate completed congressional action on an administration-approved bill to extend for five years current programs of federal aid for advanced training in public health and professional nursing. Proposals by some lawmakers to broaden the program that were opposed by the administration were not included in the measure.

PRACTICAL STEPS FOR THE FAMILY PHYSICIAN IN THE PREVENTION OF EMOTIONAL DISORDER

Gerald Caplan, M.D., D.P.M., Boston

The style of work of the family physician is fundamentally different from that of the psychiatrist, but the family physician who seriously wishes to enlarge the scope of his practical operations with respect to the mental health needs of his patients does well to build up a working relationship with a psychiatrist of his choice. This can greatly improve his ability to recognize emotional needs in families, to prepare married couples for emotional problems like those of pregnancy, to help families go normally through periods of separation or bereavement, and generally to use his knowledge of the family in order to contribute to its stability. His traditional role brings him into contact with many people at times of crisis. At such times he can exert a particularly powerful effect on their mental health by steering them away from maladaptive solutions and toward adequate solutions of their life problems.

THE etiology of emotional disorder in any individual case is very complicated. Many interacting factors are involved, including those based on constitution, childhood experiences, later life problems and their solution, and details of the unfolding of the processes of growth and development in interaction with the forces of the emotional and material environment.

If one looks at this problem from an epidemiologic point of view it is still complicated, but it is simpler: by this I mean a study of the factors in one community which are responsible for its having a higher incidence of cases of emotional disorder than another community. Such studies isolate certain common factors which operate to influence all members of a community. These factors do not determine the fate in any individual case, but they lead to communitywide differences in the frequency of certain psychological illnesses.

Viewed from this standpoint it is possible to discover certain general factors which can be combated on a communitywide level. Programs to alter these factors may not affect the fate of any particular person but are likely to reduce the number of cases which occur during a subsequent period in that community.

In connection with these factors the following consideration seems important: The mental health of an individual is dependent on the continuous satisfaction of special requisites in the patterns of his psychological interaction with certain other people. We can speak loosely about a person having psychological needs which have to be satisfied in his interactions with others. The most obvious need

Based on a lecture read before the Honolulu Medical Society, August, 1957.

is the basic psychological stimulation of having people to talk to. For years we have realized that isolation has a potent harmful effect on mental health. For centuries men have tortured their fellows by marooning them on desert islands, by solitary confinement in prisons, or by ostracism in the social setting. The list of needs also includes the opportunity to give and receive love and affection, to be dependent and to be depended on, to satisfy cravings to be controlled and to control, and to be a member of a social group in which one's identity and personality are respected and accepted, so that one's achievements are rewarded by praise and one's difficulties are lightened by sympathy and understanding.

In all cultures there exist within the structure of the society small groups of people who are bound together by significant emotional ties, and within these groups the psychological needs of the individual members are satisfied. Biological ties are usually the basis of these fundamental groupings, and some form of family structure is universal. In different cultures the pattern of families varies, but, whether one studies the small family of modern Western urban culture, the large extended family of earlier Western rural culture or certain present-day Oriental cultures, or the matriarchal families of other cultures, we find that certain roles or tasks of psychological significance are allotted by tradition to each of the family members, that the sum of these tasks usually satisfies the needs of all the members, and that this sum is distributed among the members of the group so that no necessary role is left out.

In recent years we have discovered that the interactive possibilities afforded by the intact structure of the family are as necessary to mental health as the provision of adequate nutritional supplies are to physical health. When the traditional pattern of any family is altered by situational factors, the mental health of its members is endangered. This danger is greatest for the younger children, in the same way that nutritional deficiencies are most dangerous during early developmental phases, but the danger is also present for the mature adults.

Another similarity to physical nutrition is that if all goes well we do not usually realize the importance of these factors. The satisfaction of needs in an intact family takes place silently and automatically. It is only when the family structure is deficient that difficulties become obvious; since families are ubiquitous it has taken us a long time to realize the obvious fact of their importance for mental health and the close connection between defects in their structure and subsequent emotional disorders among certain of their members.

Importance of the Family Physician in Promoting Mental Health

From all this it follows that professional workers who deal with people as members of a family have a special place in programs of mental health promotion. The family physician is a worker with a uniquely important role in this regard. He is usually called in to a family to handle symptoms of physical disorder in one or more of its members. In dealing with this traditional task he may well add another dimension to his practice and focus his interest on those elements of the situation which involve dangers to the social structure of the family group, therefore involving dangers to the future mental health of its members. The concept of the family as a unit, and the physician as a worker with responsibilities to the whole unit, implies not only that he may accept as a patient any individual family member but also that when he is called in to deal with the symptoms of one member he will widen the focus of his interest to include all the others, whether from the point of view of their involvement in the etiology of his patient's condition or from the point of view of the effects of his patient on them as a group. This responsibility has been clear for years in cases of contagious disease, but we now realize that it applies equally, if not more so, to the social and psychological side-effects and sequelae of any illness. This latest insight is, as is often the case in medicine, a reformulation of old traditional knowledge; the family physicians in our parents' generation understood this quite well, although they may not have been able to spell it out as explicitly as we can nowadays. Increasing complexity in the medical sciences, increasing specialization, and increasing concentration on the exciting new discoveries in somatic medicine have to some extent pushed these old insights into the back of our minds. In the hurly-burly of busy practices, and in the absence of strong protagonists, they have fallen into disuse.

Moreover, the older training of physicians by the apprentice system allowed young men to acquire many of the skills of psychosocial management of the family by modeling themselves on the practice of experienced preceptors. The knowledge they acquired was not to be found in books but in the life situations of their apprenticeship. Nowadays the old type of apprenticeship is usually missing, and the books still say very little about all this—at least very little that is useful at a practical level—because the writers of these books have usually not carried out their studies within the framework of the actual situations of general medical practice but in the very specialized and unique conditions of psychiatric clinics and psychological laboratories.

Exhortations by psychiatrists that the family physician should play his part in promoting mental health are no great help. The family physician asks, "Exactly how should I do this?" and the psychiatrist usually has no concrete answer. In this paper I will attempt to begin to give a concrete answer—or at least to indicate specific avenues for practical exploration.

Before ending this introduction, I would like to mention one other point which supports the importance of the family physician in community programs of preventive psychiatry. He is one of the key community workers who has contact with people when they are in a state of crisis. Physical illness may be a turning point which determines a change in the whole course of a person's existence; it is important to realize that during the relatively short period of the few weeks or months of the illness all kinds of decisions may be made and all kinds of psychological reorientations, as well as alterations in the structure and functioning of families, may be worked out which will affect the type of interpersonal relationships and character of intrapersonal functioning for a long time to come.

Psychiatrists have recently joined the ranks of those who are very interested in the way people solve the emotional and social problems of periods of life crisis. Previously, it was mainly novelists and dramatists who were interested in this topic, but nowadays we psychiatrists realize that the future mental health of people may be determined at crisis times by the quality of their problem-solving methods. One type of solution of a set of problems may lead to greater mental health, which explains why many people become more mature as a result of satisfactorily overcoming life's difficulties. Another type of solution may lead to mental ill health, either immediately or in the future, and either directly for that individual or indirectly for his dependents due to damage of his emotional relationships with them.

People become emotionally disturbed during these crisis periods, but the anxiety, depression, tension, and hostility are not to be confused with symptoms of psychiatric illness, which they superficially resemble. They are the signs in the emotional sphere which show that an active struggle is in process inside that individual in his attempts to wrestle with his problems. At the end of the few weeks of crisis these symptoms will disappear, once some kind of solution has been achieved. This solution may be a healthy one. On the other hand it may be an unhealthy one, and in that case either at once or in the future the individual will manifest neurotic or psychotic symptoms which represent a pathological way of dealing with his life problems through some form of irrational and psychologically distorted pseudo-solution.

The most important point for preventive psychiatry is that the type of problem solving during a crisis can be powerfully influenced by the helpful or hindering intervention of other people, both in the family circle and from the outside, in the form of the physician and other community agents. When the balance of forces is upset in a crisis a minimal intervention may produce major and stable results by determining to which side the balance will come down.

This means that the operations of the family physician during any of his visits for whatever reason to a family in crisis may have a major effect on the pattern of resolution of that crisis and on the members' future mental health.

I wish now to concentrate on examples of certain practical implications for the operations of the family physician that arise out of these theoretical considerations.

Safeguarding the Integrity of Family Structure

The general practitioner has many opportunities in his practice to help keep families from breaking up temporarily or permanently; or, if this can not be avoided, to help them find substitutes for roles which the family break-up has left vacant.

Most important is the prevention of separation of the mother from the family circle or from one of her children. Bowlby[1] and other workers have shown fairly conclusively that the separation, for any appreciable time, of the stable mother figure from a child during the first few years of its life exerts a damaging effect on the development of the child's personality, leading in severe cases to extreme forms of psychological and psychosomatic illness. If the physician is aware of this, he will be alert to explore practical alternatives to any plan for removing a mother or a child from the home because of illness. Often the removal from home is quite inevitable because the nature of the illness demands hospitalization, but frequently the physician may be able to plan for this absence to be short and for the remainder of the treatment to be carried out at home. The fact that the mother is physically incapacitated certainly will influence her ability to fulfill many of the demands of the mother role, but her mere presence in the home will allow her, through repeated contacts with other family members, to maintain the emotional bonds of comfort and sympathy and mother love which are the emotional nutrients the others need.

Of course such a plan implies the need for nursing and homemaker services to care for the patient at home and to take over her housewifely duties. The physician should be active in helping the family secure such services either from the ranks of the extended family of grandparents, aunts, sisters, and cousins; from neighbors and friends; or, if these are not available, from professional workers. When the latter are not available I believe that local physicians should actively campaign among appropriate community agencies for their provision. Family physicians should be as interested in the adequacy of community agency provision in this area of homemaker services as they are in the standards of their local hospitals, since both affect the quality of the professional care they can give their patients.

The feeling in regard to hospitalization of young children should be that of avoiding or postponing or shortening it whenever possible. With modern methods of diagnosis and treatment and effective home nursing, many types of cases which in the past necessitated admission to children's hospitals can be treated at home.

When separation is inevitable the physician should encourage frequent and regular visiting to maintain channels of communication and continuation of the emotional links.

In 1952 in England, as a result of Bowlby's researches, the Ministry of Health issued a directive to permit and encourage daily visiting in children's wards. In the United States this is also becoming common pediatric practice, and some new children's hospitals have facilities for parents to sleep in the ward near their child and help with certain nursing procedures. This has led to inevitable complications in ward management and new problems for the nursing staff, but none of these have proved insoluble and they are a small price to pay for the results in terms of the safeguarding of the personality development of the children.

The physician interested in the whole family should also be on the alert for the neglect of the other children when one child is hospitalized. He should try to mobilize the efforts of other family members to cover the hiatus left when a mother is concentrating her efforts on the ill child, and his activity in this regard should not stop when the ill child comes home. We are familiar with many cases of neurotic disturbance in children which started during periods of parental neglect due to the illness of a sibling.

If the mother has to go into the hospital, the physician should try to promote communication from her to the other family members, particularly the children, through frequent verbal and written personal messages; he should also use his best efforts to help the rest of the family stay together in their home. If the family stays together they may close their ranks and take over, as a group, some of the absent member's functions, whereas if they are split up this group strength is dissipated.

In order to keep the family together the physician may have to mobilize other family members to come in and do the housekeeping, or he may have to call in a homemaker. Placing the children as individuals in other homes may seem the easier way, but it is actually more expensive in both the short run and the long run.

Another area where the family doctor can give invaluable mental health help is that of helping the father take over some of the maternal role left vacant by the absence of his wife. Husbands may need support and explicit encouragement and advice in mothering their children during this period and in assuming unaccustomed leadership in housekeeping. Some men may be rather inhibited in doing what is needed because of false feelings of shame about such activities being effeminate. The physician can watch out for this and throw the power of his prestige behind the medical prescriptions to the hesitant father.

When the separation of the mother is permanent due to death or desertion the physician should interest himself actively in helping the family plan for her replacement by a substitute. Assistance in this direction, as in the other issues which have been mentioned, may be obtained from a family social agency; but the family physician, who is the professional person with continuing contact and responsibility for the whole family, should help in mobilizing this assistance and should coordinate these activities with his own and with those of other helping agents such as clergymen and teachers.

The physician should be equally active if it is the father and not the mother who is separated from the family by illness, death, or social factors, such as employment demands or wartime needs. A wife needs her husband's support, and children need the controlling influence of a father figure. This issue has been relatively neglected until recently. Interest in it has now been aroused by the realization that many common disorders of personality development in children, which lead to delinquency, have been influenced by the absence of a stable controlling father during the child's upbringing, so that the external discipline which is the precursor of the internal discipline of the socialized person has been missing or defective.

If there is no man in the house, the role of discipliner of the children devolves largely on the mother, and she may need the support of the physician, himself a potent father figure, in order to add this to her other roles. It may also be possible for him to help her out directly in certain crisis situations and to invoke the help of teachers and recreational group leaders.

Perhaps by now it seems that I am advocating turning the general practitioner into a social worker. Nothing is further from my intention. His primary role must remain that of the practitioner of the healing arts; but if our talk of treating the whole person rather than the diseased organ is to be more than a mere slogan, we must expect the physician to add an interest in some of the above psychosocial points to his traditional preoccupation with physical functioning. The family physician may well realize that his role in the family provides him with both the responsibility and the opportunity to affect its functioning in ways which will have direct effects on the health of its members. So long as mental health and mental illness were conceived of as being quite separate from physical health and physical illness, the physician could afford to neglect some of these issues; but nowadays such a dichotomy is hard for most of us to accept and very hard indeed for the general practitioner who deals not with bits of people or special aspects of their functioning, as isolated in special clinics, but with the whole fabric of life within the family circle in the home.

Safeguarding Healthy Relationships

The satisfaction of individual psychological needs in the family is dependent not only on the preservation of the integrity of its structure but also on the quality of the enduring interpersonal relationships among its members. The mother may not be geographically separated from her child, for example, but her prevailing feelings toward him may be so anxious, ambivalent, or rejecting that she cannot perceive his needs, or, if she does, she may have no interest in satisfying them.

Once disordered relationships between family members have fully developed, treatment by a psychiatric specialist is usually needed to improve them; unless such intervention is forthcoming, a significant proportion of the people will eventually need psychotherapy for manifest psychiatric illness. In the past few years, however, we have discovered that the disordered relationships which are harmful take quite a time to develop to their full pathogenic intensity and that during this period the family physician may interrupt this harmful development. His helpful intervention can best be focused at certain crucial periods when disorders in relationships are most apt to occur in response to characteristic temporary situational factors.

Pregnancy.—One such crucial period, both for the development of the mother-child relationship and for the other interpersonal relationships in the family, is the period of pregnancy. The mother's relationship with her new baby does not begin at his birth but is being built up during her pregnancy; the complicated metabolic development of this period has a characteristic effect on her emotional functioning, which in turn has reverberations on the emotional life of the family as a whole. These reverberations may lead to changes in the way the family members relate to the expectant mother and to each other, and these changes may become stable and may have far-reaching consequences for mental health by altering the pattern of need satisfaction within the family circle.

Recent studies [2] on the emotional manifestations of normal pregnancy have yielded information about characteristic series of emotional changes which occur in many expectant mothers and which are apt to frighten them and to interfere with family life. The physician who knows the details of this predictable development may make powerful use of this knowledge.

His main technique will be anticipatory guidance, whereby he warns the patient and her husband ahead of time what to expect and thus gives them the chance of preparing themselves psychologically for the difficulties. For instance, quite early in pregnancy the physician should have a joint interview with husband and wife and let them both know that many women become more irritable and more sensitive than usual during pregnancy because of complicated and little-understood somatopsychic factors; therefore, if in this case the expectant mother suddenly gets angry with minor provocation, laughs or weeps for no adequate reason, or has sudden attacks of depression, neither she nor her husband need get alarmed. These changes, however dramatic, are not preliminary signs of psychiatric illness and they will disappear after delivery.

At this early conference the physician will also be well advised to mention the likelihood of changes in the pregnant woman's sexual desire and performance. Changes in appetite are frequent in pregnancy, and this relates not only to foods but to sex. In regard to this topic the physician not only gives needed anticipatory guidance but often is able to act as a channel of communication between husband and wife in relation to topics which in our culture may not be easily discussed between them. In the absence of necessary knowledge and in the presence of communication blocks so that difficulties cannot be worked out by discussion, tensions may easily arise between husband and wife based on distorted interpretations of each other's attitudes. A wife, not infrequently, gets very upset if she loses her sexual desire or capacity for orgasm; she imagines she has become permanently frigid or that she is losing her love for her husband and that he will reciprocate in kind. A husband sometimes fears that his wife is rejecting him because he made her pregnant, and sometimes he seeks alternative sources of sexual satisfaction as a reaction to this imagined rejection. Such unfortunate fantasies can be easily alleviated by the physician's prior discussion of the realities of the situation. He can also help both parties become aware of the strain under which each will be laboring during pregnancy and help them pay special attention to the need to support and sympathize with the partner's difficulties and to make allowances for signs of tension.

Such joint interviews with husband and wife, which should if possible be repeated at least once or twice more during the pregnancy, have a more essential function than just the smoothing out of expected difficulties in the marital relationship, important as this is. My studies have shown that toward the middle of pregnancy most women become more passive and demanding of affection than usual. Instead of being the giving person in the home, actively attending to the needs of others, they now turn in on themselves and feel the need to sit around and be waited on. My studies have also shown that the adequate satisfaction of these needs for increased attention and affection is not only important for increasing the expectant mother's comfort but also plays an important part in preparing her for adequate motherhood in the first few months after delivery. If she receives enough affection during pregnancy, she can give out enough affection to the baby. Those women who are deprived during pregnancy later have a tendency to deprive their babies.

Recognition of this by the physician allows him to play an important role in ensuring adequate emotional supplies at the crucial early period of the newborn infant's life. He cannot give the expectant mother affection himself, but he can try to make sure she gets it from the natural sources. There are many cultural and psychological factors which may block a husband's demonstrations of affection during pregnancy. He may be so irritated by his wife's petulant behavior and by her inability to afford him his usual sexual satisfaction that he turns away from her. He may be frightened by her increased demands, and he may feel she is changing her personality and becoming lazy and spoiled. He may resent what he feels is her exploitation of the privileges of pregnancy. His feelings of security in his manly role, which are in our culture often weakened by the lack of respect we pay to expectant fathers, may be further endangered by his wife's demands that he take over some of her maternal functions in the work in the house or caring for the other children.

The physician has the opportunity during his joint conferences with husband and wife, or if necessary during an individual interview with the husband, to prevent the difficulties which may emerge from these factors. He can reassure the husband as to the normality of his wife's reactions and as to their temporary nature, and he can enlist the husband's active help in preparing for the baby by, as it were, "charging up his wife's battery of affection," so that she can eventually pass the emotional supplies on to the baby. Most important, the physician can by his own attitudes during these meetings help increase the husband's feeling of respect for the importance of his own role as an expectant father. This may help to prevent a not infrequent cause of family difficulty after the baby arrives, when some fathers are hampered in their paternal role by feelings of jealousy in regard to the baby.

I do not wish to leave this very brief reference to the physician's preventive role in emotional disorders originating during pregnancy without mentioning the results of some recent research which has specific practical implications. My studies have shown that certain traumatic events occurring during the period of pregnancy exert a powerful harmful effect on the future mother-child relationship. Such events include the severe illness or death of a near relative of the expectant mother, particularly of a parent, her husband, or one of her children. It is very easy for the woman to displace some of her painful feelings about such an event onto her relationship with her unborn child, and her attitudes toward him get distorted by irrational ideas, such as identifying him as a reborn representative of the dead person or blaming him and sacrificing him because of unresolved feelings of personal guilt in connection with the bereavement. The physician should be especially on guard to ensure an adequate process of mourning along lines I will describe below, and he should help the mother to see and to feel that her new baby is an individual in his own right and has to be recognized and treated as a person with quite a separate fate from everyone else, including the dead person.

Abortion.—Another traumatic event during pregnancy which is likely to have a major harmful effect on the future mother-child relationship is an attempt by the mother to abort herself, if this act is against the rules of her culture and traditions, and especially if she keeps it as a guilty secret. It is this guilt which blossoms in secret fantasies and which invades and distorts the relationship with the child. If nothing is done about it, the chances are high that a particularly pernicious disorder of the child's personality will eventually be produced. The important point is that this pathological sequence of events can usually be easily interrupted by the family physician, if he identifies either during pregnancy or soon afterward what has happened. The technique to be used is one which is not usually a part of the general practitioner's therapeutic armamentarium but one which can be fairly easily learned, namely, specific reduction of conscious guilt. I have discussed this at some length in a recent paper,[3] and here I will only mention it briefly. It consists essentially of the physician helping the woman to talk about what she has done in two to three short interviews, in which he adopts an understanding and nonjudgmental attitude toward her behavior, without in any way pretending that what she did was a good thing and yet with the clear demonstration that despite what she has done he continues to accept her as a worthwhile person.

Direct Help to People in Crisis

The traditional role of the physician brings him into contact with many people during the critical period when they are wrestling with acute life problems, and at such times he can exert a particularly powerful effect on their mental health by steering them toward adequate solutions and away from maladaptive solutions. The clearest example of this is in connection with problems of bereavement.

Bereavement.—Eric Lindemann,[4] my colleague at Harvard, has carried out some interesting studies on the nature of the process of mourning which carry clear and specific implications for medical practice. He has found that a bereaved person goes through a well-defined process in adapting to the death of the relative, that this process usually takes four to six weeks to complete, and that it is characterized by a succession of specific psychological steps with accompanying emotional side-effects. It seems that when a key figure is removed by death or desertion from a person's life, that person has to work quite hard, psychologically, in order to adapt to the loss and in order to fill in the resulting emotional hiatus.

Lindemann also found that whereas the majority of people manifest these characteristic mourning reactions, which show they are satisfactorily doing their "grief work," and recover their psychological and psychosomatic equilibrium by the end of the four to six weeks, a small but significant group of bereaved people do not show these changes, or show them in distorted form; many of these people either immediately or later show definite and sometimes extreme signs of psychiatric or psychosomatic illness, particularly depression and disorders of the gastrointestinal tract, such as peptic ulcer or ulcerative colitis.

Lindemann postulates a direct causative link between the absence of a normal mourning process and the later development of these illnesses. He has also shown that sometimes these illnesses can be interrupted by helping the patients revive the problems of their bereavement and belatedly do their undone grief work.

Among the characteristic manifestations of a healthy mourning reaction are withdrawal of interest from the affairs of daily life and business, feelings of mental pain and loneliness, weeping, disorders of respiratory rhythm with frequently repeated deep sighs, insomnia, loss of appetite, and —most characteristic—preoccupation with the image of the deceased person, usually in connection with the revival of numerous memories of joint activities with him. Lindemann feels that this last phenomenon is the key to understanding the essence of the mourning process. The bereaved person withdraws his energy from most of the aspects of everyday life and concentrates it on reviewing, detail by detail, those aspects of his past life which were enriched by his association with the deceased. In each of these life segments he has to realize afresh the pain of his loss and rather concretely to experience its permanence. In each of these segments he has to make a special act of resignation to the inevitable. This can only be achieved through suffering, but not until it is completed can the person achieve mastery and independence in that segment of his life, so that he can return to normal activity and emotional stability.

Each bereaved person must do this grief work for himself, and mourning is a lonely process; but the traditions of most cultures illustrate to us that neighbors and friends and representatives of the larger community can help the mourner both by the general emotional support of condolence and by practices which permit him or encourage him to go through the steps of his grief work. In our modern culture the weakening of religious and other cultural systems of values and traditions has thrown many people largely on their own emotional resources, and the family physician is one of the people whose work may call him to step into the breach. In doing so in this area he may well try to enlist the support of the priest or clergyman or rabbi, each of whom has his own traditional approach to these problems.

In order to understand specifically what the family physician might do to help the bereaved person mourn successfully, it is helpful to list some of Lindemann's findings among the unsuccessful mourners, who later developed various illnesses. No single simple picture was characteristic of this group, but combinations of the following reactions were common. Instead of withdrawing interest from daily life many of them showed more business activity than usual and by diverting their interest to the problems of outside life appeared to escape the inner turmoil of mourning. They did not weep. They felt little or no pain, either saying they felt numb and empty or showing a strange cheerfulness. Many of them showed marked hostility, often directed toward the physicians and nurses who had cared for the deceased. In all cases there was an absence of preoccupation with the deceased, and on direct questioning many said they were quite incapable of recalling in memory the image of the deceased person. The over-all picture which was most commonly found was an attempt to deny the emotional importance of the whole business and to get on with problems of living without the burden of mourning. In the short run the external emotional manifestations of this group seemed easier and happier than the group of active mourners, but in the long run many of them paid very dearly for their temporary ease.

The guideline for the physician who wishes to profit from these studies is to try and help his patients grieve along the lines of the first group and to be particularly active in giving his help whenever he recognizes in one of his patients, during the mourning period, signs which resemble those of the maladaptive group. Experience has shown that to help such people grieve successfully it is not necessary to know the inner psychological reasons for their being hampered in this regard. The uncovering of these deeper complications is not necessary; all that seems important is to get them by whatever means to dwell on the image of the deceased and to go over and over in their minds the many activities which they shared with him in the past, in order little by little to realize that from now on he will be missing from their lives. What is also necessary is for the physician to give the patient the full measure of his emotional support and sympathy in bearing the pain of this process and for him to mobilize other sources of support within the family and outside it. In this regard the physician should realize that emotional support depends, among other factors, on the quantity of personal interaction, so he should realize the special importance of even short extra visits to his patient during the mourning period, or, if these are not possible under the pressures of a busy practice, at least of phone communication. Since the pathological sequelae of inadequate mourning are usually so severe, these extra visits are well worthwhile.

When the physician is not able on his own to stimulate a proper mourning reaction, when his efforts to enlist the aid of ministers of religion and members of the extended family also lead nowhere, and when mourning is absent or continues without apparent resolution long after the expected period of four to six weeks, the physician would be well advised to take active steps to refer the patient to a psychiatrist at that stage and not wait for the psychiatric illness to develop. This is a situation where a specialized "stitch in time" may well "save nine."

Other Crises.—Space does not permit me to go into detail about other examples of direct help by the physician to people in crisis, and I hope that some general principles may have emerged from my discussion of help with bereavement. I wish, however, to make brief supplementary mention of two other crises commonly met in medical practice, the crisis faced by parents who have to adapt to the realization that their baby has a congenital abnormality or is mentally defective and the crisis of a patient or his relatives having to adapt to a chronic or an incurable illness, a major disability, or to death itself. These situations all call for special activity on the part of the physician, in addition to the customary "frank" or "not so frank" talk.

The physician must face the fact that the impact of the news of the diagnosis is likely to be followed by a period of psychological reorientation similar to the grief work of the mourning period and interestingly enough also lasting for about four to six weeks. Patients and their relatives should not be expected to handle these psychological burdens on their own. They may need a good deal of support from the physician in facing the painful implications of the situation and help in avoiding facile escape into denial or obliteration of the problem by wish-fulfilling fantasies. The physician should try to help them keep the problem in consciousness during this period and deal with its implications piece by piece. It is remarkable the power that ordinary people have to adapt to reality, however unpleasant. It is not realities but dreams which "make cowards of us all," and insofar as the problem is allowed to sink into dreams and into fantasies it gets removed from the strength which derives naturally from our universal adaptive mechanisms.

On the other hand, the physician should realize that in its initial impact a problem may be quite overpowering and some partial or initial denial is a fundamental defense mechanism. He should not interfere with this, nor with the occasional rest periods during the adaptation process when the patient tries for a while to forget his problems by diverting his interest to other matters. In fact the physician who knows his patient may be able to recognize when he is becoming too fatigued by facing the unfaceable, and he may then prescribe a temporary respite by diversion or drugs. He should be on the alert, however, to call a return to the fray once the rest period has resulted in the replenishment of resources.

I would like to sound here a word of warning against the indiscriminate and continuous use of tranquilizing drugs for people in crisis. Studies are at present under way to determine not only their pharmacophysical ill-effects but also their possible psychological complications; among the latter I predict we will probably find that, by damping down too drastically the impact of crisis situations, tranquilizers may be preventing the active processes of healthy adaptation to important life difficulties and thus laying the stage for subsequent psychiatric illness.

Need for Psychiatric Consultation

The family physician who seriously wishes to enlarge the scope of his practical operations in order to cater to the mental health needs of his patients and their families would be well advised to build up a collaborative working relationship with a psychiatrist of his choice. If a psychiatrist is not available, such help can also be obtained from a well-trained clinical psychologist or a psychiatric social worker. The important thing is wherever possible to use the same person each time, so that the two can learn each other's language and ways of working.

In talking about consultation I do not have in mind the occasional necessity to refer a patient with some psychiatric illness to a specialist for investigation and treatment. This will certainly be necessary, and the more sophisticated the family physician becomes in dealing with emotional problems in his patients the earlier he will be able to identify such conditions and the more easily and surely he will be able to effect the referral procedure.

More Effective Understanding and Management.—The kind of consultation I am particularly referring to here is different: it is consultation by the general physician with the psychiatric specialist in order to enlist the latter's help in rendering the family physician's own understanding of the case and his own management of it more effective. However well trained the general physician may be, he will inevitably come across situations involving the emotional life of his patients which are outside the area of his previous learning and experience. The psychiatrist may, by discussing the case with him, be able to enlarge his understanding and to deepen his insight by pointing to the relevance of certain items of information about the field of forces which the physician had previously ignored. The psychiatrist's specialized knowledge of patterns of intrapsychic functioning and unconscious motivation may allow him to explain previously puzzling aspects of the patient's personality and that of his relatives which throw new light on their behavior and afford new opportunities for helpful action by the physician. It is very important for the doctor to tailor his intervention in the family to the special individual personality characteristics of its members. Most family physicians will build up a store of relevant knowledge of the weaknesses and strengths of their patients from their years of experience with them, but every now and again there will be some reactions which are quite unexpected and the physician may find his best efforts frustrated. On such occasions the psychiatrist's knowledge of the deeper unconscious aspects of personality functioning may clarify the situation so that the physician may find a new way to help his patient.

Improving Use of the Self.—Another type of help which the physician may expect from the mental health consultation is that of sharpening and improving his own use of the self in his professional medical functioning. A physician constantly makes use of different aspects of his personal influence on his patients as part and parcel of his daily work. This use of the effect of one human being who is being helpful on another who is in need becomes especially important in dealing with those needs which are predominantly emotional rather than physical.

Unfortunately, although physicians make use of personal influence all the time in their medical practice, this usually remains an amateur, somewhat haphazard set of operations with most physicians rather than a consciously directed professional therapeutic instrument. Some physicians have a more consistently therapeutic personal effect on patients than others, and we ascribe this to innate personality gifts or to a generalized "bedside manner" of uncertain origin. Even these physicians often fail in their efforts to support or stimulate or reassure certain patients, and when they fail they can no more understand why this has happened and deal with the consequences than they can understand their successful cases. The average physician is no better off when it comes to understanding his own special emotional reactions to certain patients—his feelings of liking and warm protectiveness, his irritability and anger, his frustration, his anxiety, or sometimes his guilty withdrawal. He does his best to control these feelings and not allow them to interfere with his objective medical approach, and his training usually helps him to succeed—but often at the expense of becoming rather distant and cold. It is the rare general physician who is able to capitalize consciously, both for diagnostic and for therapeutic purposes, on his awareness of his own feelings as they are stimulated by the behavior of his patient.

The psychiatrist, on the other hand, has by a long and arduous training not only learned to know and accept his own human reactions in his reciprocal interaction with his patients but he has learned to make explicit and differentiated use of them in the professional setting. Through the consultation process the physician may gain from him some understanding and skill in this matter. This will only come gradually, which is another reason for working with the same consultant over a lengthy period. This is not a matter of the giving or the receiving of intellectual prescriptions but the emotional education which comes from numerous discussions about the details of practical life situations and one's feelings about them.

Consultation, a Two-Way Process.—So far I have talked as though the psychiatrist were the teacher and the family physician the pupil in the consultations, and to some extent this is so; but the physician who imagines that all he will have to do is to ask questions and get the answers from the psychiatrist will be sadly disappointed. He will quickly discover that with all his specialized knowledge the psychiatrist does not have many answers to the circumscribed questions about the practical issues of management of ordinary patients in the situation of general practice.

I said before that mental health consultation is a joint collaborative endeavor, and what I meant to imply is that it has to be a two-way process, in which not only the psychiatrist but also the physician must be an active partner. It is essential for the physician to realize that he must take active steps to educate the psychiatrist during these consultations so that he will understand the special nature of the management problems involved, which will be quite different from what he is used to in the very unusual circumstances of his psychiatric clinic or office practice. Working with the same psychiatrist over a period of time the physician may be able to teach him enough about the daily problems of general practice and the life situations of ordinary people who do not consider themselves psychiatric patients that he can eventually get answers which come reasonably close to being useful, but he will usually have to work quite actively to take what the psychiatrist has to offer and to translate it for his own use.

A psychiatrist who has himself had experience in general practice before undergoing psychiatric training sometimes finds this type of consultation easier, but it is surprising how specialized psychiatric training and experience, which dwell constantly on the abnormal and the unusual and on unconscious motivation and irrational fantasy formation, impair the memories of this previous experience with the world of normality. A psychiatrist usually realizes the extent to which this is so and realizes and respects the degree of expertness of the family doctor's specialized knowledge in his own field only after he has been educated by his consultee.

I can vouch personally for the importance of this process because in the course of my own experience in community psychiatry I have been successively educated by social workers, public health nurses, pediatricians, obstetricians, and nutritionists, most of whom were initially a little surprised to find how much they were teaching me during their consultations.

Responsibility for Plan and Implementation.—This leads me to my last point. The management plan which emerges from the consultation may have been arrived at as a result of a fruitful joint collaborative endeavor, but the type of plan and the responsibility for its implementation must remain with the family physician and must fit into the general framework of his traditional methods of functioning. Both parties should beware of working out a psychiatrist's plan instead of a family physician's plan and of turning the physician into a "proxy psychiatrist." The style of work of the family physician is fundamentally different from that of the psychiatrist.

For instance, take the time relations of their professional work. It may seem that a busy general practitioner would never have the time to make use of the kind of knowledge I have been discussing in this paper; he could never spend the time which the psychiatrist can apparently allot to his small select group of patients. This is a red herring. It presupposes that, to cover the same problem, members of the two professional disciplines will use the same approach. This is neither necessary nor desirable, since the different professional roles have been differentiated over a long time in order to cope with problems in a very special way which has been found empirically to be effective and which is recognized by being embodied in the traditional culture of that profession. In this case, for instance, the practices of the psychiatrist in relation to time are based on the fact that his patients are strangers to him; since he has to penetrate below their surface defenses and deal with unrecognized and unacceptable material, his relationship with his patient, however intimate the content of their discussions, remains a highly structured stranger relationship, in which each takes care to keep outside the boundaries of each other's customary social life. The regular appointment and the 50-minute hour are derivatives of this situation, the interview between patient and psychiatrist being specially separated from the rest of the patient's life so as to give him the security to lay down temporarily some of his defenses. The length of the usual psychotherapeutic treatment is also dictated by the fact that the psychiatrist has to deal systematically with much complicated material in working down from the surface of consciousness to those hidden areas in which he searches for the unconscious sources of the illness.

The family physician by contrast knows many of his patients as friends. He has known them and their relatives for years, and even in the case of a new patient he can assume that this will be a prolonged contact. He does not need to collect important information about the personality of his patients in a few long highly structured interviews; it comes in dribs and drabs, either directly or indirectly from many and various collateral sources. He penetrates the patient's social life and home as a friend, and very often his patients come into his own home as a friend. Certainly he learns many secret and intimate things about his patients, but the level of such knowledge and the confidence in professional secrecy are such that this rarely leads to a patient feeling the need to hide from the physician in social situations.

Finally, one must realize that, in helping his patient handle emotional problems of the crisis type I have referred to, the family physician does not need to make long speeches. The most powerful interpersonal messages in which one person influences another are often very short. When the time is ripe at the height of the crisis, the right word or the right few words in the right place give better results than a lecture. Often it is a brief aside or an implication of some statement which ostensibly deals with some detail of management of a physical symptom which does the trick. Very often the most powerful messages are conveyed without words—by one's understanding manner, by one's patience, by one's warmth of greeting, or by a sympathetic nod or gesture. These do not take time, and these are the stock in trade of the physician. The results will be determined by their appropriateness in relation to the specific condition of the patient in his current predicament; but if success is only partial the family physician can always rely on being able to wait for additional opportunities in the future, since his relation with his patient will probably be continuing for many years to come. Through his consultations with the psychiatrist, he will gradually become more and more skillful in these areas. I believe that this skill is a main prerequisite for success in preventing emotional illness in our communities.

RESULTS OF ADDITION OF LIOTHYRONINE TO A WEIGHT-REDUCING REGIMEN

E. Philip Gelvin, M.D., South Orange, N. J., Samuel Kenigsberg, M.D.
and
Linn J. Boyd, M.D., New York

The effectiveness of liothyronine as part of a weight-reducing program was investigated in a number of obese patients who were taking a standard 1,000-calorie diet. A preliminary study established 75 mcg. per day as a safe dose. The final study involved 57 patients who took the same diet together with a d-amphetamine-amobarbital preparation for two eight-week periods. Group 1 (28 patients) in addition received a placebo during the first period and liothyronine during the second, while group 2 (29 patients) received liothyronine during the first and the placebo during the second period. No significant difference was found between the two groups during the first period, but during the second period group 2 ceased to lose. Group 1, receiving liothyronine during the second period, continued to lose, and for this group the weight-reduction amounted to 0.39 kg. (0.86 lb.) per week for 16 weeks. Liothyronine was of great help to patients who could not maintain an adequate rate of weight loss on the established regimen.

Desiccated thyroid has enjoyed great popularity as a weight-reducing agent for many years by those who believe that diminished activity of the thyroid gland is a frequent cause of obesity. However, although a gain in weight has been attributed to a low level of metabolism, recent studies have demonstrated that hypothyroid and even myxedematous patients are not necessarily obese. Indeed, when the weight of their excess fluid is discounted, they may be underweight.[1] Thus hypothyroid patients are not necessarily obese, and most obese patients have normal thyroid function.

Thyroid has also been used as a "general metabolic stimulant" for the purpose of burning up excess fat. However, while the consistent, predictable effect of thyroid in increasing metabolism in myxedema is well known, its calorigenic effect in euthyroid persons is not so certain, and its use in the treatment of obesity has been disappointing. It has been demonstrated repeatedly that weight loss induced by means of thyroid hormone can only be accomplished by administering this drug in amounts sufficient to produce toxicity; the dangers inherent in prolonged treatment of this kind are obvious.[1]

Johnson and co-workers[2] studied the effect of increasing increments of thyroid in euthyroid patients and reported that it was extremely difficult to bring about a permanent elevation in the basal metabolic rate. On a dosage of 2 grains (0.12 Gm.) a day there was an early rise in the basal metabolic rate and then a gradual fall. When the dosage was increased to 4 grains (0.25 Gm.) daily the metabolic rate again rose, and on prolonged administration it again fell, but not to the original level. A few instances of toxicity were noted. On 6 grains (0.4 Gm.) a day there was again an increase in metabolic rate. The rate again declined, but became stabilized above the control level. Toxic symptoms were frequent. At a dosage of 6 grains daily some subjects began to lose weight but suffered from increased fatigability, malaise, and palpitation. There were great individual variations in the tolerance to thyroid among the subjects. Some could not tolerate 3 grains (0.2 Gm.) a day, while one patient noticed no ill-effects while taking 10 grains (0.6 Gm.) a day. This latter patient, incidentally, gained weight while taking such an enormous dose of thyroid.[2] Because the effect of thyroid in producing weight loss in euthyroid patients is inconstant and unpredictable, we have discontinued this use of it.

In line with the discussion of thyroid as a general metabolic stimulant, mention should be made of dinitrophenol. This drug was introduced in 1933 and enjoyed widespread but brief popularity as a metabolic stimulant for use in weight reduction. Theoretically, it should have been very effective because of its ability to increase selectively the oxidation of fat. However, because it produced a high incidence of toxic effects, it rapidly fell into deserved disrepute and its use has been abandoned.

Triiodothyronine differs from thyroxine in the absence of one iodine atom in the 5′ position (fig. 1). Three forms of the hormone have been found to exist: D-, DL-, and L-triiodothyronine. L-triiodothyronine, known as liothyronine, is the most active. It is three to five times as active calorigenically as thyroxine, depending on the method of assay.[3]

Liothyronine acts much more rapidly than thyroxine or desiccated thyroid. The effects of liothyronine become apparent clinically within 24 hours after administration. Similarly, the duration of liothyronine activity after cessation of treatment is about 2½ days, compared to from 6 to 12 days for

---

thyroxine.[4] Liothyronine exerts a more rapid suppressive effect on the radioactive iodine uptake of the thyroid gland than does thyroxine, and its effects are more rapidly dissipated on discontinuation. For these reasons Werner feels that liothyronine is preferable for use in conjunction with the radioactive iodine uptake in differentiating euthyroidism from hyperthyroidism.[3]

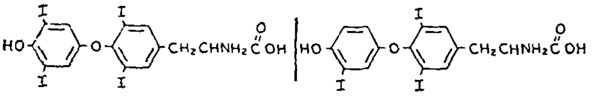

Fig. 1.—Chemical formulas for *left,* thyroxine, and *right,* triiodothyronine.

The level of the serum protein-bound iodine (PBI) is only slightly influenced by liothyronine. Starr and Liebhold-Schueck[5] found it produced a slight fall in PBI concentration. Thyroxine and desiccated thyroid, on the other hand, produce a rise in PBI concentration. The reason for this unusual effect of liothyronine is not known for certain. It has been attributed to (1) rapid egress of liothyronine from plasma into the peripheral tissue cells, (2) rapid degradation and excretion of liothyronine, and (3) lessened peripheral demand for hormone ordinarily produced by the thyroid gland, which results in a decrease in such production resulting from the inhibition of pituitary thyrotropin by liothyronine.

The exact synthesis of liothyronine in vivo has not been defined. It has been postulated that it is formed by the enzymatic deiodination of thyroxine in the peripheral tissues and that it is the active thyroid hormone.[6] Starr[5] believes that both thyroxine and liothyronine possess thyroid hormone activity. In normal situations thyroxine maintains caloric homeostasis, while under stress or emergency conditions liothyronine is produced at an increased rate from thyroxine.[5] Because liothyronine has been shown to produce a rapid calorigenic response, even in some patients refractory to thyroid or thyroxine, its effects in the management of obesity have been studied. Brügel and Riehm[7] found that diet plus liothyronine produced a greater rate of loss of weight than diet plus thyroid or diet alone. Weidenhamer[8] observed a group of obese patients presenting the clinical picture of "metabolic insufficiency." These were treated with diet and *d*-amphetamine, but after a few weeks weight loss had ceased or become negligible. Addition of liothyronine to the regimen resulted in a resumption of weight loss. In a detailed metabolic study of the effects of liothyronine in obese persons Bansi and co-workers[9] found that the average loss of weight resulting from use of this medicament was significant and surpassed the values attained prior to its administration.

Preliminary Study

These favorable reports aroused our interest in this use of liothyronine, and a double-blind study was planned to see whether the published results could be confirmed. However, before a double-blind study could be undertaken, it was important to know what dose would produce good therapeutic results without causing side-effects. It was also necessary to know whether the age, basal metabolic rate, and blood pressure of each subject would influence this dose, and so we conducted a preliminary study.

Fifty-five outpatients at the obesity clinic of the Metropolitan Hospital, New York City, were selected for the preliminary study. The standard clinic 1,000-calorie diet was prescribed for all patients. In addition liothyronine was prescribed in an initial dosage of 25 mcg. a day. Patients were seen biweekly, at which times they were asked about the development of side-effects. If none were manifest, the dose was increased by 25 mcg. daily. If side-effects had developed, the dose was decreased by 25 mcg. or more depending on the severity of the side-effects. In this manner the maximum daily dose of liothyronine which would not cause side-effects was determined for each patient.

When the amount of liothyronine administered each day exceeded the tolerable amount, all patients developed one or more mild side-effects. The side-effects were nervousness in 11 patients, tachycardia in 10, hunger in 8, palpitation in 7, insomnia in 7, dizziness in 4, headache in 4, angina in 2, abdominal distress in 2, and shortness of breath, tremors, leg cramps, and vomiting in one patient each.

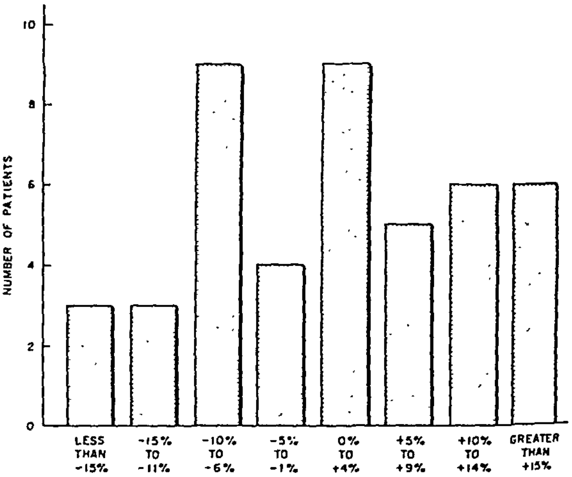

Fig. 2.—Distribution of basal metabolic rates before therapy in patients in first study.

At each return visit, the patients' weight, pulse rate, and blood pressure were recorded. A determination of the basal metabolic rate was requested for each patient prior to the initiation of liothyronine medication, for the sake of completeness of the data as well as to satisfy our curiosity. The results are depicted in figure 2. We are aware that basal metabolic rates cannot be reliably determined by the standard procedures for this measurement in obese persons,[3] but we were interested in learning whether there was any correlation between the basal metabolic rate prior to liothyronine therapy and the rate of weight loss. No such correlation was found (table 1). For this reason, and because in previous studies we had not been able to demonstrate any significant change in basal metabolic rate during weight reduction in a similar group of patients with use of the same diet,[10] the basal metabolic rates were not determined in the subjects whom we subsequently used in the double-blind study.

Table 1.—*Average Weight Loss for Patients in Preliminary Study Related to Basal Metabolic Rate*

	No. of Patients	Av. Time Observed, Wk.	Av. Weight Loss, Lb./Wk.
BMR			
More than −5	30	6.7	0.9
−5 or Less	15	6.9	1.1
Not recorded	10	6.4	1.1
Over-all average	55	6.5	1.0

The distribution curves of the maximum daily dose which could be tolerated without side-effects peaked sharply at 75 mcg. The mean dosage was slightly more than 75 mcg. a day. When the data were analyzed for effects of basal metabolic rate, age, or systolic blood pressure, it was found that patients with a basal metabolic rate of less than −5 who were less than 45 years old and who had systolic blood pressures below 150 mm. Hg were able to tolerate slightly larger doses of liothyronine than could other patients. The differences, however, were small (fig. 3, 4, and 5). An interesting side light of this preliminary study was that liothyronine produced an average weight loss of 1 lb. (0.5 kg.) per week (table 1).

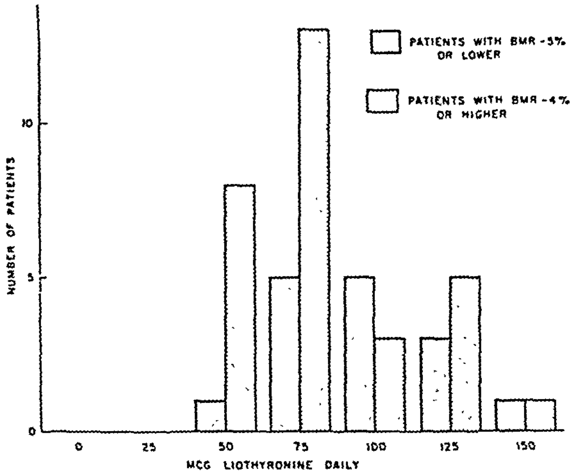

Fig. 3.—Maximum tolerated daily dose of liothyronine as related to basal metabolic rate in patients in first study.

Double-Blind Study

Material and Methods.—This double-blind study was planned to compare the efficacy of a capsule containing *d*-amphetamine and amobarbital in a sustained-release form with a combination of this capsule and liothyronine for the management of obesity under clinical conditions. Fifty-seven patients completed the study, 54 women and 3 men. Their average height was 62.8 in. (159.4 cm.), average weight 193.5 lb. (88 kg.), and average age 43 years. The usual 1,000-calorie clinic diet was prescribed for all patients. This diet allowed 75 Gm. of protein, 100 Gm. of carbohydrate, and 40 Gm. of fat per day.

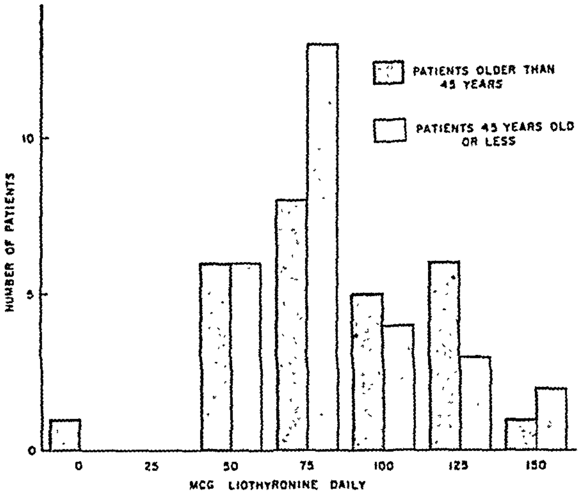

Fig. 4.—Maximum tolerated daily dose of liothyronine as related to age in patients in first study.

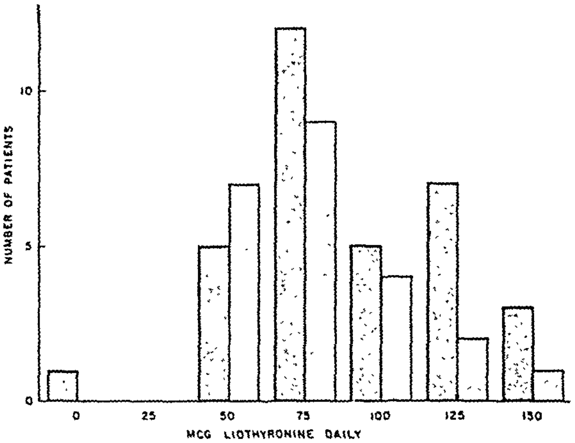

Fig. 5.—Maximum tolerated daily dose of liothyronine as related to systolic blood pressure in patients in first study. *Left-hand columns,* patients with systolic pressure below 150 mm. Hg; *right-hand columns,* patients with systolic pressure 150 mm. Hg and above.

The study was arranged so that half of the patients were started on the regimen of the *d*-amphetamine–amobarbital capsule and half on the combination of this capsule and liothyronine. Schedules were exchanged after eight weeks, so that each patient received each regimen for eight weeks and thus served as his own control. The liothyronine was supplied in pink capsules containing 25, 50, and 75 mcg. of the drug. The *d*-amphetamine–amobarbital preparation was supplied in brown sustained-release capsules containing 10 mg. of *d*-amphetamine and 65 mg. of amobarbital. In the combination regimen the liothyronine doses were increased as follows: weeks 1 and 2, 25 mcg.; weeks 3 and 4, 50 mcg.; weeks 5 and 6, 75 mcg.; and weeks 7 and 8, 75 mcg.

TABLE 2.—*Average Weight Loss, Blood Pressure Level, Pulse Rate, and Cholesterol/Ester Level for Patients in Double-Blind Study*

	Period		
	Pretest	1	2
Weight loss, lb. per wk.*

* Totals: group 1=0.86; group 2=0.58 lb.
† Liothyronine regimen
‡ Group 1=20 patients; group 2=17 patients.

During the period when liothyronine was not given patients received the placebo capsule. Thus the patients took one brown and one pink capsule once each day during the entire 16-week period of observation. The drug coding was arranged so that the liothyronine titration progressed unnoticed, and the investigating physicians did not know the order in which regimens were employed until the completion of the study.

Patients were seen every two weeks. At each visit they were weighed, had their pulse rate and blood pressure recorded, were questioned about their appetite and appearance of side-effects, and were given a new supply of medicaments. In addition serum cholesterol and ester levels were determined in many of the patient during each regimen.

Throughout the description of the results reference will be made to period 1 and period 2 and group 1 and group 2. Period 1 refers to the first eight weeks and period 2 to the second eight weeks of observation. Group 1 consisted of 28 patients who were given *d*-amphetamine–amobarbital during period 1 and this plus liothyronine during period 2. Group 2 consisted of 29 patients who received combined therapy during period 1 and *d*-amphetamine–amobarbital therapy alone during period 2.

Results

Weight Change.—A statistical difference between regimens is demonstrated. The responses in period 2 which favor the combination are fully responsible for this difference (table 2). Statistical tests show no significant difference between the losses of 1.14, 0.88, and 0.84 lb. per week. The total weight loss by weeks for each group is demonstrated in figure 6. Loss of weight ceased after the eighth week in group 2. However, the rate of loss of weight on the combined therapy with liothyronine is relatively constant over the entire study period.

Blood Pressure, Pulse Rate, and Serum Cholesterol and Ester Levels.—Comparison was made between the pretest blood pressure level and pulse rate and those determined at the end of each test period for each group. No significant effect on the blood pressure could be demonstrated by any of the medicaments in the dosages employed in this study, nor was there any significant effect on the pulse rate (table 2).

Considering the large variation from patient to patient, and the technical difficulties inherent in the determination of the level of serum cholesterol,[11] the results are remarkably constant (table 2). Statistical analysis did not reveal any significant differences between the therapeutic regimens in this respect.

Appetite.—At each visit patients were asked about the effect of the medicament on their appetite during the preceding two weeks. An increase in appetite was recorded as a plus figure, and a decrease was recorded as a minus. The scores ranged from +2, moderate increase, to −3, marked decrease. We realize that appetite is purely a subjective phenomenon, and this attempt to quantitate it is of questionable scientific accuracy. We include the

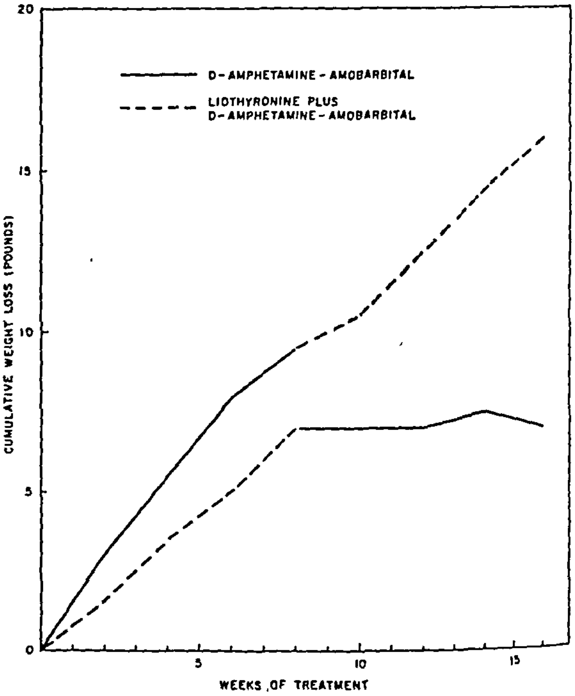

Fig. 6.—Total cumulative weight loss by weeks for all patients in double-blind study.

results merely for the sake of interest and curiosity.

The appetite scores agreed with the weight loss data: For group 1 the average appetite score for period 1 was -0.92 and for period 2 (liothyronine regimen), -0.60. For group 2 the score for period 1 (liothyronine regimen) was -0.52 and for period 2, -0.16. The only statistically significant finding was the very low score (0.16) which occurred in group 2 during period 2.

Comment

The data indicate that both regimens produced equivalent weight changes for the first eight weeks. Thus, the addition of liothyronine added nothing in the early weeks of the study. The last half of the study presented some interesting data favoring the addition of liothyronine. When the combined therapy was given after the *d*-amphetamine–amobarbital preparation alone, weight loss continued at the same rate. Thus these patients continued to lose about 1 lb. (0.5 kg.) per week throughout the entire 16-week period of observation. When *d*-amphetamine–amobarbital was prescribed after the combination with liothyronine, very few patients continued to lose weight and some began to gain. The average weight change for this group of patients was about zero.

In a previous study [12] it was found that when large doses of *d*-amphetamine are given to patients with no dietary restriction, an average loss of weight of at least 1 lb. a week can be maintained for only about eight weeks. After eight weeks there is a rapid decrease in the rate of weight loss.[12] This finding is very similar to the results obtained with the patients in group 2 after the first eight weeks of observation.

Liothyronine may be of help to those patients whose weight begins to level off while on one of the usual weight-reducing dietary regimens. This is exactly what we found in the studies of Brügel and Riehm,[7] Weidenhamer,[8] and Bansi.[9] Their procedure was to prescribe liothyronine after their subjects stopped losing weight. These investigators found that their patients again began to lose weight when liothyronine was added to the basic regimen.

The reason for this effect of liothyronine is obscure. Several investigators have found a decrease in metabolic rate in obese patients on caloric restrictions.[13] It has been suggested that liothyronine prevents this fall in the metabolic rate. However, Werner [14] pointed out that it is not known whether the basal metabolic rate can be increased by the administration of thyroid to obese patients, and many investigators believe that thyroid alone is ineffective in the management of obesity.[15] If it were simply a matter of maintaining the level of metabolism, thyroid should be as effective as liothyronine. Also, it is not universally accepted that calorie restriction in the obese person will result in a fall in the metabolic rate. Rynearson and Gastineau [16] believed that the protein content of the diet is important and stated that it is possible that a generous supply of protein may prevent this fall in the basal metabolic rate. In previous studies we have not been able to demonstrate any significant change in the basal metabolic rate during weight reduction in a similar group of patients with use of the same diet.[10]

With use of much larger doses of liothyronine than were employed in this study Brügel and Riehm [7] and Bansi and co-workers [9] caused a mild degree of hypermetabolism in their patients as measured by the basal metabolic rate and radioactive iodine uptake. Although such determinations were not performed, we noticed no clinical evidence of excess thyroid activity. Certainly no effect on the pulse rate or blood pressure was apparent.

Since the patients in group 2 received the combined therapy with liothyronine initially, it may be questioned whether there could have been a depression of the thyrotropic hormone of the pituitary by the liothyronine. Thus there might have been a lowering of metabolic rate during period 2, which resulted in the failure of these patients to continue to lose weight. It is hardly likely that if there had been such an effect it would have persisted for the entire eight weeks of period 2. After discontinuation of the administration of desiccated thyroid the thyroid gland regains its own function within three or four weeks.[2] The effects of liothyronine are dissipated even more rapidly.[3]

Liothyronine in the dosage we employed did not influence the level of serum chloresterol. Bansi and co-workers [9] reported a considerable reduction in the serum cholesterol level after administration of liothyronine to a group of euthyroid patients. However, he employed an average dosage of 150 mcg. a day, twice that used in this study. Whether liothyronine exerts its effect in weight reduction by correcting a metabolic defect, by stimulating metabolism, by a diuretic effect, or by some as yet unknown mechanism is not apparent.

Summary and Conclusions

The efficacy of therapy with a *d*-amphetamine–amobarbital preparation was compared to therapy with a combination of these drugs and liothyronine when prescribed for the management of obesity. A group of 57 obese patients were studied under clinic conditions with use of a double-blind procedure. Each patient was observed for eight weeks on each therapeutic regimen. Twenty-nine patients received the combination with liothyronine initially, and 28 patients received the liothyronine therapy last. A 1,000-calorie diet was prescribed for all patients.

The two therapeutic regimens produced equal weight changes for the first eight weeks. When the liothyronine combination was given during the second eight weeks of the study, loss of weight continued at the same rate. However, when the liothyronine combination was given initially, there was no further weight loss during the latter eight weeks of therapy with the *d*-amphetamine–amobarbital preparation alone. Thus liothyronine may be of great help to those patients who cannot maintain an adequate rate of weight loss while on a weight-reducing regimen.

At the dosage level of liothyronine used in this study (up to 75 mcg. a day) no effect on the pulse rate, blood pressure, or serum cholesterol level was noted. No symptoms of hypermetabolism attributable to the liothyronine, such as nervousness, palpitation, or tremors, were elicited.

220 Turrell Ave. (Dr. Gelvin).

The *d*-amphetamine–amobarbital preparation was supplied as Dexamyl Spansule No. 1 and the liothyronine as Cytomel by Smith Kline & French Laboratories, Philadelphia.

RINGWORM INFECTION OF SCALP.—In 1941 an epidemic of a highly unpleasant ringworm infection of the scalp of children swept through the major cities of the United States. The epidemic started in New York, and soon after its arrival in Chicago involved about thirty thousand children here. The peculiarity of this infection, caused by the fungus Microsporon audouini, is that it clears spontaneously in adolescence and that the scalp hair of adults is immune to it with very few exceptions. . . . We found that human hair fat contains a large amount of free fatty acids (up to 30 per cent of the total weight of surface fats consists of free fatty acids) and that the free fatty acids inhibit the growth of fungi, especially that of Microsporon audouini. . . . The spontaneous cure of this infection during adolescence can be explained as follows: With the puberal development of sebaceous glands, the amount of sebum poured on the surface of the scalp increases threefold. Thereby the free fatty-acid concentration per surface area is raised beyond the critical level at which Microsporon audouini is able to thrive. The fungistatic sebum enters the loose parts of the superficial horny layer and the hair canals. Once there, it sterilizes all the pathways of the infection. It does not kill the fungi inside the infected hairs because, unlike the fungi, the fatty acids are unable to penetrate the hair shafts. However, the infected hairs are lost in the course of natural shedding, and the newly growing hair is no longer infected because all pathways have been sterilized. Thus a spontaneous cure takes place about two years after adolescence has set in, and thereafter the scalp is immune to this infection.—Stephen Rothman, M.D., Basic Research in Dermatology, *Bulletin of the Alumni Association, School of Medicine, University of Chicago,* Spring, 1959.

MODERN MANAGEMENT OF OBESITY—THE "SOCIAL DIET"

Milton Plotz, M.D., New York

One hundred consecutive, unselected patients with clinical obesity were classified as to the etiology of their condition. Overeating was accepted as the cause in 82, but in 18 cases this explanation was not satisfactory. The latter were mostly complicated cases of endocrine or metabolic disease. Satisfactory reduction (loss of 10% or more) of body weight was accomplished in 63 of the 82 and in 5 of the 18 by caloric restriction of diet. Simply reducing the portions of everything by about one-quarter enabled the patients to eat normally with inconspicuous modifications of the "social diet." Underlying emotional problems, if obvious to the practitioner, were treated by surface psychotherapy; if they were deep-seated, the patient was sent to a specialist. The author suggests medication with mild sedatives or anorectics as helpful during the period while new eating habits are being established.

Obesity has become an increasingly urgent health problem. The steady rise in the standard of living, including richer diets, mechanized transportation, audience rather than personal participation in sports, and automation, has helped to raise the number of calories taken in and lower the number of calories expended. The American population has for some time been growing sluggish and overfed, and only recently have there been signs of a swing in the other direction. Several fortunate circumstances have combined in the past decade or two to bring this problem sharply into focus and to lead to corrective action: overweight is now recognized as a threat to good health and long life, and the dictates of fashion have brought the slim figure back to popularity. Patients and nonpatients alike now seek advice about measures to control weight.

This has made the task of the physician somewhat easier. Experience has taught us that the most important factor in success in weight reduction is adequate motivation on the patient's part. If he is convinced that it is in his interest (health, appearance, or employment) to lose weight, he will usually make the necessary adjustments and even sacrifices. The factors already mentioned help establish this motivation, but the physician must reinforce these, keep encouraging his patient, and search out arguments applicable to individual cases.

For example, the physician will seek the reasons for the occurrence of obesity in the first place. One of the significant advances of the 20th century has been the demonstration (such as by Bruch[1] and others) of the importance of psychogenic mechanisms. The myth of the good-natured fat man has been finally exploded; he has been shown to have, more often than not, more than the average man's share of tensions and frustrations. It is now known that anxieties are more likely (except for short episodes) to result in nibbling than starvation and more likely to drive a man to food than to drink. In a short article, it is plainly impossible to list all the ways in which motivation may be established; it is enough to say that if a patient is convinced he should lose weight the specific problems of constructing a diet become relatively easy.

In making up a reducing plan for his patient, the physician must heed many factors or he will fail. Among these are the important sociological and cultural factors; for example, the national background must be reckoned with. If the patient or his parents are recent immigrants, plumpness may be valued for esthetic reasons or as evidence of successful emergence from poverty and hunger. It may be almost impossible to convince a foreign-born mother that heaviness is not a blessing or that tuberculosis does not invariably follow loss of weight. Ethnic factors in food selection must be recognized. An excellent article on the diet of Italian-Americans underscores this problem.[2]

Aside from personal and cultural food preferences, other factors must be taken into account.[3] The subject's basic requirements in fats, proteins, carbohydrates, minerals, and vitamins must be met, usually within the daily diet, although vitamin supplements are often necessary. The "satiety values" of food vary among themselves and from subject to subject. For example, meats are "satisfying" to most people, and I suspect that the success of bananas in many reducing diets, including the classic one of Harrop, is the result of its ability to "fill" the patient adequately. The "fetish value" of foods must be considered; in the popular mind, meat is sometimes equated with virility and spinach with the accumulation of "good, rich blood." This sort of prejudice will obtrude itself but seldom get in the way of establishing a sat-

isfactory dietary regimen. Exercise should be encouraged but should not be depended on for weight reduction without calorie restriction.

In a review of 100 consecutive, unselected cases of clinical obesity, a grouping has suggested itself without much difficulty:

Group 1—Obesity unassociated with overeating (18 cases). These were mostly complicated cases of endocrine or metabolic disease.

Group 2—Obesity associated with overeating (82 cases), subdivided into (*a*) those in whom motivation and cooperation were easily established (51), (*b*) those in whom motivation and cooperation were established only after initial resistance (17), and (*c*) those in whom motivation and/or cooperation were absent (14).

The results of treatment with dietary regimen to be described were as follows:

Group 1—5 of the 18 patients had satisfactory reduction (loss of 10% or more of body weight).

Group 2—49 of 51 patients in subgroup *a* had satisfactory reduction, 12 of 17 in subgroup *b* had satisfactory reduction, and 2 of 14 in subgroup *c* had satisfactory reduction.

It seems obvious that the dietary management of obesity is evolving today in much the same way as that of diabetes some 20 years ago. In the latter case, the use of highly artificial diets with special preparation—specially, sometimes exotically, prepared dietetic foods, mostly canned; and synthetic foods or food substitutes—has been superseded by diets as closely resembling the patient's former diet and those of his friends and family as possible. A similar evolution is taking place in the management of obesity, artificial and complicated regimens being replaced by those which throw less burden on his family and enable the patient to become a more acceptable member of society. Except among persons who are obsessed with concerns of health and diet, there are few things more of a nuisance to a host than to have a guest discuss his diet or to be forced into preparing separate dishes for him—only one's own diet is of real interest!

A few precautions must be taken. It is inadvisable to prescribe a reducing diet for a short time, such as a month or six weeks; prescribing a diet on a piecemeal basis leads eventually to disappointment or backsliding. The dieter should realize that he will have to change his habits for a long time; in some instances, the struggle against adiposity is a lifelong one. The arguments against excessive weight may be put strongly, but neither the words nor the attitude of the physician during the dieting period should be such as to suggest punishment or to result in guilt feelings. Reinforcement of good intentions and gentle prodding or praise are usually sufficient. Many of the emotional problems of obese persons are obvious to a general practitioner and will respond to surface psychotherapy; problems which seem to be more deep-seated, as evidenced by resistance or hostility, or which seem to involve complex family relationships should be avoided and the patient should be sent to a specialist.

The Social Diet

The patient is instructed to eat normally with only a few modifications when the "social diet" is used. Not more than one slice of bread is to be eaten at any meal. At breakfast, the patient may have cereal or one slice of toast—not both. A small portion of rice, noodles, cracked wheat, or spaghetti and a small baked potato or a portion of peas or lima beans at dinner will add variety to the lean meat, green vegetable routine. No gravies are to be added to foods. Portions of everything are to be reduced by about one-quarter. If possible, portions should be smaller than those previously taken, and "seconds" must not be taken. Desserts are to consist of one portion of fresh fruit, 1 oz. (28 Gm.) of cheese, or a small slice of angel food cake. Suitable supplementary reading may be recommended.[4] On this regimen, almost every determined patient will lose weight. In the New York City area, it was found in 100 successive patients that this resulted in a reduction of about 1,400 calories. In many instances, the patient's friends—and sometimes his family—did not know that he was on a diet.

In any case, when a new dietary regimen is prescribed for obesity or, for that matter, any other condition such as heart disease, diabetes, or hypertension, the dieter may need a medicament to help suppress his appetite. When newer eating habits are well established and accepted, the supportive medicine can often be withdrawn. In some instances, a mild sedative, such as phenobarbital or meprobamate, may suffice. More often, a stronger anorectic is needed; the drugs with which I have had most experience are the amphetamine series.

Anorectic agents of this type have been subjected to some adverse criticism recently, but studies by myself and careful double-blind experiments conducted by Fazekas and co-workers[5] have demonstrated that they have a genuine therapeutic action not to be explained by suggestion or placebo effect. Evidence which these authors review demonstrates that pronounced changes in satiety may be induced by lesions of the subcortical areas, particularly the hypothalamus. A reciprocal relationship may exist between the appetite-stimulating center and the appetite-inhibitory center, and changes in either of these may result in alterations of satiety.[6] The drugs may act on these areas by influencing localized neurohormonal activity.

1120 Church Ave., Brooklyn 18, N. Y.

The amphetamine combination used in this study was supplied as Obetrol by Obetrol Pharmaceutical, division of Rexar Pharmacal Corp., Brooklyn, N. Y.

This study was supported by a grant from the New Drug Institute.

SCOPE AND INTERPROFESSIONAL RELATIONS OF OCCUPATIONAL MEDICINE

B. Dixon Holland, M.D., Chicago

The subject of this paper is the scope of what occupational health encompasses or should encompass and what sort of relations obtain or should obtain between physicians engaged in this work and their confreres in the private practice of medicine. First, clarification should be made of the terms used to denote the several disciplines and activities involved in ministering to the health of the working man. The American Medical Association council is called the Council on Industrial Health. The principal specialty society of physicians serving industry is called the Industrial Medical Association. However, the specialty for which certification is now given qualified physicians by the American Board of Preventive Medicine is called occupational medicine rather than industrial medicine. Industrial nurses are beginning to call themselves occupational health nurses. Industrial hygienists, however, still cling to their title and have not yet called themselves occupational hygienists. "Occupational" is a broader term than "industrial" as the latter connotes industry, particularly manufacturing, whereas the former includes all "occupied" or employed persons, whatever the nature of their employment. We have to avoid, however, the extreme of having occupational health services cover all persons who "work" since, in the physiological sense, breathing is "work" and, *ipso facto,* the clientele of occupational health services could then be made to include all persons who breathe. Our confreres in private practice could not be blamed if at this point they rose up in righteous wrath.

Occupational health is preventive medicine in the working environment. The industrial physician gives attention to the healthfulness of the conditions and materials of the work and performs certain services; the latter embrace physical examinations, referral of patients to their family physicians when nonoccupational disease is found, health education and counseling, emergency or palliative treatment for certain nonoccupational conditions, immunization against diseases to which workers are occupationally exposed, and certain nonoccupational preventive health services. There must be free communication and mutual understanding between plant physician and family physician. In situations requiring mediation by a third party the county medical society's grievance committee should hear both sides. The problems and procedures of the industrial physician should be set forth at meetings under the auspices of state medical societies. Such presentations help to foster good relations between plant and family physicians.

The term "occupational" is really a better term than "industrial" as it refers to white-collar as well as blue-collar workers, persons employed in service, commercial, and business establishments as well as persons working in nuts and bolts factories, and farm and government workers as well as foundry workers. It follows, then, that "occupational health" is the proper term to denote those services carried

---

Secretary, Council on Industrial Health, American Medical Association.

Read before the Occupational Health Seminar, Chapel Hill, N. C., Feb. 6, 1959.

on for the protection and promotion of the health of employed personnel; "occupational medicine" properly denotes the physician's role therein and "occupational health nursing," the nurse's role. The industrial hygienist retains his same designation but has an area of coverage coextensive with that of the physician and nurse.

Scope of Occupational Health and of the Physician's Activities Therein

A publication entitled "Scope, Objectives and Functions of Occupational Health Programs" was prepared by the Council on Industrial Health two years ago, approved by the Board of Trustees, and adopted and promulgated by the House of Delegates of the American Medical Association as an official policy statement of the Association.

Health Protection and Promotion.—Occupational health is defined as essentially preventive medicine—health protection and promotion—in the working environment. It affords benefits to the personal health of the worker but only as a by-product, as it were. Occupational health properly includes (1) detecting, evaluating, and correcting hazards to health posed by the environment in which, and the materials with which, the employee works and (2) examining the employee medically at suitable intervals to place him at work he can perform efficiently and with safety to himself and others and discover promptly any health impairment attributable to his work. If, in the course of such occupational health examinations, health defects not attributable to work are found, and the worker, being apprised of them, has them cared for by his family physician, the worker realizes a personal health benefit, but only as a by-product.

Health Education and Counseling.—Health education and counseling are also properly included in an occupational health program.

Treatment.—Definitive treatment of nonoccupational illness and injury is not properly a function of occupational health programs. Palliative, nonrepetitive, or emergency treatment of any condition may properly be performed in an occupational health program. Definitive treatment of occupational illness and injury, while properly included in an occupational health program to the limits imposed by its personnel and facilities, is really not a part of occupational health, which is essentially a preventive medicine, health protection, and promotion service in the working environment.

Screening Procedures.—Procedures designed to uncover evidence of nonoccupational health impairments, such as degenerative, metabolic, and malignant diseases, are in considerable vogue, particularly multiphasic screening procedures applied to various groups of people, including employee groups. Strictly speaking, these do not fall within the scope delineated for occupational health programs in this American Medical Association publication on "Scope, Objectives and Functions of Occupational Health Programs." However, few medical societies would object to plant medical departments' performing such procedures on plant employees, particularly if employees who, through such procedures, showed evidence of possible nonoccupational health impairment were referred to their family physicians for definitive diagnosis or, at least, definitive treatment. In defense of plant medical departments' doing these procedures, someone is likely to cite the example of the secretary in a plant who was found, on cytological examination of a uterine cervical smear, to have cancer in a sufficiently early stage to permit successful treatment. The implication is—and possibly it is the correct one—that had she not been examined then and there, her cancer might not have been discovered until it was too advanced to be cured. Then there is posed mutely, if not voiced, the rhetorical question, admitting, of course, of only one answer: Would it have been better had she not been given this test? Until physical examinations or screening procedures of apparently well persons are practiced to a more desirable degree of consistency and regularity in physicians' offices and other community health facilities, it would seem callous to prohibit their performance by industrial medical departments. However, medical societies will have to address themselves to this problem, and it is hoped that they will find a solution agreeable to all concerned and in the best interests of the health of the people.

Immunization.—Immunization poses a comparable problem. To what extent is an industry justified, warranted, or beholden to offer its employees immunization procedures as part of its occupational health program? Certainly there can be no gainsaying that an industry should offer its employees available immunization procedures against such diseases as they are peculiarly exposed to by the materials with which and in the countries or places in which they have to work.

Many other criteria are advanced for guiding an industry in immunizing its employees. Some of the most liberal industrial physicians claim that any available immunization procedure whatsoever should be offered employees for the sake of their health. Others, while not going this far, hold that whenever a disease, even one not peculiar to the place or conditions of work, threatens a plant's output, the plant is warranted in offering its employees immunization procedures against this disease, if there are any. Others hold that the criterion should be not simply the threat of the output, per se, of a plant, company, or other establishment, but the curtailment or suspension of the delivery of services or goods vital to the health, safety, welfare, or economy of the public, such as food manufacturing and delivery, public health services, police and fire protection, water, gas, and electric services, and public transportation. Here, again, medical societies should come to grips with the problem, and it is hoped that they will find a solution satisfactory to all concerned. Such solution should recognize that the prevention as well as the detection and treatment of nonoccupational illness is primarily within the province of the private practice of medicine but that there are times and situations where the job to be done in immunization is so great, and the means wherewith and the time in which to do the job so limited, that all available hands must help.

"Courtesy" Services.—It seems to be a common practice for an industrial dispensary to perform, as a "courtesy" to private practitioners, various personal health services, particularly diagnostic, for those patients of these private practitioners who work in the plant. The physician is at some disadvantage when his patient comes to him and says, "I can get this blood test in the dispensary of the plant where I work, if you will give me a note to authorize it." The implication is that if the physician does not oblige he is denying his patient something which the patient has coming to him for nothing and which he possibly could get another physician to authorize. The physician, then, is likely to permit such services to be performed as a "courtesy" to him. Some medical societies, however, have inveighed against this practice, adducing various reasons. One has threatened with disciplinary action any of its members who accept from industrial dispensaries such services for their patients. Here, again, medical societies must find the solution to this problem, hopefully keeping all concerned happy.

Summary.—The scope of occupational health programs is seen, then, to embrace at any given time and in any given location so much of the following as local needs require and as the cognizant medical society approves: (1) attention to the healthfulness of the place, conditions, and materials of work and (2) such services for workers themselves as (*a*) preplacement and periodic physical examinations to insure their placement in work they can perform efficiently and with safety to themselves and others and to detect any health impairment they may sustain from their work; (*b*) referral to their family physicians for nonoccupational health conditions found; (*c*) health education and counseling; (*d*) treatment, largely emergency, palliative, and nonrepetitive, for nonoccupational conditions and treatment within the capabilities of the plant medical personnel and facilities for occupational conditions; (*e*) immunization against diseases to which they are occupationally exposed; and (*f*) such nonoccupational preventive health services—as immunization and multiphasic screening tests—as are currently in vogue in the community.

The physician is generally considered the captain of the team that carries out such programs. Other team members are the industrial hygienist or industrial hygiene engineer, who looks to the healthfulness of the work environment, and the industrial nurse or occupational health nurse, who acts for and under the direction of the physician, assisting him in the performance of physical examination procedures and other services on the person of the worker, imparting health education and counseling, maintaining records, and in many other ways running the dispensary.

Interprofessional Relations

Professional relations between physicians in occupational health and their confreres in private practice will be determined largely by the extent and effectiveness of the communications between the two groups and by the extent of their adherence, individually and collectively, to the golden rule. In short, the industrial physician has to get the attention of his confrere in private practice, and the latter has to give his attention, to the end that all physicians are acquainted with the proper scope, objectives, and functions of occupational health programs.

Application of the Golden Rule.—Physicians associated with occupational health programs must scrupulously keep within this proper scope and perform only proper functions at all times. In so adhering to the golden rule, the industrial physician can come with "clean hands" to his confrere in private practice and rightly expect him to reciprocate in kind, to cooperate with him in the many ways required to insure the success of the occupational health program. The private practitioner, for instance, it is hoped, would be more careful and conscientious in issuing to the plant's employees notes entitling them to sick leave and would recommend only so much sick leave as required for strictly health reasons. It is hoped that the plant physician and family physician would communicate freely with each other about the health of their employee-patient. It is hoped that they would exchange their physical and laboratory examination findings and their clinical impressions, even their recommendations for the round-the-clock, day-in-and-day-out management of the case. The employee-patient concerned would benefit enormously, far more than were his family physician and plant physician otherwise disposed.

The family physician, further reciprocating the plant physician's adherence to the golden rule, would avoid the altogether too common practice of ascribing to a patient's work environment, solely by the process of elimination, illness or symptoms for which no other cause is found. Rather, he would contact the plant physician, tell him of the nature of the employee-patient's illness and of the failure of examinations to discover the cause, and ask the plant physician whether anything in the work environment in the plant could possibly account for this illness. This would be in accord with the injunction that Bernardino Ramazzini, the 18th century "father of occupational medicine" gave physicians when he advocated that, in addition to the questions propounded by Hippocrates, physicians ask their patients one other, "What is your work?"

The family physician, meeting the plant physician halfway, would also refrain from giving to the employee-patient whom he discharges from his care to return to work such impractical advice as, for instance, to do "light" work. Rather, he would confer with the plant physician, acquaint him with the nature of the employee-patient's condition, and leave it up to the plant physician to recommend and medically supervise his proper placement at work in the plant.

Such cooperation between the plant physician and the family physician can stem only from good communications between them and from adherence by both to the golden rule. Benefits would accrue therefrom to the employee-patient in the form of better and more prompt attention to his health needs; to the plant in the form of increased production attending the improvement of employee health and morale and decreased sick absence and turnover; and to the physicians involved in the form of enhancement of their diagnostic acumen and therapeutic skill.

Keeping Programs Within Limits.—Of course the millennium has not arrived, and physicians, being human, will err and may not always forgive.

Some plant physicians do perform and do permit their industrial dispensaries to perform ostensibly occupational health services outside of what are set as proper limits in this official A. M. A. policy statement and outside of the limits set by their state and county medical societies. The private practitioners, seeing this, cannot be blamed if they complain, even retaliate in various ways, such as by withholding that Utopian cooperation just discussed. Plant physicians so transgressing should admit it and should then forthrightly either restrict their occupational health activities within the limits accepted by their county medical society or present to the county medical society grounds in defense of such of these services as do exceed these limits and ask that the limits be extended to cover them. Suppose the society renders a decision unfavorable to the plant physician in this situation. He should abide by it. However, if he chooses not to abide by it, he should so declare, rather than pretend to abide by it and then not do so. If the plant physician in this situation has the courage of his conviction that he is right in including in his occupational health program these services disapproved by his county medical society, he should set about winning the society over to his way of thinking in as friendly a manner as possible, not truculently or defiantly. He should not simply "draw his cloak about him" and sever relations with the society, with hurt feelings or in a smoldering, "ulcerogenic" rage.

The plant physician who, whether openly or covertly, continues to carry on ostensibly occupational health services beyond the limits prescribed or agreed to by his county medical society should prepare himself to pay, and prepare his company to pay, the price thereof. This price could be lack of cooperation, if not outright passive or active opposition, on the part of his confreres in private practice. This would indirectly and eventually exert a detrimental effect on the health and morale of the employees of the plant and on its sick absence, turnover, and production. The gains netted in return for this price might prove illusory and not worth the price in the long run if, indeed, in the "short run."

Communications.—Perhaps more frequent than actual transgressions are imagined or rumored transgressions of plant physicians. Not infrequently a family physician, extrapolating and generalizing from what he has heard, possibly from a patient of his who works in a plant, jumps to the conclusion that the plant's physician and dispensary personnel are performing, under the guise of their occupational health program, services outside the limits set or accepted by the county medical society. Possibly he does not speak about the matter to the plant physician concerned, simply behaves toward him as though the allegations were established. Not being acquainted with such allegations, the plant physician has no opportunity to refute them and state what he is actually doing. The family physician in this situation should, in all fairness to the plant physician, tell him what he has heard about his occupational health service and invite his comments, explanation, and clarification.

The plant physician behaves, at times, equally unfairly toward the family physician. The allegation is likely to be false or exaggerated which the plant physician hears to the effect that the family physician is aiding and abetting abuse of sick leave by a plant employee, that he is speaking disparagingly of the plant's occupational health program, or that he is interfering with the plant physician's exercise of his prerogative to guide medically the placement of an employee returning to work after an illness or injury. The plant physician, on hearing such an allegation, should, in adherence to the golden rule, seek a man-to-man talk with the family physician, tell him what he has heard about him, and invite his comments, explanation, and clarification.

Most physicians serving industry do so on a part-time or on-call basis and carry on a private practice also. I might digress to say that the vast majority of the employed population in the United States work in establishments too small to have a medical department of their own and that such services as they receive of the preventive medical sort described here must be at the hands of physicians in private practice in the community. Many physicians serving industry on a part-time or on-call basis and also carrying on a private practice are suspected of attracting, and many undoubtedly do attract, employees of the plants they serve into their offices as private patients, in a manner both unethical and unfair to their confreres in private practice. This is difficult to avoid. However, every physician connected with industry who practices privately should "bend over backward" to avoid committing and avoid even appearing to commit this offense. Here, certainly, adherence to the golden rule is advisable.

There is another way in which the plant physician may offend the private physician. Suppose the latter is taking care of a plant employee, either for a nonoccupational condition or, under workmen's compensation, for an occupational condition. Suppose that the plant physician believes that the attending physician is not treating the patient correctly or that he is performing unnecessary surgery, unduly prolonging hospitalization, requiring too many house or office calls, or charging excessive fees. Suppose the plant physician expresses such opinions to the employee-patient or to the plant management. When the attending physician hears of this, as he sooner or later will, somehow, he is likely to be hostile to the plant physician. The plant physician, instead of, or at least before, speaking critically of the attending physician to the employee-patient or plant management, should talk the matter over with the physician himself.

Grievances.—Sometimes, however, two individuals will conceive a mutual distrust and will fail to try, or will be unable, to reach a reconciliation. They may even refuse to talk with each other. Likewise, an individual may embark on and persist in a course of action which he believes right but which some of his peers believe wrong. In all such situations, there should be an impartial third party to hear both sides and give them its findings and recommendations. The county medical society's grievance committee should so function. It should afford any plant physician or family physician whose actions or utterances, actual or alleged, have given rise to a misunderstanding or estrangement ample opportunity to give an account of such actions or utterances and to explain and justify them. It is hoped that this committee will have the wisdom and the courage to render a decision calculated to serve best the interests of all concerned and of medicine. It is hoped that the society will press for, and the physicians involved will go along with, the implementation of this decision.

Summary

There is now a well-defined area of medical practice designated industrial or occupational medicine. Physicians engaged in such practice should conscientiously try to avoid encroaching into the domain of the private practitioner, just as the latter should recognize the prerogatives of the industrial physician and should meet him halfway in his offer to communicate and cooperate.

The county medical society should charge one of its committees, such as its grievance committee, to hear and amicably resolve, to the satisfaction and in the best interest of all concerned and of medicine, (1) any complaint to the effect that an industrial physician has failed to keep his program within limits accepted by the medical society and (2) any complaint to the effect that a private physician has usurped an industrial physician's prerogative or otherwise unfairly and unwarrantedly interfered with his program.

A seminar meeting in occupational health, held annually in every state, could prove invaluable in promoting occupational health and in establishing and maintaining good professional relations between physicians engaged in such work and their confreres in private practice.

ANGIOCARDIOGRAPHY.—Angiocardiography has come of age. It is an established and valuable procedure in the hands of a competent team in the diagnosis of congenital malformations of the heart and great vessels. A resurgence in its use has come about through a perfection of the technics for selective angiocardiography and retrograde aortography together with a marked mechanical improvement in high-speed biplane serial radiographic equipment and the development of safer contrast media. Angiocardiographic examinations, by establishing preoperative diagnoses, have made it possible to determine whether hypothermia or extracorporeal circulation will be more suitable for a particular case. Further advances in cine-angiography with image-intensifying equipment and the better viewing afforded by the Spectroscope offer even greater possibilities for more effective use of this procedure.—W. G. Scott, M.D., and B. S. Loitman, M.D., Angiocardiography in Diagnosing Congenital Malformations of the Heart and the Great Vessels, *Postgraduate Medicine*, May, 1959.

FLOW SHEET FOR USE IN OBSTETRIC COAGULATION PROBLEMS

James C. Caillouette, M.D., Laurence D. Longo, M.D.
and
Keith P. Russell, M.D., Los Angeles

Success in preventing and treating hemorrhage in obstetric patients depends on the development of a systematic procedure which precludes the possibility of omissions and oversights. The danger of coagulation defects must be kept constantly in mind. The plan here outlined includes four tests designed to reveal such defects. If any exist, blood must be obtained for typing and crossmatching in preparation for transfusions of whole blood. Three procedures are outlined for treating patients whose blood is deficient in fibrinogen, contains a heparin-like factor, or manifests fibrinolytic activity. The primary aims are early diagnosis and prompt treatment.

The problem of managing acute hemorrhage in the obstetric patient presents a challenge to every obstetrician. Proper diagnosis and adequate treatment demand an orderly and rapid sequence of procedures. Current reports in the literature stress the occurrence of coagulation defects in antepartum, intrapartum, and postpartum hemorrhage. The incidence of a coagulation defect has been found to be as high as 1 per 1,000 live births in a recent series.[1] It is the purpose of this communication to present a flow sheet which has been developed at the Los Angeles County Hospital for following the course of such patients. This record, shown in the figure and table, has been most helpful in the management of acute hemorrhage complicating pregnancy.

Diagnosis

Since the primary aims are early diagnosis and prompt treatment, the importance of a high index of suspicion cannot be overemphasized. The physician who infrequently practices obstetrics may be unfamiliar with some of the bedside procedures in the diagnosis and management of coagulation defects associated with pregnancy. These bedside procedures have been outlined in detail in previous articles.[2] In brief, they are the clot observation test, qualitative fibrinogen estimation, and the determination of circulating heparin-like factor or fibrinolysin level.

The clot observation test appears essential in all cases of suspected abruptio placentae, postpartum bleeding which does not respond to the usual pro-

Flow Sheet for Hemorrhage, Abruptio Placentae, Coagulation Defect, and Other Disorders (Reverse Side)

Clot Observation Test.—Five-milliliter sample of maternal blood, in 15-ml. test tube. Gently agitate four or five times. In our experience at this hospital the clotting mechanism is defective if there is no clot within six minutes or if a clot forms which is not solid and lyses within one hour. In other hospitals with other equipment the maximum normal time of clotting may be longer.

Size: After clot retraction a normal clot should occupy 35 to 45% of the total volume of the blood specimen.

Stability: Allow clot to stand one-half hour, then shake test tube a few times. A normal clot will withstand this procedure without breaking.

Bedside Qualitative Fibrinogen Estimation Based on Clot Observation Test.—Clotting time less than 6 minutes: fibrinogen level probably greater than 150 mg.%.

Clotting time more than 6 minutes, with poor clot: fibrinogen level probably 100 to 150 mg.%.

No clot in 30 minutes: fibrinogen level probably less than 100 mg.%.

Bedside Determination of Heparin-like Factor.—Five milliliters of unclotted maternal blood plus 5 ml. of normal control blood. Failure of the combined specimen to clot indicates the presence of a heparin-like factor.

Bedside Determination of Circulating Fibrinolysin.—Five milliliters of unclotted maternal blood plus 5 ml. of clotted normal control blood is held at room temperature. Lysis of the normal clot within one hour indicates the presence of fibrinolysin.

Fibrinogen Replacement.—Four grams of fibrinogen must be given at a rapid rate to the patient with little or no circulation fibrinogen, to elevate the serum fibrinogen above the critical level of 100 mg.%. If the clotting defect is not significantly improved within one hour, an additional 4 Gm. of fibrinogen should be given. Termination of the pregnancy should be expedited.

Treatment of Heparin-like Factor.—Dosage of protamine sulfate: 20 to 50 mg. intravenously. This should be given very slowly and should not be repeated unless persistence of the heparin-like factor can be subsequently demonstrated.

Treatment of Fibrinolysin.—Dosage of hydrocortisone: An initial intravenous dose of 200 mg. should be given, followed by 100 mg. every four hours during the first 24 hours. Following this the dose can be decreased 100 mg. per day, and the intramuscular route can be used.

Height of Fundus.—Measure with calipers in centimeters from symphysis pubis.

From the Department of Obstetrics and Gynecology, Los Angeles County Hospital, and the University of Southern California School of Medicine.

cedures of uterine massage, oxytocics, and repair of lacerations, intrauterine fetal death, and profound shock suggestive of amniotic fluid embolism. In essence, the diagnosis of fibrinogen deficiency, heparin-like factor or fibrinolysis must be suspected in every case of hemorrhage of undetermined etiology.

Management

Once the diagnosis of a coagulation defect has been established, proper management must be instituted immediately. In the absence of a well-organized course of procedure, the most routine measures may be inadvertently overlooked. The steps which should be taken in rapid sequence are

to (1) obtain blood for typing and crossmatching, (2) administer whole blood in amounts sufficient to replace the estimated blood loss, with general antishock measures, (3) give fibrinogen intravenously, when indicated, until the blood clot is stable, (4) institute antiheparin or antifibrinolysin therapy as indicated, and (5) expedite delivery.

Summary

The most important single point in the diagnosis of a coagulation defect in pregnancy is a high index of suspicion. A flow sheet has been found useful in the diagnosis and management of this problem.

511 S. Bonnie Brae St. (57) (Dr. Russell).

Printed copies of the flow sheet may be obtained from Cutter Laboratories, Berkeley 4, Calif.

OBSERVATIONS ON ONE HUNDRED CASES OF CEREBRAL ANGIOMA

Fuad Sabra, M.D., Beirut, Lebanon

In recent years there has been a revival of interest in the surgical treatment of cerebral angiomatous malformations.[1] In part, this is due to the widespread use of cerebral angiography which allows for more precise definition of this lesion in regard to size, location, and source of blood supply. In addition, the application of hypothermic and hypotensive techniques to neurosurgery has markedly reduced the hazards of uncontrolled hemorrhage during operation. Despite these advances, the operation is not without risk, as it may result in irreversible neurological deficit, such as aphasia, hemiplegia, or other focal neurological defects. It seems appropriate, therefore, that a review of the symptoms and natural history of this disease be undertaken to afford a background for assessing the value of operative intervention.

Various aspects of cerebral angiomas have appeared in the literature.[2] This report deals with the clinical, electroencephalographic, pneumographic, and roentgenographic findings. In a future communication, I shall report on the longevity of patients with such lesions, the natural history of the disease, and the comparative results of surgical and conservative treatment.

Cushing and Bailey[2a] divide all the cerebral vascular abnormalities into two groups: (1) the true neoplasms or hemangioblastomas and (2) the cerebral vascular malformations. The latter group, which is the subject of this paper, is divided into three forms: telangiectases, venous angiomas, and arterial angiomas (arteriovenous aneurysms).

Symptoms that should alert the clinician to consider diagnosis of cerebral angioma include focal convulsive seizures in patients under 30 years of age, evidence of subarachnoid hemorrhage, cranial bruit, linear streaks of calcification in x-ray films of the skull, and recurrent hemicrania. The patients in this series were proved to have a true angiomatous malformation by cerebral angiography, intracerebral operation, or autopsy. Of the 100 patients, 52 were females and 48 males.

These cerebral vascular malformations are assumed to result from defective development of the primitive vascular plexus.[3] Such angiomas may be very small and located on the surface of the brain. They may also be huge, in the form of a solid triangle with the base on the surface of the brain and the apex deep in the cerebrum near the ventricular system.

Case Material

The patients included in this study were proved to have a true angiomatous malformation by one of the following methods: cerebral angiography, intracerebral operation, or autopsy. Patients studied were admitted to either the Neurological Institute of New York or the American University Hospital in Beirut, Lebanon.

Associate Professor of Neurology, American University of Beirut.

Of the 100 patients studied, 52 were females and 48 males. Their ages ranged from 3 months to 63 years. The average age at which the first symptoms occurred was 28 years. The patients were evaluated for the following major clinical characteristics of the disease: convulsive seizures; subarachnoid hemorrhage, with or without focal neurological signs; headache; cranial bruit; linear calcification seen in x-ray films of the skull; electroencephalographic abnormalities; pneumoencephalographic abnormalities; changes in the cardiovascular dynamics; and abnormalities of the peripheral blood cell count.

Results

Convulsive Seizures.—Seventy patients suffered from convulsive seizures; 50 of them had focal seizures and 20 had generalized attacks without aura. The lesions in the patients who had generalized convulsions without aura were usually located in either the temporal or the frontal lobes. In almost all the 50 patients who suffered from focal seizures, the aura was of localizing value. In fact it was a more accurate index to the location of the lesion than the electroencephalographic study.

Forty-eight of the 70 patients who suffered from convulsive seizures received anticonvulsant medication regularly. In 25 patients the attacks were completely controlled; in 14 the seizures were reduced in frequency; and in 9 there was no change in the seizures. One patient developed attacks of status epilepticus after surgical removal of an angioma. The intravenous administration of thiopental (Pentothal) sodium was effective in controlling these attacks.

Hemorrhage.—Intracranial hemorrhage, the most serious complication of cerebral angiomas, occurred in 45 patients. Bleeding into the subarachnoid space was present in all 45 patients. In 21 patients there was simultaneous subarachnoid and intracerebral hemorrhage. Three patients had three episodes of hemorrhage, 21 had two, and 21 had only one.

Headaches.—Forty patients had recurrent headaches. Headaches which developed at the time of subarachnoid or intracerebral hemorrhage or after a convulsive seizure were excluded from this analysis. In 20 patients the headaches were preceded or accompanied by visual phenomena simulating those of migraine. Of the 20 who had migraine-like headaches, 5 suffered from diplopia during the attack of headache. Hemicrania, when present, was always on the side of the angioma.

Cranial Bruit.—Twenty-five of the 100 patients had an audible bruit. This was most commonly found over the eyeballs or mastoids. In five of the patients with an audible bruit, the arteriovenous malformation was fed by the external carotid artery.

Blood Pressure, Heart Size, and Heart Murmurs.—Ninety-nine patients had normal blood pressure. In one patient the pressure was 160/100 mm. Hg. Enlargement of the heart shadow in x-ray films of the chest was not found in any of the patients. This is in contrast to the report of Brock and Dyke,[4] who found enlargement of the heart in four of eight patients. Low diastolic pressures have been reported by Shenkin and associates.[5] This was present in one patient in the present series. None of the 100 patients had polycythemia.

X-rays of the Skull.—Intracerebral calcifications, in the form of circular or parallel streaks, were present in 20 patients. In four there was widening of the sella turcica and osteoporosis of the dorsum sellae. In 15 patients the vascular channels in the cranium overlying the arteriovenous aneurysm were enlarged.

Electroencephalographic Studies.—The electroencephalogram showed abnormal findings in 56 patients (to compare, see study by Groethuysen and associates [6]). Correct lateralization of the lesion was obtained in 42 patients, all of whom had convulsive seizures. In the remaining 14 there were no focal abnormalities. Of the 21 patients who had intracerebral hemorrhage, 18 developed convulsive seizures, and all of these had electroencephalographic changes on the side of the lesion.

Pneumographic Studies. — Pneumoencephalography or ventriculography was performed in 28 cases because the symptoms and signs suggested an expanding intracranial mass. Reports in the literature indicate that the usual finding in the pneumoencephalogram is localized or generalized atrophy of one hemisphere. Occasionally, there is shifting of the intracranial contents plus atrophy of the brain of the side of the shifted ventricle.[21] Fifteen of the patients in the present study, however, showed pneumoencephalographic changes characteristic of an expanding mass without atrophy. Angiography was performed in four of these patients, and the arteriovenous aneurysm was, of course, clearly demonstrated. The other 11 patients were subjected to craniotomy, with the preoperative diagnosis of brain tumor. Eleven patients showed local atrophy at the site of the arteriovenous aneurysm. Two showed generalized atrophy of the cerebrum and cerebellum; these two patients had large arteriovenous aneurysms. The malformation apparently produced a large shunt, and the atrophy of the cerebrum and cerebellum was explained on basis of decreased blood supply to these areas of the brain.

Summary and Conclusions

In 100 patients suffering from cerebral angioma, the lesion was confirmed by angiography, operation, or autopsy. The onset of symptoms was in the third decade of life in the majority of cases. Symptoms indicative of intracerebral hemorrhage occurred in 45 patients.

Twenty patients suffered from migraine-like headaches. The headache, when hemicranial, was always on the side of the lesion. Convulsive seizures occurred in 70 patients. These were focal in nature in 50. The aura was of more value in localization of the lesion than the electroencephalogram. About two-thirds of the patients suffering from seizures responded well to anticonvulsant medication. Twenty-five of the patients had an audible bruit.

None of the patients had polycythemia, enlargement of the heart, or cardiac murmurs. Only one patient had a low diastolic pressure.

The electroencephalogram was useful in lateralization of the lesion in the 42 patients who suffered from focal seizures. Linear streaks of calcification were present in the x-ray films of the skull in 20 patients. Findings indicative of expanding intracranial lesions were present in the pneumoencephalograms of 15 patients, and focal or generalized cortical atrophy was present in 11. The lesion was clearly demonstrated by angiography in all patients in whom these tests were performed.

The following group of symptoms should alert the clinician to consider the diagnosis of a cerebral angioma: recurrent hemicrania, always localized to one side of the head; the occurrence of focal convulsive seizures in patients under 30 years of age; evidence of subarachnoid hemorrhage, with or without focal neurological signs; cranial bruit; and linear streaks of calcification in the x-ray films of the skull. The diagnosis can be confirmed by angiography.

Professors H. Houston Merritt and J. Lawrence Pool and colleagues at the American University Hospital of Beirut gave permission to use case records of their patients. Dr. Melvin D. Yahr, Neurological Institute of New York, aided in study of these cases.

WHO CAN TRAVEL SAFELY BY JET PLANE?—Air travel per se, and particularly jet air travel, does not present a hazard to patients who are transportable. However, owing to a lack of medical facilities and trained medical personnel aboard commercial aircraft and in consideration of the comfort of fellow passengers, certain restrictions are necessary:

A patient whose illness is objectionable to other passengers because of appearance or odor should not be permitted to travel on commercial aircraft. Patients with contagious diseases should not be carried for obvious reasons. A patient who, because of his illness, cannot take care of his needs should not be carried unless, by previous arrangements, a suitable medical attendant travels with him. Cabin attendants are usually too busy with routine duties to provide anything but simple emergency first aid care to an individual passenger. Patients whose behavior might be upsetting or hazardous to fellow passengers should not be carried. This applies primarily to patients with severe emotional disturbances. Patients with illness of a type or severity to present a serious hazard in a mild respiratory stress situation when expert medical care is not immediately available should not fly on commercial aircraft. Illnesses associated with trapped gases in body cavities, such as pneumothorax, should not fly because of gas expansion at altitude.

Problem cases should be evaluated for flight by the private physician on an individual basis. As an example, since there are no adequate facilities to perform a delivery in the air, a woman beyond the eighth month of pregnancy should not fly. Air travel is not injurious to an expectant mother or the unborn child, but a delivery in anything but medical environment can cause unnecessary problems. . . .

Airline medical directors are available for consultation, with the personal physician, on cases presenting special or difficult problems in relation to air travel.—M. Frederick Leeds, M.D., Medical Aspects of Commercial Jet Air Travel, *California Medicine,* April, 1959.

STEROID TREATMENT OF LYE BURNS OF THE ESOPHAGUS

Charles L. Miller, M.D.
and
Robert O. Y. Warren, M.D., Wilmington, Del.

The effectiveness of cortisone in preventing esophageal stenosis after ingestion of lye in rabbits suggested the use of steroids for the prevention of stenosis in children who have swallowed lye. Prednisone was administered to 13 children who had swallowed lye. The data are summarized. In three cases which are described in detail the lye was strong enough to cause visible lesions in the mouth. The dosage of prednisone was 10 mg. each six or eight hours for periods up to 16 days, with tetracycline to prevent infection. Neither infection nor stricture appeared in any of the 13 children. Although the treatment with steroids appeared to be effective, the real answer lies in the prevention of accidents with lye.

The frequent ingestion by children of substances containing lye and the frequent occurrence of esophageal strictures and stenosis as a result make the treatment of this ingestion important. The addition of steroid therapy to the management of this problem has greatly altered the prognosis, and for this reason we wish to present our results with 13 children so treated.

A survey in 1957 showed lye to be the fifth leading cause of poisoning in patients under the age of 19 years.[1] It is mentioned especially frequently as an important problem in the 1-to-4-year age group. Prior to the introduction of steroids, it was estimated by various authors that from 56 to 70% of those ingesting lye developed esophageal strictures.[2] Hanckel,[3] in 1951, described the pathological physiology which occurs. The immediate reaction is one of inflammation and edema, causing dysphagia which disappears in two or three days as the swelling subsides. This is followed by a period of normal swallowing until scar tissue gradually forms, and obstruction of the esophagus occurs in two to three weeks after the initial burn. Difficulty in swallowing solids appears first, then difficulty in swallowing liquids, with complete stenosis in 50 to 60% of cases. Untreated, all of these patients will die from dehydration and starvation. Treatment until recently has consisted of bougienage, either blind or visually with the aid of an esophagoscope, or surgical resection. A 25-year survey done in 1956 encompassed cases of 233 patients; 206 had severe esophagitis, 188 responded to repeated bougienage, 14 required resection, and 5 died from perforation of the esophagus.[2b]

Rosenberg and associates,[4] in 1951, undertook the use of cortisone in experimentally produced sodium hydroxide burns of the esophagus in rabbits and found that, while 7 of 8 controls developed severe strictures, only 1 of 17 treated with cortisone developed a mild stricture. However, 10 of the 17 died of infection, predominantly mediastinitis. In a repeat study,[5] in 1953, the same group added penicillin to the treatment and found that only 3 of 21 rabbits so treated died (2 from diarrhea, 1 from pneumonia) and only 1 developed a stricture.

Weisskopf,[6] in 1952, treated a 17-month-old boy who ingested lye with cortisone and oxytetracycline (Terramycin) therapy with a good result. He then produced lye burns in seven dogs which he treated with cortisone and oxytetracycline for from 7 to 120 days. No strictures resulted, but one died from pneumonia; strictures developed in seven of eight controls. This work prompted the use of steroids in children who accidentally ingested lye-containing products. The first report of any magnitude was that of Ray and Morgan,[7] in 1956, who reported 10 patients treated with cortisone and antibiotics in whom no strictures developed and one patient in whom treatment was begun four days after ingestion and in whom a stricture developed after three months. Cleveland and associates,[8] in 1958, reported a similar program, with slightly less good results. Three of 14 whom they treated developed strictures, and 2 of 4 who had less than optimum treatment also developed strictures.

We have been using steroids and antibiotics in the treatment of lye ingestion for over two years. Since our results to date have been uniformly good, we wish to outline the regimen used and comment somewhat about it.

Treatment and Results

A total of 13 children have been treated with prednisone (Meticorten) and antibiotics, all but one in the past two years. At the beginning the dosage schedule was not definitely established, and there was some variation in the length of treatment, depending on the judgment of the attending staff, severity of the burn, and findings at esophagoscopy. However, for the past year the procedure

---

Resident in Pediatrics (Dr. Miller) and Director, Department of Pediatrics (Dr. Warren), Delaware Hospital.

has been standardized, and the last 11 patients were treated similarly, with the exception of the patient in case 7, who ingested a preparation containing only 4.5% sodium hydroxide and who did not have esophagoscopy. The other 12 patients ingested a concentrated sodium hydroxide preparation.

On admission all patients had a nasogastric tube inserted for feeding purposes, which was removed after three days. Two patients pulled out their tubes within 24 hours, and they were not reinserted. Clear liquids, progressing to a soft diet in three days, were given. A chest x-ray and tuberculin test were done on the day of admission, and therapy with prednisone was started with approximately 1 mg. per pound of body weight per 24 hours, divided into three or four daily oral doses. Tetracycline was given in a dosage of 15 to 20 mg. per pound per day orally. Esophagoscopy was done 7 to 10 days after admission; if no burn was noted, treatment with steroids was tapered off over the next few days, and tetracycline was withdrawn one day after steroid therapy was discontinued. If a burn was found in the esophagus, therapy with prednisone was continued for another week and a "barium swallow" performed. If no stricture was noted on the "barium swallow" (and none was), treatment with prednisone was then tapered off at a slower rate over the next two to three weeks and stopped. Blood pressures were checked daily and frequent urinalyses for sugar were performed; no complications were noted. No supplemental potassium was given, and there was no restriction of salt intake.

*Data on Thirteen Patients Treated for Lye Burns of the Esophagus**

Case	Age, Mo.	Days of Intensive Prednisone Dosage	Esophagoscopy Results	Follow-up, Mo.
1..............	18	6	Not done	42
2..............	36	9	Not done	24
3..............	14	13	Hyperemia and edema	12
4..............	8	12	Hyperemia	12
5..............	30	13	Hyperemia and ulceration	12
6..............	30	10	Hyperemia and edema	11
7..............	20	6	Not done	8
8..............	36	15	Hyperemia and edema	5
9..............	36	13	Hyperemia	4
10..............	24	14	Hyperemia and edema	3
11..............	30	16	Granulations and bleeding	3
12..............	24	10	Normal	2
13..............	18	16	Hyperemia and edema	1

* Results of "barium swallow" were normal in all cases except 1 and 7, in which cases study was not done.

There were no strictures in any of the 13 patients so treated, and there were no complicating infections. All children were asymptomatic within three days after admission and remained so. Esophagoscopy was performed in all but the first two patients and the seventh, who ingested a dilute lye preparation. In all but one there was evidence of burn in the esophagus, either hyperemia and edema or ulceration. A "barium swallow" was performed in 11 patients at about two to three weeks after ingestion and was normal in each instance. Follow-up varied from one month to three and one-half years, and no subsequent strictures have developed. A summary of the cases is presented in the accompanying table. Three representative cases are described in more detail.

Report of Cases

CASE 3.—A 14-month-old girl was admitted to the Delaware Hospital on Dec. 20, 1957, with a history of having ingested an unknown amount of a concentrated lye preparation just prior to admission. Physical examination revealed a well-developed child, weighing 18 lb. (8,164 Gm.), and in no apparent distress. Her lips were swollen, and burns were seen in the inside of her mouth, with partial denudation of her tongue. No other abnormalities were noted. Routine blood cell count revealed a hemoglobin level of 9.3 Gm. per 100 cc. and a hematocrit of 33%; white blood cell count and differential were within normal limits, as was the urinalysis. A tuberculin test was negative, and her chest x-ray was reported as showing normal heart and lungs. A nasogastric tube was passed immediately after admission, and through it she was fed a diet of food prepared in a "blendor" until Dec. 28, when it was removed and a soft diet given. She was given therapy with prednisone, 15 mg. for the first dose and then 10 mg. every eight hours, and tetracycline, 150 mg. for the first dose and then 100 mg. every eight hours. On Dec. 28 esophagoscopy was carried out with the patient under general anesthesia, and marked hyperemia and edema were seen in the proximal portion of the esophagus and also in its distal portion. Prednisone therapy was continued in the same dosage until Jan. 2, 1958, after which it was reduced stepwise over the next week and withdrawn on Jan. 8. Tetracycline therapy was continued until three days after her discharge on Jan. 8. A "barium swallow" was performed on the day of discharge and was normal. The child has been asymptomatic for over a year.

CASE 10.—A 24-month-old girl was admitted to the Delaware Hospital on Dec. 2, 1958, with a history of ingestion of an unknown quantity of a concentrated lye preparation about 45 minutes prior to admission. She vomited immediately after swallowing the lye. Initial physical examination revealed a well-developed child, weighing 28 lb. (12.7 kg.), and in no apparent distress. Her tongue was desquamated over an area of about 1 in. in diameter; no other evidence of burn was noted, and the remainder of her examination was within normal limits. Blood cell count was normal; urinalysis revealed 1+ albumin, 4+ acetone, and 8-10 white blood cells per high-power field on admission, but was normal when repeated. A tuberculin test was negative, and a chest x-ray was reported as showing normal heart and lungs. A nasogastric tube was inserted on admission and a full liquid diet was begun; however, she pulled out her tube after about 36 hours and it was not reinserted. She tolerated orally given fluids well, and she was given a soft diet on Dec. 5. Prednisone, 10 mg., and tetracycline, 125 mg., were given every six hours. On Dec. 12 esophagoscopy was carried out with the patient under general anesthesia, and the esophagus appeared normal. The dosage of prednisone was then tapered off over the next week. She was discharged on Dec. 19, still on therapy with 5 mg. of prednisone every eight hours, and this was reduced gradually and stopped on Jan. 7, 1959, at which time the tetracycline therapy was also discontinued. She has had no symptoms since.

CASE 13.—An 18-month-old boy was admitted to the Delaware Hospital on Jan. 7, 1959, with a history of ingestion of a concentrated lye preparation from a bottle approximately two hours prior to admission. He vomited immediately after the ingestion. Physical examination revealed a well-developed boy, weighing 27 lb. (12.2 kg.), and in no apparent distress. Denuded areas were present on his lips, gums, tongue, and posterior pharynx, but no other abnormalities were noted. On admission, blood cell count and urinalysis were within normal limits; tuberculin tests were negative; and a chest x-ray was reported as showing normal heart and lungs. A nasogastric tube was inserted on admission, through which a full liquid diet was given for three days. At the end of this time the tube was removed and a soft diet given, which he tolerated well. Prednisone, 10 mg. every eight hours, and tetracycline, 100 mg. every six hours, were given. On Jan. 16 esophagoscopy was carried out with the patient under general anesthesia and two areas of hyperemia and edema were noted—one at about the level of the arch of the aorta and one at the level of the diaphragm. Therapy with prednisone was continued until Jan. 23, after which the dosage was tapered gradually and discontinued on Feb. 2, at which time the tetracycline therapy was also stopped. A "barium swallow" was performed on Jan. 27 and was normal. The child was discharged on Feb. 2, 1959, and has remained asymptomatic.

Comment

While the optimum dosage schedule and the length of treatment is yet to be definitely determined, we feel that our regimen as outlined is quite adequate. Although most of our patients showed signs of adrenal cortical hyperfunction, we have had no serious complications. It was originally felt that tube feedings should be given for the first three days, the period of initial inflammation and edema; but we are now wondering whether there might not be less trauma associated with swallowing clear liquids than with the continued irritation of a foreign body such as a nasogastric tube. Passing the tube initially is also not without danger, and, despite the fact that we have had no difficulty so far, we are contemplating the elimination of the tube in our treatment. Swallowing a string has been suggested,[7] but since there is little likelihood of complete esophageal stenosis in patients treated adequately with cortisone, this is probably also an unnecessary procedure. Our two patients who removed their tubes before the initial three days passed swallowed clear liquids easily, and we have given sips of liquids to others, while their tubes were in place, with no difficulty. All patients have tolerated a soft diet well after the third day, and this should be continued until after three weeks, when a general diet can be given.

Despite the fact that the more severe consequences of lye ingestion can be averted with proper and early treatment in most cases, it is still a serious problem. The real answer lies in the field of prevention, especially through dissemination to the public of information about the dangers inherent in leaving poisonous substances within the reach of children.

Summary

Stricture of the esophagus after the ingestion of lye can be prevented in most instances. In the past two years we have found treatment with steroids and antibiotics to be successful in 13 children who ingested lye.

SIMPLE PAPER TEST FOR DETERMINING BACTERIAL SENSITIVITY TO ANTIBIOTICS

Wayne L. Ryan, Ph.D., Howard J. Igel, B.S.
and
Perry T. Williams, M.D., Omaha

The test paper here described makes it relatively easy to choose the antibiotic best suited for treatment of a given bacterial infection. Each type of test paper bears both a culture medium and an antibiotic and is supplied, dry and sterile, in a transparent envelope. For a given test, the paper is wetted and inoculated and the envelope with its contents is incubated. It is not necessary to wait for the appearance of visible colonies because the metabolic activity of the bacteria is detected by an indicator (triphenyltetrazolium chloride) which is colorless until reduced to a bright red dye by bacterial enzymes. The reliability of the new test was established by a comparative study with other methods in 100 clinical cases. The test paper is easily stored, and the entire unit can be incinerated after use. It is therefore useful in general office practice and should help to make sure that each patient receives the most effective antibiotic.

Since the advent of antibiotics concerted effort has been made to devise tests for determining microbial susceptibility to specific antibiotics which could be used by clinicians as a reliable guide in selecting the most effective antibiotic for use in bacterial infections. Although the tube dilution and agar plate–antibiotic disk techniques have become standard tests in hospital laboratories, they have not been widely used in the physician's office. There are many reasons for clinicians not adopting these techniques in office practice, but probably the most important are that the tests are too cumbersome, time-consuming, and relatively expensive.

The object of this investigation was to develop a colorimetric paper test which would be easy to read, accurate, convenient, and stable. If these criteria were met the test could be used routinely in office practice, where the majority of patients with infections are treated.

It became apparent that to achieve these objectives the test paper would have to incorporate all ingredients necessary for all sensitivity testing, that is, both the culture medium and the antibiotics. In addition, since visualization of bacteria on paper is impossible, the test paper would also have to contain an indicator of bacterial activity or growth. Many indicator systems[1] were studied but only the indicator triphenyltetrazolium chloride was found satisfactory. This indicator is colorless in its oxidized form and bright red in its reduced form. It is reduced to the red triphenylformazan by a large number of bacterial enzymes. Under the conditions employed in the test, all bacteria reduced the indicator to a bright red color.

Schleicher and Schuell no. 470 filter paper was impregnated with tryptose phosphate broth containing 0.01% triphenyltetrazolium chloride. The paper was dried at 50 C. Numerous designs of filter paper were tested and found to be satisfactory but no unique advantage could be attributed to any of the designs. The test paper design shown in the figure seemed to provide zones of bacterial inhibition which could be read with maximum ease and clarity. The various antibiotics were pipetted onto the tips of the projections. After inoculation and incubation all areas where bacterial growth occurred were bright red. Areas in which inhibition occurred remained white.

The amount of antibiotic used on the projections was determined in two ways. First the concentration of antibiotic in micrograms per milliliter was determined by calculating the volume of hydrated medium contained in each projection. This determination was used in adjusting the concentration of antibiotics to correspond to the blood level of the antibiotic attainable. Then the test was compared with tube dilution studies on 43 different organisms. Some of the results of this study are shown in table 1.

The procedure used with the test papers was quite simple. After removal from a sealed plastic sack with sterile forceps the test paper was moistened by floating it on the surface of tap water for a few seconds. The test paper was then returned to the plastic sack and the surface of the paper swabbed with the infectious material. Scotch tape was used to seal the cut edge of the plastic sack and the unit was then incubated at 37 C.

Assistant Professor of Biochemistry (Dr. Ryan), medical student (Mr. Igel), and Instructor in Medicine (Dr. Williams), Creighton University School of Medicine.

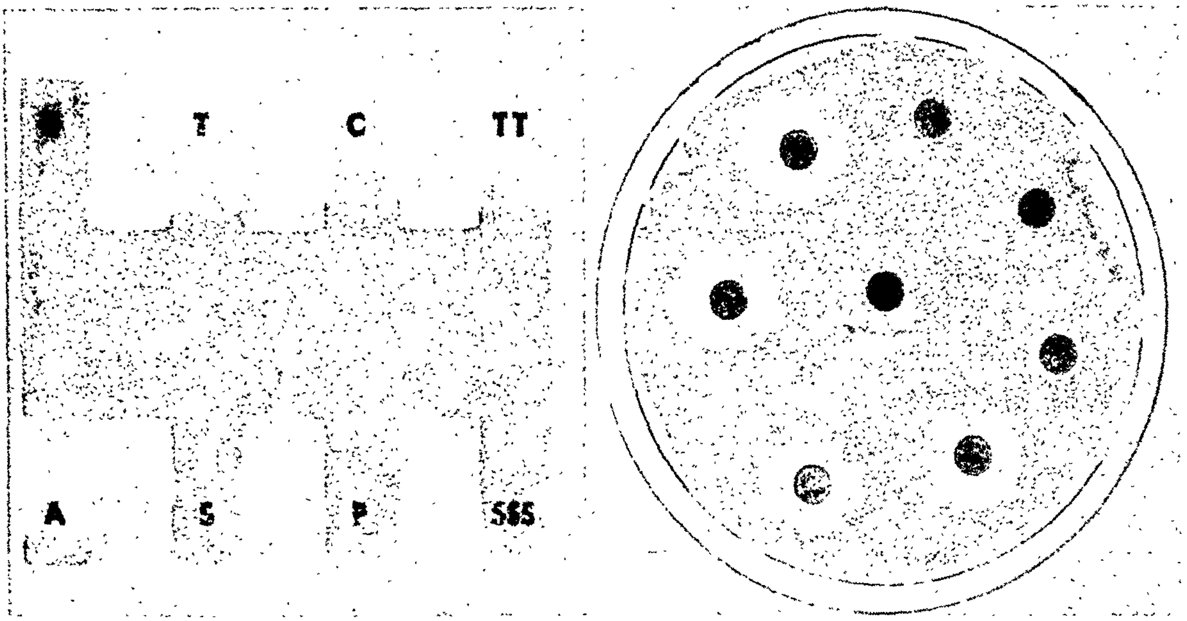
Although the use of tap water in the procedure would seem to destroy the validity of the test, it was found in sterility studies with 200 uninoculated test papers that only 6 of them became contaminated from use of the above procedure. The contamination occurred on the back of the test paper and consequently would not have interfered with the results, since readings are made on the front or printed side. The time required for completion of the test was found to depend on the number of organisms in the specimen used for inoculation. In the studies presented here all tests were completed in from 3 to 12 hours.

Clinical Studies

The clinical application of the paper culture test was studied in 100 unselected frank or suspected bacterial infections encountered in normal office practice (table 2). In 15 of the 100 cases the disk-agar test was run simultaneously. Infections in patients from whom cultures were made included boils, tonsillitis, abscesses, pharyngitis, sinusitis, infectious enteritis, urinary tract infections, felons, otitis, and folliculitis. In 76 cases antibiotic therapy was initiated empirically according to clinical judgment and experience before the results of the sensitivity test were available. Medication in the remaining 24 cases was initiated 12 to 24 hours later after completion of the culture tests. The degree of clinical change in the patient's condition was recorded after 24 and 48 hours. Response was judged excellent if there was marked improvement in 48 hours and the infection cleared later on therapy with the same antibiotic; good if there was moderate improvement in 48 hours and the infection cleared later on therapy with the same antibiotic; fair if there was only slight improvement and treatment with a different antibiotic was required to clear the infection; and poor if there was no improvement.

Of the 100 cultures 10% showed no growth. Of the 10 one was an aseptic sebaceous cyst; 2 were taken from patients previously on antibiotic therapy; 4 were from patients with a complaint of sore throat with only slight injection, and may have been viral; and 3 were urine cultures for suspected cystitis or pyelitis.

In the 15 cases where both test paper and disk-agar methods were employed the two methods were found to correlate qualitatively. In all cases the test paper could be read earlier than the agar plate and was found to be easier to interpret.



Comparison of *left,* test paper, and *right,* disk-agar methods for determining antibiotic sensitivity of bacteria. SSS—triple sulfonamide, C—chloramphenicol, E—erythromycin, S—streptomycin, A—chlortetracycline, T—oxytetracycline, TT—tetracycline, and P—penicillin.

Of the 76 patients given initial immediate medication only 23 (30%) showed sufficient clinical improvement within two days to warrant continuation of the first antibiotic. Of the 76 patients 53 (70%) required change to therapy with the antibiotics indicated by the test paper. All 10 of the sterile cultures were found in the 24 patients in whom the antibiotic was withheld, and the remaining 14 (18%) showed excellent to good clinical results on therapy with the antibiotics indicated by the test paper.

It is possible that the excellent results obtained by changing to the antibiotic indicated by the test paper cultures may have been due in part to the initial antibiotic used for from 24 to 48 hours. This was probably not the case, however, since the cultures showed little or no inhibition to those initial antibiotics prescribed at the same time that the culture was started.

Comment

Although bacterial growth takes place as well on blood agar as on the test paper, the paper test may be interpreted much earlier than the disk-agar technique because the result depends on bacterial enzymatic activity effecting a chemical color change rather than on the development of visible colonial growth. Zones of inhibition are more apparent on the test paper, especially in the case of streptococci and pneumococci where the extremely small colonies frequently make the reading of the disk-agar test difficult. Since the test paper is stored in dehydrated form there is no spoilage of the medium or deterioration of the antibiotics, and refrigeration is not required.

TABLE 1.—*Comparison of Tube Dilution, Disk-Agar, and Test Paper Methods for Determining Bacterial Sensitivity to Antibiotics*

TABLE 2.—*Results of Clinical Application of Paper Test of Bacterial Sensitivity to Antibiotics in 100 Patients*

Results	Antibiotic Used Empirically	Antibiotic Changed After Culture on Fair-Poor Group	Antibiotic Withheld Until After Culture Report
Excellent	16	40	13
Good	7	11	1
Fair	31	1*	...
Poor	22	1*	...
Total	76	53	14

* Severe folliculitis responding to third antibiotic to which test indicated best sensitivity. These antibiotics were purposely not started second because they required intramuscular injection once or twice daily.

By clinical trials the test paper was found to be easy to use and reliable. As evidenced by the results in the series of patients studied it appears there is an absolute necessity for sensitivity testing in a surprisingly high percentage of infections seen in office practice. It seems clear that a large number of patients treated empirically with antibiotics do not receive the most effective antibiotic and have an unnecessarily prolonged course of illness. In addition, 10 of the patients in these tests were spared the hazards and expense of antibiotic therapy because of their sterile cultures.

Summary

A new paper test for determining microbial susceptibility to antibiotics was found to have the following advantages: The test is accurate as indicated by comparison with tube dilution and agar plate–antibiotic disk studies. It is simplified so that both medium and antibiotics are contained in one test. No refrigeration is required, because both the medium and the antibiotics are stable. The paper test is easier to interpret than the disk-agar test. Since the test is conducted in a sealed plastic sack there is no odor or danger of contamination, and the entire unit can be incinerated after completion of the test. Clinical studies have been done on 100 patients with the new test; these investigations indicate that a marked improvement in antibiotic therapy is obtained when the test is used together with clinical experience and judgment.

Previously it has been impractical to run routine sensitivity tests in office practice, but this new test paper should provide an extremely useful guide to antibiotic therapy for general office practice.

METHYLPREDNISOLONE (MEDROL) IN THE TREATMENT OF SYSTEMIC LUPUS ERYTHEMATOSUS

ANALYSIS OF RESULTS IN FORTY CASES

Edmund L. Dubois, M.D., Los Angeles

Forty patients with active systemic lupus erythematosus were treated with methylprednisolone. Their ages ranged from 11 to 73 years. The pattern of clinical improvement was similar to that previously seen after the use of prednisone, triamcinolone, and other anti-inflammatory hormones; the fever abated in 24 hours, joint pains disappeared in several days, and pleural effusion and cutaneous lesions subsided in one to several weeks. The doses needed were of the same order of magnitude as those of prednisone and triamcinolone; the mean initial dose was 29.2 and the mean maintenance dose 25.9 mg. per day. While methylprednisolone seemed to differ from the other steroids with respect to some side-effects, the incidence of moonface, hirsutism, acne, and striae was about the same.

Over the past nine years, 325 patients with various forms of systemic lupus erythematosus have been treated with reassurance and rest and, when necessary, salicylates, antimalarials, and steroids.[1] For the last 16 months of this period, 40 patients who required steroid therapy were given a new synthetic, unsaturated, anti-inflammatory hormone: methylprednisolone (Medrol). The purpose of this report is to review experiences with this new agent and compare its results with those of triamcinolone, prednisone, and prednisolone.

Diagnosis and Treatment

Systemic lupus erythematosus is a chronic, multisystemic disorder with many diverse manifestations.[1d] Any system may initially be affected and heal, and patients are subject to many remissions and exacerbations. A thorough history must, therefore, be obtained, and when a patient has, for example, atypical rheumatoid arthritis [2] with pleural effusion, unusual skin lesions, and renal involvement, systemic lupus erythematosus must be considered.

In 80% of typical clinical cases, the diagnosis can be confirmed after repeated testing by finding L. E. cells, which are probably pathognomonic of the disease. A few L. E. cells have been found by myself and others in about 5% or more of patients apparently having rheumatoid arthritis.[3] Prolonged observation will be necessary to determine whether these cases will not terminate, as have similar ones, in overt systemic lupus erythematosus confirmed at autopsy. If cutaneous lesions are present, skin biopsy may confirm the diagnosis in another 10%, and diagnosis in the final 10% often rests on clinical data alone.

Treatment depends on the clinical severity of the illness. Antimalarial therapy is given if salicylates and rest fail or if cutaneous lesions are present; when these measures are inadequate or if the patient is critically ill or has neurological or renal involvement, steroid treatment should be started.

From the Department of Internal Medicine, University of Southern California School of Medicine, and the Los Angeles County General Hospital.

Often, larger than expected amounts of the newer synthetic unsaturated steroids (prednisone, prednisolone, triamcinolone, and methylprednisolone) must be used to control exacerbations of the disease, since these hormones are not as predictable in their effects as are the older corticosteroids, such as cortisone and hydrocortisone. In the milder cases, the estimated amount of steroids is merely added to the therapeutic regimen of the patient. Often this means supplementing the medication of a patient with moderately well-controlled disease who is taking salicylates and antimalarials with small doses of these hormones. Periods of several days to a week or more are permitted to lapse between dosage changes in the milder cases. The increments used here are small, perhaps a 10 to 20% rise at weekly intervals until symptomatic and laboratory improvement is noted.

Table 1.—*Clinical Data on Forty Patients with Systemic Lupus Erythematosus Treated with Methylprednisolone*

	Range	Median	Mean
Age, yr.	11-73	40.0	37.5
Duration of disease, mo.	1-286	72.0	90.2
Duration of all steroid treatment, including methylprednisolone, mo.	1-92	17.5	25.9
Duration of methylprednisolone therapy, mo.*	1-15	4.0	5.0
Dosage, mg. per day			
Initial (21 cases)	8-96	16.0	20.2
Maintenance (40 cases)	6-144	16.0	25.9
Methylprednisolone ratio†			
Prednisone (8 cases)	0.75-1.25	1.1	1.1
Triamcinolone (4 cases)	0.5-1.0	0.9	0.8
Hydrocortisone (3 cases)	2.5-4.2	4.0	3.6
Prednisolone (2 cases)	0.83	0.8	0.8
Cortisone (1 case)	4.2	4.0	...

* Total patient months, 211.

† Methylprednisolone ratio = amount of drug required to produce equal anti-inflammatory effects on milligram for milligram basis, determined by dividing amount of methylprednisolone required for maintenance into amount of older steroids. To ascertain dosage of methylprednisolone to use in transfer, divide therapeutic ratio into 1: for example, with prednisone the therapeutic ratio is 1.1 and the factor is 1 ÷ 1.1 = 0.91 (91%) of the dose of prednisone.

In the severely ill patient, salicylates and antimalarials are not given early in therapy but the patient is immediately placed on therapy with large doses of steroids, such as 400 mg. per day of cortisone. This is done at the beginning in order to reverse rapidly the pathological process before irreversible damage is done. If no response occurs, the dosage of steroid is increased by 25 to 100%, depending on the situation, until improvement is noted. It is advisable to continue giving high dosages of steroids until all abnormal physical findings subside. Advanced renal disease, however, will not be benefited by continued large amounts of these hormones. If there is no change in the renal lesions after two months of adequate therapy, other treatments, such as that with nitrogen mustard, must be considered.[1a]

The clinical picture and hemoglobin level are used as the major guides to steroid therapy. When these normalize, the dosage is reduced slowly, with waiting periods for signs of relapse. More detailed information concerning treatment has been recently published.[1a]

Clinical Material

Forty patients with active systemic lupus erythematosus have been treated with methylprednisolone. The diagnosis was confirmed by findings of L. E. cells in 32 (80%) of the group, positive results of skin biopsy in 6 (15%), and a classic clinical picture in 2 (5%). None of the patients merely had rheumatoid arthritis with a few L. E. cells and no multisystemic disease. There were 30 females (75%) and 10 males (25%). Clinical data on these patients are given in table 1.

Thirty-one patients were receiving salicylate therapy to the point of mild salicylism with their steroids, and 15 were concurrently receiving antimalarial therapy. Ulcer diets and anticholinergics were given to only four patients who had a previous ulcer history and to one patient with an elevated 24-hour uropepsin level before steroid treatment. Sodium restriction was used in only four patients with edema due to nephropathy. Supplementary potassium was given to only one person who was vomiting excessively.

Dosage of Methylprednisolone.—In 21 patients, steroid therapy was initiated with methylprednisolone in a dosage ranging from the addition of 8 mg. per day to the therapeutic regimen of four patients who were on salicylate and antimalarial therapy to 96 mg. per day in a critically ill patient with acute pericarditis, bilateral pleural effusions, and anemia. In the other 19 cases, the patients' conditions had been stabilized on therapy with other steroids and they were then transferred to methylprednisolone therapy (table 1). Two patients were transferred from methylprednisolone therapy to that with other steroids; one, because of a lack of effect of 120 mg. per day, was changed to prednisolone therapy, 120 mg. per day. Subsequently the dosage of the latter steroid was increased to 200 mg. per day without any clinical improvement. The patient died two months later of pulmonary nocardiosis. The other patient was transferred from methylprednisolone to hydrocortisone therapy because of equivocal muscle weakness. This patient subsequently was given methylprednisolone therapy again and has had no further difficulty with it during the nine months prior to the time of writing. The steroid was given in three or four divided doses daily with meals.

Eight patients whose conditions had been stabilized on prednisone therapy were changed to that with methylprednisolone. The new steroid was 1.1 times more potent than prednisone, a methylprednisolone ratio of 1.1. This was determined by dividing the dose of prednisone needed for maintenance by the dose of methylprednisolone required for identical clinical effects. Table 1 lists the ratios of methylprednisolone compared to the older steroids for equal maintenance. The range of methylprednisolone varied between 0.75 to 1.25 times as potent as prednisone. In order to ascertain the amount of methylprednisolone required to change a patient from prednisone therapy to treatment with the new steroid, it is necessary to divide the methylprednisolone ratio into 1, i. e., $1 \div 1.1 = 0.91$; in other words, 91% of the dose of prednisone will be required.

Four patients were transferred from triamcinolone therapy to that with the new steroid. The median methylprednisolone ratio was 0.9 and the mean 0.8. Methylprednisolone was approximately 10 to 20% less potent on a milligram for milligram basis than triamcinoline. Three patients were transferred from hydrocortisone therapy to that with the new steroid, with a median potency of 4 and a mean of 3.6. Two patients were changed from prednisolone to methylprednisolone therapy, and the ratio had a median and mean of 0.8. One patient was transferred from cortisone therapy, and the ratio was 4.2. In three instances, due to exacerbations of the underlying disease at the time of transfer to the newer steroid, no equivalent dosages could be determined.

The maximum maintenance dose was 192 mg. per day in a critically ill patient for two weeks. While she was receiving this dosage, it was noted that she had a miliary pulmonary infiltrate which subsequently proved to be tuberculous. This occurred after two and one-half months of methylprednisolone therapy. The initial chest x-ray was perfectly normal. Two months after institution of antituberculous therapy and gradual reduction of methylprednisolone dosage to a maintenance dose of 16 mg. per day, the lupus erythematosus and miliary tuberculosis markedly improved.

Adjuvant Therapy.—All patients were on a diet with normal salt intake except four who had edema due to nephropathy. They were placed on a 200-mg. sodium diet. There was evidence of sodium retention in two patients who had no nephropathy. Supplementary potassium was given to only one patient who was vomiting. Low serum potassium levels were not noted in any of the patients, even in eight who received maintenance doses of 80 mg. per day or more for as long as two and one-half months.

A routine prophylactic ulcer regimen, usually recommended for patients taking over 50 mg. per day of cortisone or its equivalent, was not used except when indicated and in one patient, noted above, who had an elevated uropepsin level. Unfortunately, peptic ulceration was not prevented in this patient. In four patients peptic ulcers had been diagnosed previously and their ulcer regimen was continued.

Gastrointestinal Studies.—Fifteen patients had upper gastrointestinal x-rays before and every few months during methylprednisolone therapy. One new ulcer, which was asymptomatic, appeared in a patient who received doses ranging from 48 to 192 mg. per day for two months prior to the appearance of a gastric ulcer at the lesser curvature. After two months of ulcer therapy and reduction of the the dose of methylprednisolone to 16 mg. per day, the ulcer was unchanged in size. An 11-year-old girl developed a shallow duodenal ulcer with melena while receiving 96 mg. of triamcinolone per day. This had healed on treatment with an ulcer regimen. Because of a lack of clinical improvement despite a marked moon-face and buffalo-hump appearance, she was transferred one month later to methylprednisolone therapy, 96 mg. per day. Anticholinergic therapy was discontinued at the time of transfer because of obstipation. Ten days later melena recurred. Repeat gastrointestinal x-rays were equivocal. The bleeding ceased with reinstitution of anticholinergic medication and reduction of the dosage of methylprednisolone. Two weeks later the patient died; at autopsy, evidence of disseminated cryptococcosis was found, as well as the changes of systemic lupus erythematosus. No evidence of gastrointestinal ulceration was noted, nor could any other bleeding point be found. In two cases the preexisting ulcers healed with continuation of methylprednisolone and ulcer therapy. These were the only patients in the series who had epigastric distress with this new steroid. In 12 cases there was no evidence of ulceration either before or during treatment. A fourth patient with a history of a healed duodenal ulcer due to steroid treatment was not given x-ray examination during methylprednisolone therapy.

Gastric analyses were performed in seven patients before and every few months during treatment with methylprednisolone. Free and total acidity values were determined before and after subcutaneous injection of 0.1 mg. per 10 kg. of body weight of histamine phosphate. Specimens were drawn every 10 minutes after injection for a total of 40 minutes. No significant changes were noted in any of the patients. Unfortunately, none of the patients who developed peptic ulcers was cooperative enough to have gastric analyses performed serially.

Twenty-four-hour uropepsin level determinations were performed by the method of West and coworkers[4] (in which the normal range is 15 to 40 units per hour) in eight patients before and during steroid treatment. One of the patients who subsequently developed an ulcer had a level of 50 units per hour prior to therapy but a normal level while receiving methylprednisolone plus an ulcer regimen. Despite this, a gastric ulcer appeared after two months of high dosage therapy, as noted above. Levels in the other seven patients remained within normal limits. Serial uropepsin studies were not available in the two other patients who had peptic ulcers.

A control group of nine patients with systemic lupus erythematous has been treated with prednisone without an ulcer regimen for periods up to 18 months. They have had serial upper gastrointestinal x-rays. One peptic ulcer has appeared.

Results of Therapy

The pattern of clinical improvement closely paralleled that obtained in systemic lupus erythematosus by previous treatment with corticotropin and other anti-inflammatory hormones. The fever abated in 24 hours, provided that the dose of corticosteroid was adequate, joint pains disappeared in several days, and pleural effusion and cutaneous lesions subsided in one to several weeks. Three patients had mild nephropathy of short duration characterized by normotension, albuminuria of about 2+, minimal edema, granular hyaline casts and red blood cells, hypoalbuminemia without hypercholesteremia, and no nitrogen retention. This completely cleared in all patients receiving methylprednisolone therapy. Seven patients had more advanced renal disease: a nephrotic picture of anasarca, elevated cholesterol levels, nitrogen retention, and urinary sediments containing fatty casts and oval fat bodies. None of these was benefited by methylprednisolone treatment. In no case was the edema aggravated by treatment with this corticosteroid, even in doses of 144 mg. per day for periods up to three weeks. Four received nitrogen mustard with amelioration of the disease process. Six of this group of seven patients were benefited by treatment with chlorothiazide (Diuril).

Table 2.—*Clinical and Laboratory Changes in Forty Patients with Systemic Lupus Erythematosus Treated with Methylprednisolone*

	Values			Cases		Triamcinolone Group

Increased in number				0	0	0

There was a decrease in weight in 11 patients (27.5%), compared to 18 (62%) of a comparable group of 29 patients treated with triamcinolone (table 2). The median loss was 12 lb. (5.4 kg.). Six patients gained weight, with a median increase of 8 lb. (3.6 kg.). Weight remained unchanged in 22 (55%) of the group, compared to 8 (28%) of the triamcinolone group. The weight changes which occurred with methylprednisolone therapy were gradual and occurred over weeks or months. Appetite stimulation was less marked with methylprednisolone than with prednisone and the older steroids. The anorexia often noted with triamcinolone therapy was not seen.

The mean blood pressure was unchanged in 27 patients (67%), compared to 20 (69%) of the triamcinolone series. It decreased in 8 patients an average of 14 mm. Hg and increased in only five patients an average of 15 mm. Hg.

Laboratory Findings.—The hemoglobin level remained unchanged in half the cases. These patients had normal levels to start with, since in most of them adequate control had been achieved with other steroids prior to transfer. The hemoglobin level increased a median of 2.3 Gm. % in 15 cases (table 2).

White blood cell counts were unchanged in 35% and in half the cases increased an average of 3,800 cells per cubic millimeter. The Wintrobe sedimentation rate (uncorrected at 60 minutes) was unchanged in 27.5% and decreased in 35% of the group; it increased in only 10%.

L. E. cell tests, performed by the rotary method, showed no change in quantity in 9 cases, full disappearance in 4, and continued absence in 24.[5] The data are comparable to those in the triamcinolone series, since in that group the majority of patients had no L. E. cells present at the time of transfer to that steroid.

Side-effects.—The side-effects are reviewed in table 3, with comparison of methylprednisolone to triamcinolone and prednisone and prednisolone in similar patient groups treated by myself. Moonfaced appearance occurred in 52% of the methylprednisolone group as against 45% of the triamcinolone series and 49% of those receiving prednisone or prednisolone. This is certainly not a significant difference. Three weeks to several months or more were required for development of this change.

Hirsutism was definitely less marked than with triamcinolone, and in the few patients in whom it occurred it was mild. Acne occurred less often—in only 10% compared to 17% with triamcinolone and 16% with prednisone or prednisolone. Marked striae formation was noted in only one patient (3%) on methylprednisolone therapy, compared to 14% of the triamcinolone series and 3% of those receiving prednisone or prednisolone.

The one side-effect which was more pronounced with methylprednisolone than with the other steroids in systemic lupus erythematosus was a tendency toward the development of ecchymoses, noted in 27% of this group as against 14% of the triamcinolone group and only 3% of those on prednisone or prednisolone therapy. Accumulation of edema was noted in only two patients, one of whom had anemia uncorrected by methylprednisolone. Diabetes mellitus did not appear in any case. Fasting blood sugar levels were repeatedly obtained in these patients, and they remained within normal limits. None of the patients had diabetes prior to treatment.

Epigastric distress after intake of the medicament was not noted. A new peptic ulcer appeared in one patient, whose case was described above. This incidence compares favorably to that with triamcinolone when used without a prophylactic ulcer regimen and to those with prednisone and prednisolone when used with an ulcer regimen (see addendum).

Muscle weakness of the type described as occurring with triamcinolone therapy was not noted in any patient.[2] One patient who initially had some transitory weakness on methylprednisolone therapy had no recurrence of it on reinstitution of therapy with this corticosteroid. The follow-up period on this patient has been nine months. This patient and one additional one in this series had had muscle weakness on triamcinolone therapy.

Comment

Methylprednisolone is an effective new unsaturated corticosteroid with minimal ulcerogenic potency. Its common side-effects are similar to those produced by the older steroids, except for the higher incidence of ecchymoses—27% as against 14% with triamcinolone and 3% with prednisone and prednisolone. Muscle weakness was not noted in any case.

Of 18 patients who had received prior steroid therapy, 2 were benefited more by methylprednisolone than by the older steroids. One was an 18-year-old girl who had progressive extensive striae formation and marked moon face, buffalo hump, and central obesity after four months of triamcinolone therapy despite reduction of dosage during the last six weeks to 6 mg. per day. Six weeks after transfer to therapy with methylprednisolone, 16 mg. per day, the striae began to fade and the patient had less activity of her illness and her appearance became more normal. A 43-year-old woman had better over-all control of her illness with methylprednisolone than with triamcinolone, prednisone, or hydrocortisone.

The advantages of this new steroid from this standpoint were not as marked as in the triamcinolone series, where 7 of 14 patients who had been treated with other steroids were given better control with triamcinolone than with other agents. This individual variability in response to the corticosteroids suggests that, if the illness is inadequately controlled by increasing doses of one steroid, occasionally transfer to another may help. As far as transferring to another hormone to eliminate undesirable side-effects is concerned, the only ones I have seen disappear (provided the effective hormonal dose is similar) are the muscle weakness and excessive striae formation induced by triamcinolone. The usual moon-face appearance is not benefited by hormone transfer. The only effective means of combating this side-effect is reduction of the dose of steroid with synergistic therapy including salicylates and antimalarials.

The incidence of new peptic ulceration in my series of patients on methylprednisolone therapy (3% of 40 cases) is the same as that noted with triamcinolone (4% of 29) and prednisone and prednisolone when used routinely in conjunction with an ulcer diet (3% of 37) (see addendum). In the methylprednisolone and triamcinolone series no routine prophylactic ulcer regimens were utilized. The occurrence of peptic ulcer in patients with rheumatoid arthritis treated with prednisone or prednisolone without a prophylactic ulcer regimen has been reported to be as high as 31%.[6]

TABLE 3.—*Side-effects of Methylprednisolone Compared to Those of Triamcinolone and Prednisone and Prednisolone*

	Methylprednisolone (40 Cases)		Triamcinolone (29 Cases), %	Prednisone and Prednisolone (37 Cases), %
	No.	%		
Moon face, buffalo hump				
After transfer from older steroids				
Increased	2	5	14.0	12.0
Decreased	1	3	0	5.0
Unchanged	9	22	14.0	17.0
Initial appearance, methylprednisolone as first steroid	6	15	14.0	15.0
Initial appearance, transfer to methylprednisolone from other steroids	3	8	3.0	0
None at any time	19	48	55.0	51.0
Total	21	52.0	45.0	49.0
Marked hirsutism	3	8	21.0	3.0
Acne	4	10	17.0	16.0
Striae (marked)	1	3	14.0	3.0
Ecchymoses (marked)	11	27	14.0	3.0
Edema	2	5	3.0	6.0
Diabetes mellitus	0	0	3.0	6.0
Epigastric distress	0	0	6.0	3.0
Peptic ulcer*	1	3	4.0	3.0
Muscle weakness	0	0	19.0	0.0

* Patients on triamcinolone therapy were not on prophylactic ulcer regimen, whereas all those on prednisone or prednisolone therapy were whenever maintenance dose was over 10 mg. per day of either drug (see addendum).

The mechanism of ulcer formation in steroid-treated patients remains unsolved. In my experience and in that of others there is no elevation of gastric hydrochloric acid or uropepsin levels. Janowitz and co-workers[7] have shown delayed healing of experimentally produced gastric ulcers. The theory of a reduction of viscosity of gastric mucus by steroids has not been confirmed.[6] The fundamental defect producing ulceration is probably inhibition of wound healing caused by a very high local steroid level in the stomach interfering with closure of normal, spontaneously induced gastric ulceration and in addition to the systemic effects of the steroids acting in a similar manner. The incidence of peptic ulcer is highest in the arthritic groups because of the associated ingestion of large amounts of salicylates and, in some cases, phenylbutazone (Butazolidin).

Summary

Forty patients with systemic lupus erythematosus have been treated with a new synthetic, unsaturated corticosteroid, methylprednisolone (Medrol), for as long as 15 months. This hormone is 1.1 times as powerful as prednisone and four times more potent than hydrocortisone as an anti-inflammatory agent. It is only 0.9 as strong as triamcinolone in this regard. The initial dosage varied from 8 mg. per day added to the therapeutic regimen of a patient with mild disease partially controlled by rest, salicylates, and antimalarials to 96 mg. per day in a critically ill patient. The average dose was 30 mg. per day, with maintenance dose of 26 mg. There was no evidence of sodium retention or potassium loss. Routine sodium restriction, potassium supplementation, and prophylactic ulcer regimens were not used.

Fifteen patients had upper gastrointestinal series prior to and every two to three months during therapy. There was evidence of new peptic ulceration in only one, treated with 48 to 192 mg. per day for two months before the appearance of an asymptomatic gastric ulcer. She had been on a prophylactic ulcer regimen because of a high control uropepsin level. In two of these serial studies, preexisting peptic ulcers were noted; these patients were the only ones who had gastrointestinal distress while taking methylprednisolone. In the 12 other cases there was no evidence of ulceration. Seven patients had serial gastric analyses performed before and during methylprednisolone therapy. No changes were noted. Eight patients had 24-hour uropepsin studies done at similar intervals. One had an elevated level prior to treatment, and she developed gastric ulcer despite a prophylactic ulcer regimen. Her uropepsin level decreased shortly after treatment was begun and before the ulcer was noted.

The pattern of clinical improvement closely paralleled that obtained by previous treatment with older steroids. There was a disappearance of all the clinical and laboratory abnormalities produced by the disease, with the exception of long-standing renal involvement.

The incidence of side-effects, such as moon face, hirsutism, acne, and striae, was about the same as was found in a similar series of patients treated with triamcinolone and with prednisone and prednisolone. However, ecchymoses occurred in 27% and were more prominent with methylprednisolone than with the older anti-inflammatory hormones, including triamcinolone. Diabetes mellitus did not appear in any patient. Muscle weakness was not noted with use of this steroid. Moon face, buffalo hump, and central obesity produced by therapy with other steroids did not disappear after transfer to an equivalent dose of methylprednisolone in any case.

Of 18 patients who had received prior steroid therapy with other anti-inflammatory hormones, only two had better control and felt better on methylprednisolone therapy than they had on that with the other corticosteroids. Methylprednisolone is a relatively safe and potent anti-inflammatory agent for initial and maintenance steroid therapy in patients with systemic lupus erythematosus.

Addendum

An additional patient with systemic lupus erythematosus for whom data are not included in this paper received 32 mg. of methylprednisolone per day for seven months without a prophylactic ulcer regimen. Her base-line upper gastrointestinal series was normal. An asymptomatic gastric antral ulcer was noted on the repeat examination at the end of this therapy. This brings the total ulcer incidence with this steroid to 2 cases out of 40, or 5%.

A review by Dr. James G. Bulgrin of the radiology department of all the gastrointestinal x-rays done on 70 patients with systemic lupus erythematosus has revealed the presence of two additional ulcers in the triamcinolone series, making a total of 3 cases out of 29, or 10%. One patient in the control group of nine persons receiving prednisone alone without an ulcer regimen has developed an ulcer, making the incidence 11% in that series.

CLINICAL NOTES

FAULTY FUNCTION OF TABLE MODEL ETHYLENE OXIDE STERILIZER

Carl W. Walter, M.D.
and
Ruth B. Kundsin, Sc.D., Boston

Ethylene oxide has been used in industry for two decades for the sterilization of materials which cannot withstand steam sterilization. Hospital applications have awaited development of equipment suitable for the gamut from small instrument sterilization in a physician's office to the sterilization of hospital equipment and bedding. A large walk-in type of ethylene oxide sterilizer has been developed [1] and is currently being used at the Peter Bent Brigham Hospital for sterilization of furniture, bedding, rugs, draperies, and equipment which cannot be steam sterilized. The process involves five steps: heating the load to 140 F; evacuation of air from the load; humidification to achieve a moisture content of 25 to 30%; introduction of ethylene oxide, inerted by the addition of carbon dioxide, to a level of 760 mg. per liter; and exposure of three hours. The whole process is automatic, and tests with spores of Bacillus subtilis and Clostridium sporogenes have shown that under the conditions of the automatic cycle sterility invariably results.

Results of Test of Sterilizer

A table model ethylene oxide sterilizer has recently been marketed under the name Ben Venue sterilizer, designed for sterilization of instruments and materials that are destroyed by exposure to steam. This sterilizer is a compact, chromium-plated cylinder with a capacity of approximately 1 liter. The capacity can be increased by the use of a 5-in. extension sleeve. The ethylene oxide used with the sterilizer is provided in steel cylinders called Steribulbs, containing a total of 12 Gm. of ingredients of which the manufacturer states that 20% is ethylene oxide and 80% is inert. A plunger device attached to the side of the cylinder impinges the Steribulb on a penetrating needle that releases the gas into the sterilizing chamber. The directions with the instrument recommend a two-hour exposure, after which the contents are assumed to be sterile. The whole process is carried out at room temperature and at the prevailing relative humidity.

Experience in testing this sterilizer has indicated that sterility does not invariably result when the accompanying directions are followed. The test organism, B. subtilis (a strain secured from Dr. L. F. Ortenzio), was grown in soil extract broth. Loops made from size 3 silk suture were dipped into a 72-hour culture and dried for at least 24 hours at room temperature according to the method suggested by Ortenzio and co-workers.[2] The contaminated suture loops were placed into paper envelopes and exposed to ethylene oxide in the Ben Venue sterilizer. After exposure, the loops were dropped into nutrient broth and incubated at 36 C for two weeks. The results are shown in table 1.

Another series of tests was conducted with use of sterility control pledgets impregnated with spores of Cl. sporogenes, prepared by the Baltimore Biological Laboratory. After exposure to the ethylene oxide these pledgets were dropped into thioglycollate broth for sterility observation over a period of seven days. The results are shown in table 2.

The criticism can justifiably be made that this sterilizer was primarily designed for instrument sterilization and, since the tests noted in tables 1 and 2 involve the use of spores on silk or cotton fibers, the results are not good approximations of spores on metal instruments. To test the sterilization of contaminated steel surfaces, six stainless steel slides, measuring approximately 1 by 3 in., were contaminated with 1×10^6 B. subtilis spores. The slides were allowed to dry for 48 to 72 hours and were then exposed to ethylene oxide in the Ben Venue sterilizer. The results are shown in table 3.

Comment

The results of our tests indicate that the use of the Ben Venue sterilizer, according to the directions given by the manufacturer, is not a satisfac-

---

tory method of sterilizing either spore-contaminated fiber or steel. We have not used vegetative bacterial cells in our testing, and it may very well be that this method is adequate for their destruction. However, since the word "sterilization" implies the death of all living organisms, this piece of equipment cannot legitimately be called a sterilizer.

We appreciate the fact that the dry spores used in the tests described here are extremely resistant to sterilization and have been a severe test of the sterilizing efficiency of the equipment. However, in practical application, one has no guarantee of the degree of resistance of organisms on material to be sterilized. Instruments which have become contaminated and have been allowed to dry for a day or more before sterilization can certainly be assumed to contain dessicated spores.

Ethylene oxide, in both liquid and gaseous form, has been found to be an efficient sterilizing agent. However, many factors influence the death rate of organisms exposed to it—such factors as relative humidity, temperature, concentration, and degree of contamination of material to be sterilized.

It is entirely conceivable that a workable table model ethylene oxide sterilizer can be devised which will be satisfactory once these factors are taken into consideration. A heating unit incorporated in the apparatus would rapidly accelerate the rate of kill. Phillips[3] has calculated a Q_{10} of 2.74 for ethylene oxide; thus, a 10-C rise in temperature would more than double the rate of kill. Some arrangement for securing an optimum relative humidity of 28%[4] in the sterilizer would also be advisable.

EXPOSURE TO BERYLLIUM.—The physician is hindered in diagnosing chronic beryllium disease by the fact that the worker-patient frequently does not know the nature of the materials with which he or those around him have worked. Furthermore, this work exposure may have terminated more than a decade prior to the onset of current clinical symptoms. . . . Although there have been no reports of beryllium disease in miners of the ore, beryl, which contains from 2% to 12% beryllium, the subsequent extraction process has been frequently implicated in the disease. The manufacture of fluorescent tubes constituted a second major source of toxic exposure in that phosphors used from 1938 to 1949 often contained from 2% to 14% beryllium, generally as zinc-manganese-beryllium silicate. This hazardous use of beryllium was discontinued in 1949 by mutual agreement of the manufacturers. No such self-regulation has applied to the "neon" sign producers, many of whom operate small backyard or garage "factories" and who may freely obtain and process beryllium oxide in the preparation of phosphors. . . . Beryllium is used in windows of x-ray tubes because it is easily penetrated by the rays and is stable at high temperatures. It is also employed in nuclear energy projects, since it readily yields neutrons under alpha particle bombardment. . . . Because of its lightness, rigidity, and resistance to heat, beryllium is today finding use in structural parts of high-velocity space vehicles. The oxide may be used in heat-resistant ceramic nose-cones. . . . Typists, clerks, engineers, and janitors, though they do not directly use beryllium, may be affected because of atmospheric contamination. Furthermore, neighborhood atmospheric contamination or beryllium-containing dusts brought home on work clothes may lead to disease in persons remote from any plant.—H. L. Hardy, M.D., and L. B. Tepper, M.D., Beryllium Disease: A Review of Current Knowledge, *Journal of Occupational Medicine,* April, 1959.

ORTHOSTATIC APHASIA AFTER CARDIAC SURGERY

Houck Bolton, M.D., Philadelphia, David L. Andrus, M.D.
and
Emund C. Hessert, M.D., Camden, N. J.

Orthostatic aphasia is a term applied to that condition in which the patient becomes aphasic when in the sitting or upright position. The cause of this phenomenon is unknown. However, it must be assumed that there exists a relative ischemia affecting the essential centers and/or the associated fiber tracts which control the motor function of speech. When a patient is in the supine position there is adequate blood supply to these areas, permitting them to function normally. Resumption of the upright position slightly diminishes this blood supply, resulting in the production of cerebral ischemia and aphasia.

After cardiac surgery numerous complications may occur. Arterial embolization during the correction of mitral stenosis is not uncommon. Bolton and Bailey[1] have reported various neurological and neuropsychiatric phenomena in the cardiac patient after surgery. However, in a series of well over 2,000 such patients operated on for valvular lesions, Bolton and Musser[2] have not observed orthostatic aphasia. To our knowledge, this case represents a complication which has not been previously reported.

Report of a Case

A 47-year-old married female was admitted to West Jersey Hospital on Jan. 28, 1959, with a history suggestive of rheumatic activity occurring in childhood; her condition had been diagnosed as acquired mitral valvular stenosis after discovery of a heart murmur 27 years prior to this admission. Though never in frank congestive failure, she had demonstrated atrial fibrillation for many years and her condition had been maintained with digitalis for a period of no less than 20 years. Her general cardiac status had progressively declined in spite of constant and diligent medical therapy, and at the time of admission her functional capacity was 2-3 according to the American Heart Association classification.

She remained symptom free until four years prior to admission, when she experienced an episode of cerebral embolization which was manifested by hemiplegia on the left. For a period of approximately three weeks the patient was aware of sensory aberrations, predominantly numbness, involving the entire left side. At this time her course proceeded uneventfully, with no evidence of residua. During the ensuing four years she had noted slowly progressing exertional dyspnea.

On Jan. 28, 1959, the patient experienced excruciating pain localized to the left popliteal space, with associated absence of the popliteal pulse and discoloration of the extremity distal to the knee. Oscillometric readings and marked local temperature decrease substantiated the diagnosis of arterial occlusion involving the popliteal vessel. A regimen of anticoagulants and supportive therapy, including lumbar block, proved effectual, and 23 days later the patient successfully withstood a mitral commissurotomy. The operation was accomplished without event, and a most satisfactory technical result was obtained.

Approximately 72 hours postoperatively, with the patient in the semi-Fowler position to facilitate expectoration, she attempted to speak and found she was unable to articulate. The bed was promptly lowered so that she was in the supine position, and within several seconds her enunciation was normal. Vital signs were immediately obtained and revealed no change from previous recordings. The patient was alert and cognizant of her condition. She demonstrated no particular concern or emotional disturbance with this experience and expressed her reaction by stating that she "felt silly" because she could not talk. Within a period of several hours it was noted that the left angle of the mouth was slightly depressed. After the initial episode she was placed in a sitting position only in the presence of a physician. A stellate ganglion block effectively produced the expected Horner's syndrome and contributed to her general supportive therapy. It is interesting to note that on each occasion her orthostatic aphasia essentially mimicked the original pattern, with no change in vital signs, clinical picture, or laboratory studies. This condition existed for a period of four days and then spontaneously subsided.

Her remaining postoperative course was punctuated by a profuse menses aggravated by anticoagulant therapy. The patient was discharged on the 11th postoperative day in good condition.

Comment

It is our belief that this patient suffered a minimal postoperative cerebral embolus which produced a relative ischemia affecting her speech

center (Broca's area) or associated fiber tracts and that while the blood supply was sufficient to maintain this area with the patient in the supine position, thus allowing her to articulate, it was inadequate to do so in the upright position.

NATURE OF ADVERSE REACTIONS TO RADIOPAQUE AGENTS

PRELIMINARY REPORT

Sidney S. Sobin, M.D., Ph.D., Wallace G. Frasher, M.D., George Jacobson, M.D.
and
Frank A. VanEeckhoven, Los Angeles

The nature of the adverse reactions to the intravascular administration of radiopaque agents is not known.[1] Such reactions or complications vary from mild, with nausea and vomiting and urticaria, to severe, with syncope, shock, convulsions, respiratory distress, and focal hemorrhage, to fatal. They occur with intravenous urography, angiocardiography, regional aortography, and arteriography. It is difficult to arrive at an over-all estimation of reaction rates, due to different criteria of what constitutes a "reaction" as well as variables in observing and reporting. From our observations, as well as those in the literature, it would appear that reactions increase with increasing dose, concentration, and speed of injection of these substances. Although the reaction rate, in the main, has decreased with the introduction of newer agents, their increased use in a wide variety of diagnostic situations has resulted in an increased incidence of reactions.

For reasons to be detailed elsewhere,[2] we have studied the effect of the compounds diatrizoate (Hypaque) sodium and sodium diprotrizoate (Miokon sodium) on the small blood vessels at the corneal-scleral junction in man and rabbits. A modification [3] of the standard binocular dissection microscope method has provided greater facility in use of this equipment and increased light for photomicrography. The magnifications used allowed arterioles and venules of 75 μ or larger to be easily observed.

The corneal-scleral blood vessels were studied in 24 adult male patients who received roentgenographic contrast mediums for intravenous urography. None of these patients was acutely ill at the time of study. Diatrizoate sodium (30 cc. of 50% solution) or sodium diprotrizoate (20 cc. of 50% solution) was given intravenously in 45 to 60 seconds. In a few patients nausea without vomiting occurred.

In 20 of 24 persons so studied, characteristic changes occurred in the corneal-scleral vessels after the administration of these materials. These changes varied only in degree from patient to patient. The vascular alterations were first seen one to two minutes after the end of the injection. There was marked slowing of the microcirculation, and the fine granular appearance of the erythrocyte column was quickly replaced by a much coarser granularity with red blood cell masses and clear irregular intravascular plasma zones between the red blood cell masses. Variable degrees of vasoconstriction were noted in both minute arterial and venous vessels with marked irregularity in blood vessel margins resulting in a scalloped edge. At times there was almost complete pinching off of the red blood cell column and formation of sausage-like masses which moved slowly down the vascular trunk. Despite the numerous red blood cell aggregates, actual stasis did not occur. Pinched off masses moved slowly and erratically to the confluence with larger vessels and then disappeared into the more rapidly moving larger stream. There was an over-all decreased vascularity in the microscopic field. The intensity of these vascular alterations was maximal at four to six minutes after the injection, and although no attempt was made to follow the return of the vascular bed to normal in all persons, in most instances

it had returned to its previous state 20 minutes after the administration of the radiopaque material.

Similar observations were made at the corneal-scleral vessels of immature (250-Gm.) albino rabbits lightly anesthetized with urethan. The radiopaque substances, diatrizoate sodium, sodium diprotrizoate, and sodium acetrizoate (Urokon sodium), were given through a fine catheter inserted into the jugular vein in amounts proportionate to that used in angiocardiography in man. The changes in the corneal-scleral vessels were identical to those seen in man, although the time of onset of these alterations was markedly shortened and the total reaction more intense.

These observations may provide some rational basis for the understanding of the reactions to the radiopaque agents. The precise cause and nature of the blood vessel changes and the red blood cell aggregates is not known, and only with such knowledge can the exact cause of these reactions be determined and ultimately prevented.

COUNCIL ON DRUGS

Report to the Council

The Council has authorized publication of the following sixth and final paper, which was presented as part of a symposium-panel discussion held in Washington, D. C., Sept. 25, 1958, on The Use and Abuse of Adrenal Steroids. The first five papers appeared in THE JOURNAL *on June 20 and 27 and July 4, 11, and 18, 1959, pp. 952, 1063, 1179, 1311, and 1411. The panel discussion which concluded the program is available in mimeographed form in the Secretary's Office, Council on Drugs.*

STEROID THERAPY IN OPHTHALMIC LESIONS

Irving H. Leopold, M.D., D.Sc., Philadelphia

Since the advent of cortisone approximately a decade ago, numerous steroids and steroid derivatives have been evaluated for their ocular effects when administered locally and systemically. These include cortisone (Cortisone, Cortogen, Cortone) acetate and free alcohol, hydrocortisone (Cortef, Cortril, Hycortole, Hydrocortone) acetate and free alcohol, hydrocortisone tertiary-butylacetate, prednisolone (Delta Cortef, Hydeltra, Meticortelone, Meti-Derm, Paracortol) free alcohol and acetate, prednisolone butylacetate (Hydeltra-T. B. A.), methylprednisolone (Medrol), triamcinolone (Aristocort, Kenacort), and dexamethasone (Decadron, Deronil). Not all of these have had completely adequate trial in ophthalmology. However, when topically applied, only minor differences in clinical activity have been noted. If employed in individual dosages and proper vehicles and method of administration, all have equivalent anti-inflammatory potency for ocular diseases. For ophthalmic therapy, these agents may be applied locally in solution or ointment vehicles or injected subconjunctivally. There appears to be no significant advantage to intracameral injection. They may also be used systemically. Corticotropin (ACTH, Acthar, Corticotropin, Cortrophin) is employed intravenously or intramuscularly for ocular diseases.

The present trend is to use corticosteroids in preference to corticotropin because of the ease of administration and the effectiveness of locally applied forms. Local routes are preferred over systemic ones because of the ease of administration, lower cost, and freedom from systemic side-effects, which allows treatment to be continued safely over a long period of time.[1]

It has been established that steroids do not act on the cause of ocular disease but do reduce the reaction of the tissues to an exciting agent. They

---

Professor and Head of Department of Ophthalmology, Graduate School of Medicine of the University of Pennsylvania, and Attending Surgeon and Director of Research, Wills Eye Hospital.

suppress hypersensitivity reactions and inflammations due to infection, inhibit neovascularization, reduce fibroblastic activity, and interfere with some immunological reactions.[2] Minor differences in local activity have been demonstrated clinically and experimentally; e. g., hydrocortisone locally instilled has been shown to be more effective than cortisone for vernal conjunctivitis.[3] The effectiveness of each is approximately the same for other anterior segment inflammations when applied topically.

Penetration studies have revealed a difference, in ability to penetrate, of the acetate and free alcohol varieties of cortisone, hydrocortisone, prednisone (Deltasone, Deltra, Meticorten, Paracort), and prednisolone. It has also been demonstrated that the acetate variety of hydrocortisone penetrates more readily through the cornea than the more soluble phosphate and succinate forms.[4] This may account for the slightly greater anti-inflammatory action of the less soluble derivatives when administered locally.[5] Studies of penetration of systemically applied steroids did not show a clear-cut relationship between the ease of penetration and antiphlogistic action.[6]

Experimental and clinical studies over the past 10 years have revealed that, in anterior ocular inflammations, locally applied steroids are equal in effectiveness to systemically administered steroids or corticotropin.[7] In posterior segment inflammations, local routes appear to be inferior to systemically administered steroids or corticotropin. Steroids given systemically seem to be equivalent to corticotropin for most of the responsive posterior segment conditions.[8]

Since steroids are easily administered systemically, they are usually preferred over corticotropin for equally responsive conditions. However, corticotropin may be preferred for severe inflammations that threaten the functional integrity of the eye. In severe intraocular infections, corticotropin given intravenously, which mobilizes many adrenal steroids, is preferred to oral therapy with steroids for the purpose of reducing inflammatory reactions until the infecting agents can be overcome by the specific antibiotic.[9] As in other areas of the body, hormonal therapy is used in ophthalmology for the sole purpose of controlling inflammation until the ocular defenses can handle the problem; they have no curative effect on ocular diseases and possess no bactericidal or tissue-stimulating activity. In ocular pathology the effect of the hormones is not to make up a deficiency of hormones; they inhibit inflammation, whether it be due to allergic, toxic, infectious, or traumatic etiology. If the stimulus is great, the steroids may not prove adequate to block the reaction.

Topically and systemically administered steroids produce favorable results in such external inflammations as contact dermatitis, rosacea keratoconjunctivitis, vernal conjunctivitis, allergic conjunctivitis, allergic keratoconjunctivitis, marginal corneal ulcers, and phlyctenulosis. There are a number of ocular conditions that are not benefited including pemphigus and, in many cases, nodular episcleritis. Episcleritis, scleritis, and ocular manifestations of collagen disease have shown irregular responses.[10]

Steroids prove most useful in nongranulomatous uveitis of both the anterior and the posterior varieties. Uveitis due to sarcoid may respond incompletely. Recurrences are frequent and are not always quieted by additional or continued administration of steroids.

Sympathetic ophthalmia is best treated initially by intravenous administration of corticotropin and carried to the point of quiescence by steroids given systemically and locally. The continuous gradual reduction of steroids may demand a year or more until therapy is no longer required.

Occasionally, but rarely, one steroid might succeed in controlling an ocular disease in which another in large dosage has failed. Isolated examples of dramatic improvement have been seen, but this is not the usual experience of the majority of ophthalmologists dealing with degenerative diseases. Most of the results with degenerative ocular diseases are not impressive. Optic neuritis and retrobulbar neuritis seem to quiet more rapidly with the institution of steroids, particularly corticotropin given intravenously.

Steroids have been shown to be contraindicated in corneal ulcers due to herpes simplex[11] and fungi.[12] Bacterial ulcers may respond in the presence of steroids if the anti-infectious therapy has been specific, properly administered, and in adequate dosage. The same applies to conjunctivitis of similar etiologies.

In dealing with conjunctivitis, it is fairly well recognized that ideal therapy demands specific diagnosis. It is true that one cannot always be certain of etiology. Cultures and cytological studies are helpful but expensive. Most conjunctival inflammations subside spontaneously. Steroid therapy may reduce the local reaction but may interfere with natural resistance. Therefore, it is recommended that steroids not be used as a substitute for clinical acumen. One should employ less hazardous and usually less expensive medicaments such as astringents, zinc preparations, quaternary ammonium compounds, or even saline irrigations until the cause of the disease is indicated or until cultures and smears can aid in the selection of specific medicaments. After such a course, one is less likely to enhance the development of dendritic keratitis or corneal fungous infections. Both of these types of infections have increased in severity and incidence since the advent of locally administered steroids. It has been noted repeatedly that the patient undergoing local therapy with steroids may have less discomfort and see his physician less frequently; consequently, the gradual progression of the disease may go undetected until late in its course.

Fungous infections of the cornea can readily be produced experimentally by pretreatment with steroids. This has been demonstrated by Ley and Sanders[12b] and by Montana and Sery.[12c] Perhaps a safe rule to follow for the local use of steroids in external ocular disease is this: when a doubt exists as to diagnosis or to the likelihood of a favorable response to steroids, steroids should not be used.

There is also a contraindication to systemic administration of steroids in granulomatous uveitis and intraocular infections that might be of fungal or perhaps viral origins. It has been demonstrated that steroids have a disastrous influence on experimental fungal choroiditis whether this is due to Candida albicans or to *Aspergillus*.[13] The injection of steroids during the course of such an experimental infection causes exacerbation of the inflammation in a disease which is often otherwise self-limited.

Similarly, Woods has demonstrated less favorable response in acid-fast intraocular infections with steroids alone. Uveitis due to sensitivity to tuberculoprotein can react favorably to steroid administration. The difficulty is to determine the etiology. Perhaps simultaneous administration of antituberculosis drugs in adequate concentration might prevent the unfavorable effects of steroids on tuberculous uveitis. However, when one is reasonably certain of a tuberculous etiology in uveitis but cannot determine relative rate of infection and hypersensitivity, the specific antituberculosis chemotherapy should be employed first and steroids added to this later if the results have not been favorable and if the uveitis is still considered to be of tuberculous etiology.

There is some clinical evidence that steroids are not harmful in toxoplasmic uveitis. However, the diagnosis here is not certain, and the favorable results may be due to another cause.

Sympathetic ophthalmia and sarcoids are examples of granulomatous uveitis that can respond favorably to long-term therapy. However, long-term treatment has many hazards. The over-all rule that can be applied to steroids in ophthalmology would be to use steroids when long-term therapy is necessary in those ocular conditions in which no other therapy with fewer side-effects is known to be helpful. The crucial word in this sentence is "helpful," for the steroids must be known to have been helpful in the condition before they are employed on a long-term basis. Steroids should not be used simply because the ophthalmologist knows nothing else to do.

Summary

Corticosteroids and adrenocorticotropic hormones given systemically are of considerable value in the therapy of ocular disorders. There are undesirable ocular effects from corticosteroids such as the development of and/or enhancement of herpes simplex keratitis and fungal keratitis after local corticosteroid ocular instillations, and there are the possibilities of undesirable side-effects from the long-term systemic administration of corticosteroids and corticotropin. These agents should be used only for those ocular conditions in which definite benefit has been demonstrated. They should not be used simply because the physician knows nothing else to do for the ocular disorder. Steroids are of limited value in the management of infectious diseases. They certainly should not be used in the treatment of ocular infectious disease without adequate specific antimicrobic coverage. Long-term therapy with steroids in ocular disorders should be avoided unless there are specific indications.

gree of correlation has been obtained in tests for achlorhydria in which the azure A resin method and the conventional gastric analysis by intubation were used. It should be understood, however, that, when caffeine is used as the stimulant to gastric secretion prior to the administration of the resin, the azure A method determines what might be called a caffeine achlorhydria. True achlorhydria can be determined only if the most powerful stimulants to gastric secretion, such as betazole or histamine, are used.

The azuresin test does not furnish exact quantitative results. However, it is convenient for screening patients with minor gastric symptoms that are not considered sufficiently significant to warrant the discomfort of intubation gastric analysis or other more expensive diagnostic procedures. It should not be used in lieu of more extensive examinations whenever these are indicated. When the test indicates achlorhydria, some clinicians advocate confirmation of these results by repeating the test, using histamine or betazole as the stimulant to gastric secretion. The resin test method for achlorhydria is considered useful for the diagnosis of suspected cancer of the stomach, pernicious anemia, and gastric polyps.

Azuresin is of negligible toxicity, and, to date, no instances of drug idiosyncrasy have been reported (as was sometimes the case with the older quinine resin). The test may be carried out without regard to previous or concomitant drug therapy. However, tubeless gastric analysis may be inaccurate in the presence of pyloric obstruction, severe hepatic or renal disease, abnormalities that impair intestinal absorption, urinary bladder obstruction, or in patients who have undergone total or subtotal gastrectomy.

Dosage.—Azuresin is administered orally as a single test dose of approximately 2 Gm. in the form of granules. Patients should be instructed not to eat after midnight preceding the day of the test. On the morning of the test, the patient should empty the bladder and discard the urine. Breakfast is withheld until the test is completed. Two 250-mg. tablets of caffeine and sodium benzoate are swallowed with one glass of water. One hour later, the patient voids and saves this specimen in a jar marked "control urine." Then the 2-Gm. dose of the resin is stirred well and taken in one-fourth glass of water (without chewing the granules). If any granules remain in the glass, these are consumed with a little more water. Exactly two hours after the resin is taken, the urine should be voided and the entire amount saved in a jar marked "test urine." After the last specimen has been voided, the patient may eat breakfast. The two specimens should be delivered to the physician or to a clinical laboratory as soon as convenient. The patient may continue to pass blue or green urine for a few days.

When indicated or desired, a subcutaneous or intramuscular dose of 50 mg. of betazole hydrochloride for a person weighing 100 to 250 lb. (45.4 to 113.4 kg.) or 0.0275 mg. of histamine phosphate per kilogram of body weight may be substituted for the orally given caffeine and sodium benzoate as the stimulant to gastric secretion.

Preparations: granules 2 Gm. (with comparator, color standards, and two 250-mg. tablets of caffeine and sodium benzoate).

E. R. Squibb & Sons, Division of Olin Mathieson Chemical Corporation cooperated by furnishing scientific data to aid in the evaluation of azuresin.

CHEMICAL LABORATORY

The Chemical Laboratory has authorized publication of the following statement.

WALTER WOLMAN, PH.D., *Director.*

Monographs of tests and assays for new and nonofficial drugs adopted by the Chemical Laboratory of the American Medical Association represent an expression of opinion as to what might constitute adequate tests and assays to serve as a reference guide to those interested in the identity and quality of a new and nonofficial drug.

Completed monographs are published in the journal *Drug Standards* for those interested in the details of the procedures. Monographs on the following drugs have appeared in the March-April, 1959, issue of that journal, except for the monograph on chloroprocaine hydrochloride which appeared in the January-February, 1959, issue. The cooperation of the listed pharmaceutical firms that furnished samples and data is acknowledged.

Chloroprocaine hydrochloride	(Maltbie Laboratories)
Procyclidine hydrochloride	(Burroughs Wellcome & Co. [U. S. A.] Inc.)
Pyrrobutamine phosphate	(Eli Lilly & Company)

NEW AND NONOFFICIAL DRUGS

The following descriptions of drugs are based upon available evidence and do not in any case imply endorsement by the Council.

H. D. KAUTZ, M.D., *Secretary.*

Azuresin (Diagnex Blue).—Azure A Carbacrylic Resin.—A complex of azure A and a polyacrylic carboxylic acid resin. Azure A is a blue dye which is chemically defined as 3-amino-7-dimethylaminophenazathionium chloride.

Actions and Uses.—Azuresin, introduced in 1958, is employed as an indicator for the detection of gastric anacidity (achlorhydria) without intubation. After oral administration of the drug, the blue dye (azure A) in the resin is displaced by the hydrogen ions of free hydrochloric acid that may be present in the stomach. A part of the displaced azure A is absorbed and excreted in the urine within two hours after administration of the resin. A stimulant to gastric secretion is given one hour before administration of the resin. Urine voided during that hour serves as a control sample. The dye content of the urine specimen collected two hours after administration of the resin is visually estimated as an indication of the presence or absence of free hydrochloric acid in the stomach. Because visual estimation of a blue dye in the urine is much less complicated than determination of urinary quinine by photoelectric fluorophotometry, azuresin has completely replaced the older quinine carbacrylic resin for tubeless gastric analysis.

Azure A in the urine is estimated by use of the color comparator which is supplied with each test unit of the drug. Two color standards representing color intensities of 0.3 and 0.6 mg. of azure A in 300 cc. of solution (0.1 and 0.2 mg.%), respectively, are also provided. After dilution of the control urine sample and test urine sample to 300 cc. each, two 10-cc. aliquots of the control urine are placed in the comparator in front of the two standards and one 10-cc. aliquot of the test urine between the two controls. Visual comparison is then made between the color intensity of the two standards and a 10-cc. aliquot of the test urine. If the color of the test urine is darker than that of the 0.6-mg. standard, the patient is presumed to have secreted free gastric hydrochloric acid, and the test is complete at that point. Since azure A may be excreted in the urine in its blue form or a conjugated colorless form or both, the test should not be interpreted as negative (achlorhydria) until any colorless form present has been oxidized to the blue form. Thus, if the color of the test urine is lighter than that of the 0.6-mg. standard, all samples are acidified with two drops of 10% hydrochloric acid to give a pH between 2 and 4, heated for 10 minutes in a boiling water bath, and allowed to cool for two hours. If a red color results from the addition of hydrochloric acid, too much has been added and second aliquots must be used with less hydrochloric acid. It is important to allow the full two hours for cooling prior to rereading color intensities, since this period of time is required for the full color to develop. After the cooling period, visual color comparison between the test urine and the two standards is done as described previously. If the color intensity of the test urine lies between that of the 0.6-mg. and that of the 0.3-mg. standard, this is interpreted as presumptive evidence for hypochlorhydria. An intensity less than that of the 0.3-mg. standard is presumptive evidence for achlorhydria. A high degree of correlation has been obtained in tests for achlorhydria in which the azure A resin method and the conventional gastric analysis by intubation were used. It should be understood, however, that, when caffeine is used as the stimulant to gastric secretion prior to the administration of the resin, the azure A method determines what might be called a caffeine achlorhydria. True achlorhydria can be determined only if the most powerful stimulants to gastric secretion, such as betazole or histamine, are used.

The azuresin test does not furnish exact quantitative results. However, it is convenient for screening patients with minor gastric symptoms that are not considered sufficiently significant to warrant the discomfort of intubation gastric analysis or other more expensive diagnostic procedures. It *should not be used in lieu of more extensive examinations* whenever these are indicated. When the test indicates achlorhydria, some clinicians advocate confirmation of these results by repeating the test, using histamine or betazole as the stimulant to gastric secretion. The resin test method for achlorhydria is considered useful for the diagnosis of suspected cancer of the stomach, pernicious anemia, and gastric polyps.

Azuresin is of negligible toxicity, and, to date, no instances of drug idiosyncrasy have been reported (as was sometimes the case with the older quinine resin). The test may be carried out without regard to previous or concomitant drug therapy. *However, tubeless gastric analysis may be inaccurate* in the presence of pyloric obstruction, severe hepatic or renal disease, abnormalities that impair intestinal absorption, urinary bladder obstruction, or in patients who have undergone total or subtotal gastrectomy.

Dosage.—Azuresin is administered orally as a single test dose of approximately 2 Gm. in the form of granules. Patients should be instructed not to eat after midnight preceding the day of the test. On the morning of the test, the patient should empty the bladder and discard the urine. Breakfast is withheld until the test is completed. Two 250-mg. tablets of caffeine and sodium benzoate are swallowed with one glass of water. One hour later, the patient voids and saves this specimen in a jar marked "control urine." Then the 2-Gm. dose of the resin is stirred well and taken in one-fourth glass of water (without chewing the granules). If any granules remain in the glass, these are consumed with a little more water. Exactly two hours after the resin is taken, the urine should be voided and the entire amount saved in a jar marked "test urine." After the last specimen has been voided, the patient may eat breakfast. The two specimens should be delivered to the physician or to a clinical laboratory as soon as convenient. The patient may continue to pass blue or green urine for a few days.

When indicated or desired, a subcutaneous or intramuscular dose of 50 mg. of betazole hydrochloride for a person weighing 100 to 250 lb. (45.4 to 113.4 kg.) or 0.0275 mg. of histamine phosphate per kilogram of body weight may be substituted for the orally given caffeine and sodium benzoate as the stimulant to gastric secretion.

Preparations: granules 2 Gm. (with comparator, color standards, and two 250-mg. tablets of caffeine and sodium benzoate).

CLINICAL IMPORTANCE OF POTASSIUM

RENEWED interest has been stimulated in the element potassium. Evidence is accumulating that both hyperpotassemia and hypopotassemia are clinically significant disorders. Even the cardiotoxic property of potassium has a direct clinical application in the use of potassium citrate to induce complete, temporary arrest of the heart in surgery.[1]

Much that has long been known about potassium metabolism remained clinically inapplicable in the past because of the lack of good chemical methods to determine the concentration of potassium in body fluids and tissues. The first general facts about salt balance, about the harmful effects of deficiencies and excesses of potassium, and about its curious distribution between intracellular and extracellular fluids were obtained either by indirection or by difficult analytical methods. Since that time research in this field has been expedited by advances in chemistry. Advances in physics have likewise brought improved understanding of many other medical aspects of potassium, for example, its radioactivity, which was at one time considered as a possible cause of the spontaneous activity of the heart. It is not easy, today, to picture the difficulties, the confused concepts and inadequate apparatus, under which the early work on potassium was done. The advent of radioactive isotopes has made it possible to follow the movements of potassium atoms through biological structures, with results so rich as to be almost overwhelming, and the advent of the flame photometer, with related electronic apparatus, afforded a convenient, accurate method that all but revolutionized the study of potassium deficits or surfeits in body fluids and tissues.[2]

The kidneys, when healthy, are able to rid the body quite promptly of excesses of potassium that may enter by injection or ingestion. This fact is basic in clinical applications. When a heart is to be arrested for surgical purposes, potassium citrate is injected into the proximal aorta; it is kept there, and its action is confined to the coronary system, by the clamp on the aorta. When the heart is to be restarted after the operation, the first coronary sinus blood with its high potassium content is allowed to overflow from the heart, but the kidneys are relied on to dispose of whatever potassium gets into the general circulation.[1] In this situation, with healthy kidneys, the potassium is handled easily, but in other situations, if the kidneys are diseased, even small amounts of potassium can be fatal.[3] The concentration of potassium in normal plasma is given as 5 mEq. per liter (about 20 mg. per 100 cc.). Rising concentrations cause bradycardia, heart block, and finally (at about 20 mEq. per liter or 80 mg. per 100 cc.) cardiac arrest.

Conversely, however, it is also possible to deplete the body's store of potassium, 98% of which is stated to be intracellular.[4] There is reason to believe that potassium can be lost by way of diseased kidneys. Twelve renal or extrarenal conditions that may cause a potassium-losing nephritis have been listed by Mudge.[5] The extent and seriousness of the resulting derangements could be predicted from the immense literature on salt balance, membrane permeabilities, acid-base balance, erythrocyte activity, and axone physiology. The clinical manifestations of hypopotassemia were recognized by Aitken and colleagues in 1937.[6] Developments in adrenal physiology since then have led to recognition of aldosterone as an important hormone and of aldosteronism as a possible cause of hypopotassemia. A case reported by Alsted and Halberg [7] illustrates at once the difficulty and the importance of distinguishing between primary aldosteronism and primary renal hypopotassemia. It is necessary, in any case, to keep in mind the fact that potassium can be lost from the body by way of the kidney.

Potassium can also be lost by way of the intestine. Striking cases of hypopotassemia from this cause have been described by Roy and Ellis.[8] A 70-year-old man was found to be losing potassium as a result of a rectal adenoma. He had frequent voiding of copious watery feces. The rectal fluid had an extremely high potassium content (28 mEq. per liter). Recognition of the patient's potassium deficit explained his circulatory collapse and made it possible to prepare him adequately for surgery, so that he made an excellent recovery. The other case was that of a 56-year-old woman, who likewise had lost potassium by a watery discharge by rectum as a result of a tumor of the large intestine. Both a high potassium content of the discharge and a low concentration of potassium in her serum were established by chemical analysis. Recognition of the hypopotassemia again made it possible to treat her circulatory collapse successfully and to carry her safely through the necessary surgery.

The need of more refined diagnosis in cases of dehydration, acidosis, and salt imbalance is clearly revealed by such cases. Disturbances of potassium metabolism, as pointed out by Thorn and his colleagues in the instance of primary aldosteronism,[8] can be life-threatening. In some situations potassium medication will ameliorate symptoms; in others, it will aggravate them. Clearly such phrases as "saline solution," "isotonic salt solution," "physiological saline," and "Ringer's solution" impede progress by their inexactness and can cause real trouble in the clinic. The terms are not even qualitatively satisfactory. They do not indicate which saline compounds are to be used, whether they are to be isotonic with plasma or tears, or which of the various Ringer formulas is intended. Certainly the amount of potassium needs to be specified. Perhaps there is also a general need for short, precise ways of designating solutions to be given intravenously in adjusting a patient's water and electrolyte balance. In the meantime analytical chemists and electronic engineers might well continue their search for more accurate, quick, and less expensive methods of diagnosing the patient's requirements of sodium and potassium.

BIOCHEMISTRY AN AID TO PHYSICIANS

The rapid evolution of new diagnostic and therapeutic techniques is an obvious result of the ever-increasing rate of scientific research. Less obvious is the fact that some fundamentals of medical science are being transformed by the accumulation of biochemical knowledge, thus making understandable some previously incomprehensible biological phenomena. As long as 28 years ago, in an editorial, The Journal stated:

"Physiologic chemistry—or biochemistry, as it has been commonly designated more recently—has long since come of age. The subject has become an important and integral part of the study of medicine and the practice of the art. The special technic of biochemistry has been introduced into clinical diagnosis to such an extent that it competes in prominence with physical procedures and with bacteriologic and immunologic methods of examination and research."

In more recent years biochemistry has developed an importance which predicts that medical science in the future will be taught and applied still more widely in terms of biochemical events.

Medical science is entering a phase now in which many aspects of medicine, such as inborn errors of metabolism, intermediary metabolism, energy transfer, infection by bacteria and viruses, mental processes, gene and chromosome composition, and many others are being studied and interpreted at the molecular level. Some of the most intense study in biochemistry has been on the structure and function of enzymes and the interrelationships of the enzyme systems in the body processes. Knowledge in this field has increased to a stage where many of the balanced mechanisms of enzymatic body reactions are understood in stepwise detail.

These changes pose an important problem to practicing physicians. However difficult it may be to keep abreast of this new knowledge, it seems apparent that the practice of scientific medicine in the future will depend in large part on the realization of its impact. Despite the complexity of these newer relationships, their importance makes it desirable, at least, for physicians to attempt to gain insight into the current trends in medicine that are influenced by biochemistry.

The Journal believes that it can be of further help to physicians in calling attention to biochemical advances that are closely related to the practice of medicine. To this end there will be published at short intervals a series of editorials on this subject. The first one will appear in The Journal, August 8.

THE SECOND WORLD CONFERENCE ON MEDICAL EDUCATION

UNDER THE AUSPICES OF

THE WORLD MEDICAL ASSOCIATION

THEME: MEDICINE—A LIFELONG STUDY

Collaborating Organizations: The World Health Organization, Council for International Organizations of Medical Sciences, and International Association of Universities

WILL BE HELD AT

The Palmer House, Chicago, from
August 30 to September 4, 1959

Registration on Sunday, August 30, 1959

For details write: *The World Medical Association, 10 Columbus Circle, New York 19.*

THE PRESIDENT'S PAGE

A MONTHLY MESSAGE

In this, my first President's Page since taking office at the annual meeting last month in Atlantic City, I want to thank the entire profession for the many honors and courtesies shown me during my year as president-elect. I also want to pledge my utmost energy and dedication to the duties of the year ahead. My goal is to be a vigorous, articulate spokesman for the American Medical Association in these difficult, changing times.

One of our major problems today is the relationship between medicine and the various types of third parties involved in the organization, provision, and financing of medical services. Until last month we had no definitive policy on this complex subject. Now, as a result of the A. M. A. House of Delegates' action on the report of the Commission on Medical Care Plans, we do have a policy.

Contrary to some reports and interpretations, the House action in Atlantic City did not constitute a change in A. M. A. policy. Instead, it should be viewed as the first establishment of a broad policy which naturally will be subject to constant study, clarification, and revision in the years ahead.

In considering Part I of the Commission report, the House received all findings and conclusions as "information only." This means that statements in those parts of the report cannot be cited out of context as official A. M. A. policy. However, the House took definite action on the Commission's 39 recommendations, accepting 36 without change and rewording three others which involved miscellaneous and unclassified plans.

Probably the most significant action came on Recommendation B-16, which was changed to read:

"The American Medical Association believes that free choice of physician is the right of every individual and one which he should be free to exercise as he chooses. Each individual should be accorded the privilege to select and change his physician at will or to select his preferred system of medical care, and the American Medical Association vigorously supports the right of the individual to choose between these alternatives."

That, as I interpret it, reaffirms our fundamental faith in the principle of freedom of choice, but it also recognizes the patient's right to select the type of medical care plan he wants—including a closed panel plan.

The House also emphasized the "far-reaching significance" of Recommendation A-7, which says:

"'Free choice of physician' is an important factor in the provision of good medical care. In order that the principle of 'free choice of physician' be maintained and be fully implemented, the medical profession should discharge more vigorously its self-imposed responsibility for assuring the competency of physicians' services and their provision at a cost which people can afford."

In other words, if we are to give full meaning and value to the principle of freedom of choice, we must establish effective mechanisms to discipline that small minority of physicians whose actions bring discredit to the entire profession.

From the long-range point of view, some of the most important Commission recommendations are those urging increased activity by state and county medical societies and the A. M. A. in such areas as continuing study, better liaison, closer attention to legal and legislative factors, and development of guides for the relationships between medicine and the various types of third parties.

To implement A. M. A. activities, the House also approved a seven-point program for immediate attention by the Division of Socioeconomic Activities.

I urge every physician to study the Commission report and to support efforts to carry out the recommendations as adopted.

Louis M. Orr, M.D.
Orlando, Fla.

ORGANIZATION SECTION

LETTER REGARDING PUBLIC ASSISTANCE AND DISABILITY CLAIMS

Hon. Burr P. Harrison, Chairman
Subcommittee on Administration
of the Social Security Laws
Committee on Ways and Means
House of Representatives
Washington, D. C.

Dear Congressman Harrison:

This is in further reference to your letter of April 6, 1959, concerning the activities of the Subcommittee on Administration of the Social Security Laws, of which you are Chairman.

As I advised you on April 15th, the American Medical Association is very much interested in the assignment of your Subcommittee and is appreciative of the opportunity of supplying you with certain information.

The Association has for many years been interested in the Social Security Act and has worked closely with those charged with the administration of the programs established under the various sections of the statute. We have also, on numerous occasions, testified before committees of the House of Representatives and the Senate concerning proposed amendments to the Act.

Inasmuch as your Subcommittee's current primary interest is in the administrative complexities of the present law, I shall not dwell at any length on the views of the Association with respect to the numerous bills introduced in the 86th Congress which propose amendments of a medical nature to the Social Security Act. I would, however, respectfully invite your attention to the testimony presented by the Association to the House Ways and Means Committee on H.R. 9467 during the 85th Congress. A number of similar and identical bills have been introduced this year and are now pending before the House Ways and Means Committee.

The other item on this same subject to which I would invite your attention is the letter dated March 5, 1959, from Dr. Leonard Larson, the Chairman of the Board of Trustees of the American Medical Association, to the House Ways and Means Committee. I am enclosing copies of these two statements for your ready reference.

Although, as stated earlier, we have had a continuing interest in numerous provisions of the Social Security Act, our comments at this time are confined to the Public Assistance and the Old Age, Survivors and Disability Insurance programs.

As presently organized, the four Public Assistance programs are separate entities, independently financed. In the medical care programs for Public Assistance recipients, the states are more and more turning to "vendor payment" methods for at least a part of the medical, hospital and auxiliary services provided. As a result, Public Assistance recipients, under different programs in the same state, are frequently eligible for radically different levels of medical care.

The House of Delegates of the American Medical Association in December, 1958, recommended that the Social Security Act be amended "to permit states to combine the present four Public Assistance medical programs into a single medical program, administered by a single agency and making available uniformity of services to all eligible Public Assistance recipients in the state." The Association has made this recommendation because it believes that such a step would help to eliminate confusion, waste and duplication resulting from the present multiplicity of programs. The Association also believes that a uniform program would tend to promote higher quality medical care.

We would suggest, therefore, that your Subcommittee consider the advisability of studying the variation in the amount of expenditure for medical services under the several programs in the states, with a view to determining the relative effectiveness of combining these, at the state's prerogative, into a single Public Assistance medical program.

The Association, through its Committee on Indigent Care, has noted an insufficiency of statistics concerning the medical care provided under the Public Assistance program. Some states provide very general data on medical expenditures, some provide data as to the amount expended for each type of medical service; few, apparently, can provide details such as the cost per patient for each type of service, the specific illnesses or disabilities treated, the operations performed, or information as to which personnel or facilities provided the majority of these services. The value of good medical statistics which could be potentially available under the Public Assistance programs suggests that the Subcommittee might well study the possibility of encouraging more complete and uniform reporting by state agencies.

It is also noted that, at the Federal level, the medical staff of the Bureau of Public Assistance is extremely limited. In view of the growing importance of medical care under this program, as well as the confusion caused by recent legislative changes at the state level, the Subcommittee might also consider the question of whether the present staff is sufficient to provide adequate counselling to the states on changes in their individual programs. Consideration should also be given to the question of whether sufficient liaison has been maintained with the various professional organizations actually providing medical care. Since there are no physicians on the recently appointed Social Security Advisory Committee, it might be suggested that a special medical advisory committee be established.

Section 1002 (a) (10) of the Public Assistance provision of the law states, in part, that "in determining whether an individual is blind, there shall be an examination by a physician skilled in the diseases of the eye, or by an optometrist, whichever the individual may select." It is our suggestion that this section be amended by striking the words "or by an optometrist, whichever." We believe that to grant optometrists the right to make examinations for determining blindness can, in individual cases, result in a failure to ascertain the cause of blindness and thus prevent the administration of necessary medical rehabilitative care. The application of medical skills by a doctor of medicine will help insure the detection and successful treatment of the organism and systemic causes of blindness. Unfortunately for the patient, such diagnosis and treatment cannot be provided by optometrists.

The particular areas of concern to medicine in connection with the administration of this program, under Title II of the Act, are related to the evaluation of "disability" for OASDI claims and requests for information long after the doctor's examination.

In the first instance, the applicant for disability coverage is expected to pay the examining physician for the initial examination. Since many of these applicants are unable to pay, the physician frequently provides this service without charge. However, if the first examination is insufficient for the purposes of OASDI, the program may then pay a physician for consultation, or reexamination of the applicant. The Subcommittee might well study the confusion inherent in such a system, particularly since the reexamination is sometimes by the same physician who made the original examination.

In the second instance, cases are reported where the OASDI has requested medical data up to fifteen years after the physician encountered the case. Obviously, it is not reasonable to expect the physician's personal recollection or records to remain completely adequate over such a long period of time. The Subcommittee might wish to study the effects of such long-delayed requests for data on the over-all efficacy of the program.

If the American Medical Association can be of additional assistance in connection with the efforts of your Subcommittee, I hope that you will either call on me or on the staff of the Washington Office of the Association.

Sincerely yours,
F. J. L. Blasingame, M.D.
Executive Vice-president.

CONSULTANTS TO A. M. A. INSURANCE COMMITTEE

Ten persons, five of whom are physicians, have agreed to serve as consultants to the Committee on Insurance and Prepayment Plans of the Council on Medical Service. They are:

Richard J. Ackart, M.D., executive director, Virginia Medical Service Association, Virginia Hospital Service Association, Richmond, Va.
James P. Donelan, M.D., vice-president and medical director, Guarantee Mutual Life Insurance Co., Omaha
Mr. J. F. Follmann Jr., director of information and research, Health Insurance Association of America, New York City
Charles G. Hayden, M.D., executive director, Massachusetts Medical Service, Boston
H. Close Hesseltine, M.D., University of Chicago, Chicago
Mr. William Martin, Martin, Clearwater and Bell, New York City
Mr. John H. Miller, vice-president and senior actuary, Monarch Life Insurance Company, Springfield, Mass.
Mr. E. R. Paolini, vice-president–general manager, California Physicians' Service, San Francisco
Mr. James E. Stuart, executive vice-president, Blue Cross Association, New York City
Ennion S. Williams, M.D., vice-president and medical director, Life Insurance Company of Virginia, Richmond, Va.

With this added talent available on a consultant basis, the Committee and Council not only will be able to augment previous activities relating to health insurance and prepayment plans but also will be in a position to deal more effectively with other facets of insurance which involve the medical profession.

COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

REVISION OF ESSENTIALS OF APPROVED RESIDENCIES IN OTOLARYNGOLOGY

The following revision of the Essentials of Approved Residencies as they apply to Otolaryngology was approved by the House of Delegates at the Annual Session of the American Medical Association in June, 1959. These new Essentials replace Section II—Otolaryngology, on pages 28-29 of the Essentials of Approved Residencies, as revised to Dec. 5, 1958. **The reader's attention is directed particularly to the second paragraph under "Duration of Training."**

WALTER S. WIGGINS, M.D., *Secretary.*

II. Otolaryngology

Duration of Training.—Prior to July 1, 1960, residencies in otolaryngology which are designed to meet the requirements of the Council on Medical Education and Hospitals of the American Medical Association, the American College of Surgeons, and the American Board of Otolaryngology should include, after one year of internship, three years of progressive training in the specialty. One of these years may be spent in an approved residency in general surgery or medicine, or an additional year of rotating internship.

After July 1, 1960, residencies shall be of four years' duration, of which three must be progressive training in the specialty. The four years must include one year in an approved residency in general surgery, preferably before the special training. It is emphasized that the above are minimal requirements for certification and as a foundation for further development in the broad field of otolaryngology.

Scope of Training.—Residencies in otolaryngology should offer a broad training and should preferably include some experience in closely related fields of surgery. Adequate clinical and operative experience should be provided. Essential equipment for diagnosis and treatment should be available, including all special apparatus. The clinical material should be sufficient in variety and amount to provide adequate training in the various divisions of the specialty.

Adequate experience in bronchoesophagology, allergy, anesthesiology, maxillofacial surgery, and surgery of the neck, as they relate to otolaryngology, must be provided. The training shall include a systematic course of instruction with demonstrations on clinical and technical subjects pertinent to the various phases of otolaryngology.

As stated in the general requirements (Section 7, Part I), it is not essential, or even desirable, that all hospital residencies should adopt exactly the same program, or that they should offer a rigidly uniform sequence of experience. It is essential, however, that all hospitals participating in graduate training should be able to meet the fundamental requirements for an approved program and, either alone or in collaboration, should attain comparable results in the quality of training and in the experience obtained.

A program need not necessarily be confined to a single hospital. In programs involving two or more hospitals, it is essential that the training programs be organized by the parent hospital, with progressive responsibility for the residents. Collaborative programs can be developed where two hospitals of graduate training caliber have complementary clinical resources which can be combined to advantage in developing an acceptable program.

Application of Basic Medical Sciences.—There should be training in the applied anatomy of the ear, nose, throat, neck, chest, and esophagus, including the related nervous system. Applied microbiology, biochemistry, embryology, pathology, pharmacology, and physiology should be included and should be closely correlated with the clinical experience. Frequent departmental conferences for a detailed discussion of problem cases are important, as are also the clinicopathological conferences. The residents should study and discuss with the pathologist all tissues removed at operation, and all autopsy material from patients on their services. It is desirable to have the residents assigned for a period of service in the department of pathology.

Surgical anatomy should be stressed by the attending surgeons in discussing surgical cases with the residents, and also by the pathologist, as far as is possible, in the performing of autopsies. In addition, opportunity for the residents to work out special anatomic problems by performing regional dissections should, if possible, be provided.

Research offers an important opportunity for the application of the basic sciences in clinical problems. Reasonable facilities for research by the residents should be provided, together with stimulating guidance and supervision.

Surgical Staff.—The surgical staff should be composed of surgeons who are highly qualified in both surgical skill and judgment. It should be properly organized and harmonious, with the designated head or chief of service responsible for the quality of work done in the department. The position of chief of service should not be rotated as an honorary appointment, but should be held by the surgeon best fitted for this responsibility. The members of the staff should have a real interest in teaching and in the welfare of the residents, and must be willing to give the time and effort required by the educational program.

Clinical Material.—The hospital must be able to provide an adequate number and variety of surgical patients. Arbitrary figures cannot reveal these considerations accurately. Under ordinary circumstances, however, a general hospital, to support a residency in otolaryngology, should have annual admissions to that service numbering approximately 300 to 500 patients. The hospital must be able to provide an adequate number and variety of service cases. This is essential to give the progressive operative experience necessary for the resident. The residency program should be organized so that the residents will hold positions of increasing responsibility for the care and management of patients. The residents shall have sufficient operative experience to acquire surgical skill and judgment through the performance of surgical operations with a high degree of responsibility, but under circumstances providing adequate opportunity for consultation and advice.

An approved residency in otolaryngology should include a well-organized and well-supervised, active outpatient service.

A hospital which limits its clientele to special types of cases may, if otherwise qualified, be approved as a collaborating hospital if its residency is an integral part of an approved comprehensive program.

The provisions of the general requirements (Sections 1 to 9) must also be met for approval.

Residents who plan to seek certification by an American Board should communicate with the secretary of the appropriate board, as listed in Section V, to be certain regarding the full requirements for certification.

GOVERNMENT SERVICES

AIR FORCE

First Aid Training Kit.—The Gunter Air Force Base, Ala., branch of the School of Aviation Medicine has developed an inexpensive and simple training kit which will enable military or civilian nonmedical personnel to teach anyone the fundamentals of emergency medical care in one-third the time previously required. In announcing the development of the teaching kit, the Air Force surgeon general said that the kit had simplified the teaching of basic emergency medical care to the point where practically anyone who can read may now teach others emergency medical care in the field. The teaching kit covers the basic emergency field treatment of radiation exposure, shock, cuts, wounds, burns, and movement of injured persons. It weighs only 75 lb. and probably could be mass produced at an estimated cost of less than $100 each.

Personal.—Major Gen. Olin F. McIlnay, deputy surgeon general of the United States Air Force, will retire on July 31 after more than 30 years active military service and Brig. Gen. John K. Cullen, U. S. A. F., M. C., will become Deputy Surgeon General of the United States Air Force.—Col. Raymond T. Jenkins, U. S. A. F., M. C., will become director of plans and hospitalization in the office of the surgeon general on Aug. 1 and Col. Herbert H. Kerr, U. S. A. F., M. C., will become deputy director of plans and hospitalization. Col. George H. Kojac, U. S. A. F., M. C., will replace him as chief of the plans and operations division.—Col. Charles H. Morhouse, Fifth Air Force surgeon, was appointed to the rank of brigadier general.

ARMY

Personal.—A commendation ribbon with metal pendant was awarded to Col. Arthur J. Carbonell for service as commanding officer and surgeon of the Patterson Army Hospital at Fort Monmouth. Having completed his tour of duty at that station, Colonel Carbonell has been assigned as surgeon of the VII Corps in Germany.

NAVY

Personal.—In June Rear Adm. Edward C. Kenney, M. C., U. S. N., was made deputy and assistant chief of the bureau of medicine and surgery. He succeeded Rear Adm. Bruce E. Bradley, M. C., U. S. N., who became commanding officer of the National Naval Medical Center, Bethesda, Md.—Capt. Gerald J. Duffner, M. C., U. S. N., reported to the bureau of medicine and surgery for duty as director, submarine medicine division.

VETERANS ADMINISTRATION

Personal.—Dr. Granville A. Bennett, dean of the University of Illinois College of Medicine, was appointed to the Veterans Administration advisory committee on education as a replacement for Dr. John B. Youmans, former dean of Vanderbilt University Medical School, who resigned his committee membership on accepting appointment as technical director of research at the Army Medical Research and Development Command in Washington, D. C. This five-man committee of medical educators meets at least once yearly in Washington, D. C., to advise the VA chief medical director on matters pertaining to conduct of the VA medical education program and on medical school deans committee-VA relationships.—The Veterans Administration chief medical director's commendation, highest award given by the VA department of medicine and surgery, was presented to Dr. Edwin W. Straus of the agency's Lexington, Ky., hospital. Dr. Straus was cited for his outstanding contributions to the VA patient care and medical research programs and for his studies of chemotherapy in psychiatry.

PUBLIC HEALTH SERVICE

Personal.—The National Cancer Institute's Board of Scientific Counselors, established in November, 1957, consists of six outstanding nonfederal scientists who periodically make recommendations concerning the research conducted by the National Cancer Institute. On July 1, Dr. Phillip P. Cohen of the University of Wisconsin became chairman of the board, succeeding Dr. Wendell Stanley of the University of California, who remains on the board as a member. Dr. Jacob Furth, Children's Cancer Research Foundation, Boston; Dr. Hugh Roland Butt, Mayo Foundation, Rochester, Minn.; and Dr. J. Englebert Dunphy, University of Oregon Medical School, Portland, also became members of the board in July.

Health Statistics.—Not counting military personnel or civilians in mental or other long-term institutions, the American people had, all told, about 24 million impairments in the period July, 1957, through June, 1958. These impairments included such chronic or permanent defects as paralysis, deformity, and total or partial loss of hearing and vision. The rate of impairment was 141.4 per 1,000 persons in the civilian, noninstitutional population. The report does not show the total number of persons with impairments, since many people, particularly older people, have more than one impairment. Blindness, defined as the inability to read ordinary newsprint even with the help of glasses, was reported for an estimated 960,000 people, a rate of 5.7 per 1,000 persons. In addition, 2,064,000 people were reported to have visual impairments less severe than blindness, the rate being 12.3 per 1,000. About 109,000 persons were reported as totally deaf, a rate of 0.6 per 1,000 persons; and other hearing impairments affected 5,714,000 persons, a rate of 33.9 per 1,000. Of all impairments, 33% were caused by injury. The impairments with the highest percentage rate due to injury were loss or defects of extremities. The types least often due to injury were speech defects and blindness. Impairments increased with advancing age from 52.9 per 1,000 persons at ages under 25, to 615.0 per 1,000 at ages 75 and over. Of all impairments reported, 82.2% of the patients had been attended by a physician at some time. The new report is entitled "Impairments, by Type, Sex, and Age, United States, July 1957—June 1958," Public Health Service publication no. 584-B9. Copies are for sale by the Superintendent of Documents, Government Printing Office, Washington 25, D. C., at 25 cents a copy.

FOOD AND DRUG ADMINISTRATION

Chewing Gum Won't Slim You.—The Food and Drug Administration seized 90,000 chewing gum tablets offered as a "no-diet" reducing treatment at $1 for a 20-tablet bottle. The product was alleged to be misbranded in that false representations were contained in the labeling and in sales promotion materials. These included a display carton and card, box label and insert, and a newspaper mat and tear sheet entitled "Eat What You Want—Yet Lose Up to 3-5-9 Pounds A Week," and a tear sheet entitled "Eat What You Want—Yet Lose Pounds and Inches Fast."

Seaweed Debunked.—Since eating seaweed will not assure good health, the Food and Drug Administration seized 65,000 5-grain tablets of "Pure Pacific Sea Kelp" promoted with cure-all claims at $4.50 per bottle of 1,000 tablets. The Kingsport, Tenn., dealer bought the tablets in bulk; repackaged and relabeled them in his name, and prepared promotional leaflets entitled "Are You Starving?" and "Food and Your Body." The FDA alleged that it was misbranding in that the tablets were falsely claimed to furnish adequate amounts and proportions of all the minerals, trace elements, and basic materials necessary to life, and for proper nourishment and good health. Seaweed is a source of iodine, already supplied adequately in the diet in iodized salt, and a single 5-grain kelp tablet unnecessarily supplies 58 times the minimum daily requirement for iodine. There is no general need for supplementing the diet with manganese, copper, alginic acid, chlorophyll, mannitol, or zinc—all offered as essential nutrients on the product label. The dealer claimed the tablets would produce will power, vigor, and stamina; coagulate blood in wounds; prevent tuberculosis, rickets, and excessive weight; distribute hormones in the body; stimulate memory; harden bones and teeth; build brain and nerves; maintain normal heartbeat; and prevent hardening of the arteries and cataracts.

MEDICAL NEWS

ARKANSAS

Dr. Rhine Honored.—Hundreds of friends honored Dr. Thomas E. Rhine recently at the anniversary celebration of the 60th year of his practice in Thornton. Dr. Rhine, 83, who spent the first year of his practice at Locust Bayou before coming to Thornton, has reportedly delivered 10 children and 57 grandchildren of a woman whom he had also delivered.

CALIFORNIA

Grants for Cardiovascular Studies.—The Los Angeles County Heart Association announced the award of $199,783.75 to investigators working at local medical research centers for the study of cardiovascular diseases, effective July 1. Dr. Mitchel D. Covel, Research Committee chairman, said the awards are for work to be performed during the next 12 months. Included in the grants are funds for support of the association's Cardiovascular Research Laboratory at UCLA, two established investigators, four research fellows, and 16 grants-in-aid. An additional $15,000 in awards will be made by the Long Beach Heart Association to investigators working at hospitals there.

COLORADO

New Faculty Members.—The appointment of three new full-time members of the faculty was announced by Dr. Robert J. Glaser, dean of the University of Colorado School of Medicine, Denver. The three are all graduates of Harvard Medical School, Boston. Named professor and head of the department of radiology is Dr. David M. Gould, who currently occupies a similar position at the University of Arkansas Medical Center, Little Rock. He succeeds the late Dr. Raymond R. Lanier, who was fatally injured in an automobile accident while hunting in northeastern Colorado last fall. Appointed professor and head of the department of pathology is Dr. Morgan Berthrong, pathologist at the Glockner–Penrose Hospital in Colorado Springs since 1954. He succeeds Dr. James B. McNaught, who voluntarily stepped down as department head, a position he has occupied since August, 1945. Dr. McNaught, who has headed the American Board of Pathology, will remain on the faculty, as a professor of pathology. Dr. Conrad M. Riley, associate professor of pediatrics, Columbia University College of Physicians and Surgeons, New York City, will serve as full-time chief of Pediatric Service at Denver General Hospital, with the rank of professor of pediatrics at the C. U. School of Medicine.

ILLINOIS

Chicago

Sports Medicine Congress at Pan American Games.—A Sports Medicine Congress will be held in conjunction with the third Pan American Games, scheduled for Chicago Aug. 27-Sept. 7. The congress will meet on the Chicago campus of Northwestern University Sept. 1-2, and will feature experts in athletic training, care of injuries, diet, cardiovascular effects of sports activity, and other facets of the sports medicine field. Dr. Theodore R. Van Dellen is general chairman of the congress. Dr. Paul Dudley White, Boston, will be the featured speaker at the first plenary session Sept. 1. On Sept. 2, Dr. Allan J. Ryan, Meridian, Conn., will be the speaker. All sessions of the congress will be open to persons interested in the field of sports medicine. Information can be obtained from Dr. Van Dellen at Pan American Games, Inc., 310 S. Michigan Ave., Chicago 4.

Society News.—At the annual meeting of the Chicago Neurological Society held May 12, the following officers were elected: president, Dr. Meyer Brown; vice-president, Dr. Vladimir G. Urse; secretary, Dr. Ernst Haase; and councilor, Dr. John J. Madden.——At the annual meeting of the Metropolitan Dermatological Society of Chicago May 13 the following officers were elected: Dr. Theodore K. Lawless, president; Dr. John A. Guerrieri, vice-president; and Dr. Tibor Benedek, secretary-treasurer.

Hospital News.—Dr. Emil D. W. Hauser, associate professor of orthopedic surgery, Northwestern University Medical School, was installed as president of the medical staff of Passavant Memorial Hospital at the staff's annual meeting. He succeeds Dr. Clifford J. Barborka. Dr. Hauser has been associated with Passavant since he joined the Northwestern faculty in 1930.——The Grant Hospital of Chicago announced the inauguration of a full program of progressive patient care, with the organization of hospital facilities, services, and staff centered around the medical and nursing needs of the patients. An intensive care unit is designed for critically ill and post-operative patients, the intermediate

---

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. Programs should be received at least three weeks before the date of meeting.

care unit for patients needing standard care, and the self-care unit for ambulatory patients.—Dr. George J. Rukstinat was elected president of the medical staff of Holy Cross Hospital at its recent annual business meeting. Dr. Rukstinat succeeds Dr. Edward J. Krol, who served as president for the past two years.

MASSACHUSETTS

Civil War Mortar Explodes.—The Springfield *Republican* for June 7, reported that Marine Sergeant Ernest Castro, of Russell, lost both arms when a Civil War mortar exploded at Eastover. The sergeant and a resort owner had fired the old weapon earlier as part of an entertainment program. The mortar misfired during a second attempt.

Dr. Schall Retires.—Dr. LeRoy A. Schall will retire from Harvard University Aug. 31, to become Walter A. LeCompte Professor of Otology and Professor of Laryngology, Emeritus. Simultaneously, Dr. Schall will retire as chief of otology and laryngology at the Massachusetts Eye and Ear Infirmary and the Massachusetts General Hospital. Dr. Schall has served the hospitals for 36 years and the Harvard Medical School for 20 years.

Personal.—Dr. C. Sidney Burwell, on Aug. 31, will become Levine Professor of Medicine, Emeritus, at Harvard, bringing to a close 40 active years of academic life. Simultaneously, he will retire as physician to the Peter Bent Brigham Hospital and as visiting physician at the Boston Lying-in-Hospital. Following his official retirement, Dr. Burwell plans to occupy an office in the Administration Building of the Medical School, where he will engage in writing the history of the Harvard Medical School. —Dr. James M. Faulkner, of Brookline, medical director, Massachusetts Institute of Technology, was elected chairman of the Joint Administrative Board of the newly formed Boston University–Massachusetts Memorial Hospitals Medical Center.

Dr. Fitzpatrick Named Wigglesworth Professor.—Dr. Thomas B. Fitzpatrick, Portland, Oregon, was appointed Edward Wigglesworth Professor of Dermatology and head of the department at Harvard Medical School, Boston. He will serve simultaneously as chief of the dermatological service at the Massachusetts General Hospital. Dr. Fitzpatrick has been on leave-of-absence at Oxford University, England, from his post as Head of the Division of Dermatology at the University of Oregon.

MICHIGAN

Society News.—The following officers were elected to serve the Western Michigan Pediatric Society during the fiscal year 1959-1960: president, Dr. Clarence L. Hoogerland, Alma; president-elect, Dr. Sprigg Jacob, Lansing; secretary-treasurer, Dr. Jerome E. Webber, Grand Rapids; and assistant secretary-treasurer, Dr. Marshall J. Feeley, Benton Harbor.—Dr. John W. Rebuck, is the president-elect of the Michigan Pathological Society. Dr. Albert F. De Groat, director of the pathology department at Herman Kiefer Hospital, is president of the society for 1959. Dr. Viola G. Brekke, pathologist for Highland Park General Hospital, remains in her capacity of secretary-treasurer.

NEW YORK

Dr. Gillies Named Division Chairman.—Dr. Alastair J. Gillies, of New Haven, Conn., became professor of anesthesiology and chairman of the Division of Anesthesiology, University of Rochester Medical Center, in July succeeding Dr. David V. Thomas. Dr. Gillies also will be anesthetist-in-chief. Since 1955, Dr. Gillies has been at the Yale University School of Medicine as assistant professor of anesthesiology and associate director of the department of anesthesia in the Grance–New Haven Community Hospital in New Haven.

Society News.—At the May 16 meeting of the Northeastern New York Radiological Society the following officers were elected for 1959-1960: president, Dr. Sidney I. Etkin, Albany; vice-president, Dr. Everett A. Jacobs, Hudson; and secretary-treasurer, Dr. Irving VanWoert Jr., Albany.—The New York Roentgen Society has appointed the following officers for the coming year: president, Dr. Harold G. Jacobson; vice-president, Dr. Frank J. Borrelli; secretary, Dr. William B. Seaman; treasurer, Dr. Albert A. Dunn; and member of executive committee, Dr. John A. Evans. All are from New York City.

New York City

Dr. Breinin Appointed Department Chairman.—Dr. Goodwin M. Breinin was appointed professor and chairman of the department of ophthalmology, New York University–Bellevue Medical Center. He was also appointed director of the eye services of University and Bellevue hospitals and consultant to the New York Veterans Administration Hospital. He succeeded Dr. Arthur G. DeVoe, who became chairman of the department of ophthalmology at Columbia University College of Physicians and Surgeons. Dr. Breinin is the first incumbent of the Daniel B. Kirby professorship of research ophthalmology at the Medical Center and he will continue to hold that professorship. In 1959 he was the recipient of the Edward Lorenzo Holmes Award of the Institute of Medicine of Chicago.

Personal.—Dr. Harry E. Ungerleider, cardiologist, was appointed consulting medical director of North American Reassurance Company. Dr. Ungerleider since 1947 had been medical director of research of The Equitable Life Assurance Society of the United

States.—Dr. Paul Klemperer, retired director, department of pathology, Mount Sinai Hospital, received on June 12 an honorary doctor of science degree at the University of Chicago with the following citation: "Devoted scholar and inspiring teacher whose discerning observations and penetrating comprehension have led to great progress in the understanding of rheumatic disease."—George T. Mills, Ph.D., of Glasgow, Scotland, was named associate professor in the department of medicine, at the State University of New York Downstate Medical Center, Brooklyn. Evelyn E. B. Smith, Ph.D., who has been working in the department of biochemistry at the University of Glasgow as a senior fellow of the Carnegie Institution of Washington was named to the post of assistant professor of medicine.

NORTH CAROLINA

Training for Medical Secretaries.—A new training program in medical secretarial work began July 1 at the Duke University Medical Center, Durham. The one-year program will combine classroom study with supervised on-the-job training. A pilot group of four students will be trained during the first year and present plans call for increasing this number to eight in 1960-1961. Participants will do classroom work in medical terminology, public relations, and general office practices. Their on-the-job training will be supervised by Duke medical secretarial personnel. Entrance requirements for the program include two years of post-high school secretarial training, either in college or business school. Students will receive a small salary to be applied toward living expenses, and certificates will be awarded upon successful completion of the program.

OHIO

Dr. Sabin Receives Science Award.—Dr. Albert B. Sabin, professor of research pediatrics, University of Cincinnati College of Medicine, on June 29 was presented with the Howard Taylor Ricketts Award of the University of Chicago "for a basic contribution to science." The presentation was made by Dr. Lowell T. Coggeshall, dean of the division of biological sciences at the university. Dr. Sabin spoke to a medical audience on the present status of the oral vaccine which he has developed. The vaccine is being used for inoculations in Russia, and mass use of the vaccine also has taken place in Mexico, Singapore, and European countries.

Fellowships for Heart Research.—Applications for heart research fellowships at Central Ohio institutions are being accepted by the Central Ohio Heart Association. To qualify, an applicant must hold a doctor's degree from an approved medical or graduate school and have served one year of internship or the equivalent. In exceptional cases, a fellowship may be awarded to an individual with a bachelor's or master's degree who has demonstrated "unusual promise." Qualified nonmedical personnel will be given equal consideration provided their projects are related to cardiology. Both clinical and basic science fellowships will be awarded for one year at an annual stipend ranging from $2,800 to $8,000. Fellows will spend full time in their research and associated studied, and clinical fellows will not be permitted to have responsibility for the care or treatment of patients, participate in resident rotation, or render hospital services customarily performed by residents. A fellow may pursue part-time studies toward a graduate degree, with prior approval of all concerned. An applicant should have a definite research program in mind, and it must be a project of which he is the senior author and is primarily responsible. He should obtain approval and make plans with an investigator under whom he is to work. The Donald Mahanna Fellowship will be awarded to an individual with an M.D. or Ph.D. who has established himself in research. It will be awarded at the discretion of the association's Fellowship Committee only when there is a candidate with "suitably superior qualifications." All applications must be postmarked not later than Sept. 15. Notification of action will be made by Dec. 1 for fellowships starting July 1, 1960. Requests for application forms should be directed to the Central Ohio Heart Association, 50 E. Broad St., Columbus 15, Ohio.

PENNSYLVANIA

Philadelphia

University News.—The senior class of the Temple University School of Medicine presented a portrait of Dr. W. Emory Burnett, chairman, department of surgery, to the Medical School. Presentation remarks by President Robert L. Johnson and an address by Dr. I. S. Ravdin, John Rhea Barton Professor of Surgery at the University of Pennsylvania, highlighted the event.—At the annual meeting of the members of the Philadelphia College of Pharmacy and Science March 23, Ivor Griffith, Ph.D., was reelected president for the 19th consecutive year. He remains as dean of the faculty, an office he has held since 1937.

WYOMING

Dedicate Rehabilitation Center.—Dedication of the new 2-million-dollar Gottsche Rehabilitation Center and Hot Springs County Memorial Hospital at Thermopolis was held June 27. Principal speaker was Dr. Frank H. Krusen, of Mayo Clinic, Rochester, Minn., who discussed "The Future of Physical Medicine and Rehabilitation." Introductory remarks were made by Mr. Charles M. Smith, Thermopolis, president of the Gottsche Foundation. Former Wyoming Governor Milward Simpson, of Cody, director of the foundation, presided at the dedication. Other speakers were Wyoming Governor J. J. Hickey; Dr. Benjamin Gitlitz, Thermopolis, president of the Wyoming State Medical Society; Mr. J. O. Spangler, Greybull, representing the Elks Lodge; and Dr. Charles H. Flint, executive director of the Gottsche Rehabilitation Center. A fund for the construction of this medical center was started in 1954. As a result of the death of their daughter, Marguerite, from poliomyelitis, William H. and Carrie Gottsche of Rock Springs, Wyo., resolved that there would be a place in the state of Wyoming to care for other persons so afflicted. Thermopolis was selected as the site. The Gottsche Foundation, a Wyoming corporation with the purpose of rehabilitation of handicapped persons, was started in a trust set up by the Gottsche family. The board decided on a plan for a combined county hospital and rehabilitation center and this plan was submitted to the voters of Hot Springs County. The hospital unit is complete with operating rooms for emergency and elective surgical procedures. In all there will be 54 beds for surgical, medical, and chronically disabled patients. The Rehabilitation Center has six treatment booths for physical therapy, two gymnasiums, occupational therapy facilities for partially disabled persons, domiciliary care units for 24 children and two housemothers, classrooms, and speech-therapy and other facilities. The Wyoming Society for Crippled Children and Adults will occupy quarters in the center.

Personal.—Dr. James W. Sampson, of Sheridan, was appointed by the Wyoming State Board of Health as director of the Department of Public Health July 1, succeeding Dr. Franklin D. Yoder, who has become director of the Division of Socio-Economic Activities of the American Medical Association.

GENERAL

Cardiology Meeting in Philadelphia.—The American College of Cardiology will hold its eighth interim meeting at the Benjamin Franklin Hotel, Philadelphia, Oct. 23-25, according to Dr. Gabriel F. Greco, Ozone Park, N. Y., member of the publication committee. This year for the first time the scientific sessions of the college will be concurrent with the 32nd annual meeting of the American Heart Association and will include a joint program. The college will conduct fireside conferences on the evening of Oct. 23, in which A. H. A. members will participate jointly. On Oct. 25, a panel on cardiac resuscitation will be presented jointly by the college and the association's council on clinical cardiology. Programs may be obtained from Dr. Philip Reichert, executive director, A. C. C., Empire State Building, New York City.

Postgraduate Medical Cruise.—The New York State Academy of General Practice will sponsor a scientific cruise to the West Indies Oct. 22-Nov. 4, aboard the liner Kungsholm, of the Swedish American Line. The scientific program will include an intensive course on hypnosis covering the use of hypnosis in general practice, anesthesiology, obstetrics and gynecology, and other medical specialties. Instruction will include practical applications in the field of general practice. The second section of the program will include selected topics in metabolism and endocrinology and the faculty will be drawn from the Albany Medical College under supervision of Dr. Frank M. Woolsey Jr., associate dean and director of postgraduate education, Albany Medical College. The program is acceptable for 18 hours of category I credit. There is no registration fee. For information, write Dr. Seymour Fiske, Chairman, Post Convention Cruise Committee, 150 E. 71st St., New York 21.

Professor Erich Hoffmann Dies.—Prof. Erich Hoffmann, an honorary member of the American Medical Association, who was associated with F. R. Schaudinn in the discovery of *Treponema pallidum,* died in Bonn, Germany, May 13, soon after celebrating his 91st birthday. Born on April 25, 1868, Professor Hoffmann was educated at Kaiser Wilhelm Academy, Berlin. He graduated in medicine in 1892, entered army medical services in 1893, and five years later became a staff officer of the Military Medical Academy in Berlin. In 1900 he obtained an appointment under Edmund Lesser in Berlin, and began to specialize in dermatology and syphilology. In 1908, Professor Hoffmann was appointed to a teaching post at the university clinic for skin diseases in Halle becoming its director a year later. In 1910 he was appointed director of the university skin clinic in Bonn and was promoted to the chair in 1918. He retired in 1934 but continued his researches for some years afterwards.

Guide for Hospital Training Programs.—"Staphylococcal Disease: Guide for Organizing Hospital In-Service Training Programs" has been produced by the U. S. Public Health Service's Communicable Disease Center, Atlanta, Ga., and is available to assist hospitals in the control of hospital-acquired staphylococcal infections. The guide was developed as a result of a recommendation of the National Conference on Hospital-Acquired Staphylococcal Disease in September, 1958, that educational programs be held by hospital infections committees for all hospital personnel. It is based on the experience acquired by the Communicable Disease Center since that time in assisting hospitals to develop such training activities. The guide has been approved by the American Hospital Association. Single copies will be distributed to state and local health departments and to more than 6,000 hospitals throughout the country. Additional copies may be obtained from the Superintendent of Documents, U. S. Government Printing Office, Washington 25, D. C., at a charge of 30 cents each.

Physical Impairments.—The *Science News Letter* for June 27 has reported that Americans suffer from "impairments"—deafness, blindness, speech defects, cerebral palsy, and loss or absence of hands and feet—at a rate of some 141 per 1,000. This is a total of 24,000,000 impairments. Almost six Americans in 1,000 cannot read a story in an ordinary newspaper, even with the help of glasses. Another 2,000,000 Americans, more than 12 per 1,000, have visual impairments less severe than blindness. About one person in 2,000 is totally deaf, while other hearing impairments affect some 33.9 Americans in 1,000. This report, from a series on the nation's health published by the Public Health Service, points to the increasing number of older persons with impairments of some kind. In persons 75 years old or older these defects were about 12 times greater than the number found in persons under 25 years of age. Servicemen and persons in mental and other long-term institutions were not included in the survey which covered the period July, 1957, through June, 1958.

Director for Committee of World Association.—At the 12th annual meeting of the board of directors, World Medical Association, United States Committee, Inc., Mr. Henry S. McNeil, president of McNeil Laboratories, Inc., was unanimously elected to serve as a director for the term 1959-1962. The board of directors established an "Honorary Board Membership" classification for which members of the board "who have served diligently and have made distinguished contributions to the activities of the United States Committee" are eligible for election. Mr. Robert Lincoln McNeil, chairman of the board, McNeil Laboratories Inc., a member of the Board of Directors, World Medical Association, United States Committee, Inc., since its organization in 1948, was unanimously elected the first Honorary Board Member. The following were reelected officers of the board for 1959-1960: chairman, Dr. Austin Smith, president, Pharmaceutical Manufacturers Association; vice-chairman, Mr. H. J. Loynd, president, Parke Davis & Company; and secretary-treasurer, Dr. Louis H. Bauer, Secretary General, World Medical Association.

Council on Youth Fitness.—The third annual meeting of the President's Council on Youth Fitness with the President's Citizens Advisory Committee on the Fitness of American Youth will be held Sept. 13-15, at the United States Air Force Academy, Colorado Springs, Colo., Secretary of the Interior Fred A. Seaton, chairman of the council, announced. The President's Council on Youth Fitness is composed of seven Cabinet members (Interior; Defense; Agriculture; Commerce; Labor; Health, Education, and Welfare; and Housing and Home Finance Agency) charged with the responsibility of promoting the "efficacy of existing programs and the launching of additional programs which will enhance the fitness of American youth." The council seeks to "coordinate, stimulate, and improve not only the functions of federal agencies with respect to the fitness of youth, but chiefly to encourage the extension and implementation of existing local community programs by making maximum use of all facilities and organizations already in existence." The first annual meeting of the council and the advisory committee was held at the United States Military Academy, West Point, N. Y., September, 1957.

Portuguese Physician Awarded Fellowship.—The creation of the Pfizer Fellowship in Physical Medicine and Rehabilitation for a Portuguese physician to undertake postgraduate training in the United States was announced simultaneously in Lisbon and New York. The announcement in Lisbon was made by the American Ambassador of the United States to Portugal, the Hon. C. Burke Albrick. In New York, the announcement was made by Dr. Howard A. Rusk, president, World Rehabilitation Fund, Inc. The fellowship will provide a three-year period of training in physical medicine and rehabilitation for a physician from Portugal. Ambassador Albrick announced that Dr. Maria da Graca de Campos Andrada, of Lisbon, has been selected by the World Rehabilitation Fund as the Pfizer Fellow. Dr. Andrada will begin her training program in the United States at the Institute of Physical Medicine and Rehabilitation, New York University–Bellevue Medical Center, in July. The fellowship was made possible by a contribution to the World Rehabilitation Fund by Chas. Pfizer & Co., Inc. The fellowship will be administered by the World Rehabilitation Fund, an American voluntary organization, in cooperation with the International Society for the Welfare of Cripples.

Meeting on Biological Photography.—Newly developed uses of medical and scientific photography will be keynoted at the 1959 annual meeting of the Biological Photographic Association, to take place Aug. 31-Sept. 3 at the Sheraton Mount Royal Hotel in Montreal. This marks the first time the association will hold its annual meeting outside the United States since it was founded at Yale University in 1931. Speakers during the four-day program will describe research and administrative developments in the use of photography and motion pictures at their particular medical and dental schools, hospitals, research institutions, or science centers. Winners of the distinguished annual awards of the association will be announced in the photographic categories of clinical photography, gross specimens, photomicrographs, photomacrographs, and natural science. Motion picture awards will be announced in the categories of professional, institutional, and sequence films. Color and monochrome entries will be on display throughout the meeting, and motion pictures will also be programmed. The Biological

Photographic Association, dedicated to the skills of medical and scientific photography, has a worldwide membership which includes physicians, medical editors, educators in the fields of medicine and science, and staff photographers of medical and scientific institutions.

Surgeons to Meet in Chicago.—The 24th annual congress of the North American Federation, International College of Surgeons, will be held in the Palmer House, Chicago, Sept. 13-17. The North American Federation covers the United States, Canada, Mexico, Cuba, Haiti, Guatemala, Honduras, El Salvador, Nicaragua, Costa Rica, and Panama. Dr. Karl A. Meyer, of Chicago, and Dr. W. Wayne Babcock, of Philadelphia, have been named honorary chairmen of the congress, and Dr. Alexander Brunschwig, of New York City, has been chosen general chairman. Surgical specialties to be represented are: coloproctologic, neurologic, obstetric and gynecologic, ophthalmologic, otorhinolaryngologic, orthopedic, plastic and reconstructive, traumatic and rehabilitation, and urologic. There will be surgical motion pictures, reports on advances in military medicine, and a surgical nurses' program. The congress will be held in honor of the Chicago Medical Society and in memory of Drs. John B. Murphy, Christian Fenger, and Nicholas Senn, Chicago pioneers in surgery. Dr. Edward L. Compere, of Chicago, is president of the United States Section and secretary of the North American Federation, and Dr. Ross T. McIntire, of Chicago, is executive director of the College. Surgeons desiring to present papers should write to Dr. Peter A. Rosi, International College of Surgeons, 1516 Lake Shore Drive, Chicago 10.

Society News.—At the 12th annual meeting of the board of directors of the **World Medical Association, United States Committee, Inc.**, Mr. Henry S. McNeil, president of McNeil Laboratories, Inc., was unanimously elected to serve as a director for the term 1959-1962. The following were reelected officers of the board for 1959-1960: chairman, Dr. Austin E. Smith, president, Pharmaceutical Manufacturers Association; vice-chairman, Mr. Harry J. Loynd, president, Parke Davis & Company; and secretary-treasurer, Dr. Louis H. Bauer, secretary general, World Medical Association.——At the annual meeting of the **American Radium Society** the following officers were elected for the year 1959-1960: president, Dr. Theodore R. Miller, New York City; president-elect, Dr. Jesshill Love, Louisville, Ky.; first vice-president, Dr. Gray H. Twombly, New York City; second vice-president, Dr. Leonidas D. Marinelli, Chicago; secretary, Dr. Robert L. Brown, Emory University, Ga.; and treasurer, Dr. Gilbert H. Fletcher, Houston, Texas. The 42nd annual meeting will be held at the Caribe Hilton, San Juan, Puerto Rico, March 17-19, 1960.——Dr. Booker T. Holmes, Frankfort, Ky., was named president-elect of the **John A. Andrew Clinical Society.** Dr. John W. Chenault, Bradenton, Fla., will serve as president for 1960, succeeding Dr. James D. Merida, Cleveland. Dr. Eugene H. Dibble Jr. was reelected secretary and Mr. Louis A. Rabb was elected treasurer.

Prevalence of Poliomyelitis.—According to the National Office of Vital Statistics, the following number of reported cases of poliomyelitis occurred in the United States, its territories and possessions in the weeks ended as indicated:

Decrease in Marriages.—Marriages in the United States decreased by about 4% in 1958, the second straight year of decline, it is reported by statisticians of the Metropolitan Life Insurance Company. The actual number of marriages during the year was about 1,456,000 compared with 1,518,000 in 1957 and 1,585,000 in 1956. The 1958 marriage rate—8.4 per 1,000 population, including Armed Forces overseas—was the lowest recorded since 1932. Apparently, the decrease in marriages was related to business recession, the statisticians point out, since the sharpest decrease occurred in the period from September, 1957, through March, 1958. Data available thus far in 1959 indicate a small increase over the corresponding period of 1958. The annual number of marriages reportedly should climb after the early 1960's and remain at high levels for many years. There were wide geographic variations in the trend of marriages from 1957 to 1958, with 26 states showing decreases and 22 states and the District of Columbia having increases. The sharpest decreases were in those states with changes in their marriage laws, while adjoining states had the biggest increases. Indiana, where a waiting period has been required since January, 1958, had the biggest drop —45%. Marriages in the adjoining states of Ohio and Kentucky increased by 10% and 23%, respectively. In Mississippi, where the legal age for marriage was raised on July 1, 1958, marriages decreased by 42%. Among cities with at least one million population, Los Angeles alone showed no change. New York had a 3% decrease, Chicago and Philadelphia had 4% decreases, and Detroit almost 7%. Alaska and Hawaii, included in the United States record, had respectively a 3% increase and a 3% decrease in marriages.

CANADA

Symposium on Urethritis and Trichomoniasis.—The first Canadian Symposium on Non-Gonococcal Urethritis and Human Trichomoniasis will be held Sept. 21-22 at Notre Dame Hospital, Montreal, under the patronage of the Honorable Waldo J. Monteith, minister of national health and welfare, and Dr. Arthur J. B. Leclerc, minister of health of the Province of Quebec. Several European and American physicians will participate, including Dr. Pierre Durel, of Paris, chairman, International Study Group on Human Trichomoniasis; Dr. Gaston Chappaz, professor of gynecology, University of Reims; Dr. Ambrose J. King, director, Whitechapel Special Clinic; and Dr. Louis G. Feo, of the department of gynecology and obstetrics, Jefferson Medical College of Philadelphia. Interested physicians are invited. For information, write Dr. Zoltan Gallai, secretary of the symposium, 8580 Esplanade Ave., Montreal 11, Quebec, Canada.

FOREIGN

Meeting of French-Speaking Pediatricians.—The 17th Congress of the French-Speaking Society of Pediatrics will take place Oct. 12-14 at Montpellier, France, under the presidency of Prof. Jean Chaptal. Subjects include the following:

Hypoparathyroidism in Nurslings and Children.
Neonatal and Childhood Icterus.
Physiological and Pathological Aspects on Electroencephalography in the Course of Cerebral Maturation.

For information concerning the congress write Prof. Jean Chaptal, General Secretary of the Congress, 8, rue Guillaume-de-Nogaret, Montpellier, France.

Congress on Chest Diseases.—The sixth International Congress on Diseases of the Chest, sponsored by the American College of Chest Physicians, will be held at the University of Vienna from Aug. 28 to Sept. 1, 1960, organized by medical societies of Austria. The program includes problems connected with the physiology, pathology, clinical aspects, and therapy of the diseases of the organs of the chest in the adult and in the child. Scientists, clinicians, and practitioners from all parts of the world will attend. It is intended to have simultaneous interpretation of the papers in English, French, German, Russian, and Spanish. For information, write Prof. Dr. A. Sattler, Generalsekretar, American College of Chest Physicians, Wien IX, Frankgasse 8, Austria.

Meeting of Cardiovascular Society in Munich.—The fourth International Congress of the International Cardiovascular Society will be held Sept. 18-20 in Munich, Germany, at Das Deutche Museum, under the presidency of Dr. Michael E. DeBakey, Houston, Texas. A cardiovascular forum, Sept. 18, will be a joint session with the International Society of Surgery. A symposium on arterial grafts will be held Sept. 19, and a symposium on open heart surgery, Sept. 20. A program of motion pictures on cardiovascular problems is planned. Simultaneous translation in English, French, German, and Spanish will be available for all presentations. Technical exhibits will be on display. For information, write Dr. Henry Haimovici, 715 Park Ave., New York 21, Secretary-General.

CORRECTION

Foundation for Medical Care.—In the italicized introduction to a paper on this subject in the Council on Medical Service section in THE JOURNAL, June 20, 1959, page 969, it was stated that the Los Angeles County Medical Association is the most recent medical society to approve the formation of such a foundation. The executive director of the Los Angeles County Medical Association writes that this statement is erroneous to this degree:

> The Council of the Los Angeles County Medical Association, which is its sole policy body, has not taken any official action regarding the approval of a Foundation for Medical

Care. In January, the Council authorized a postcard opinion-poll of the membership of LACMA, to see whether there was any interest in the formation of a Foundation. Following this, the Council of LACMA instructed its Medical Services Committee to make preliminary studies and conduct some hearings and find out more about the Foundation, and to date there has been no final report on the Foundation, and the Council has not taken any official action.

EXAMINATIONS AND LICENSURE

NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: Various Centers: Part I only, Sept. 9-10. Examinations must be received at least six weeks in advance of a specific examination date. Examining centers established after close of registration. Exec. Sec., Dr. John P. Hubbard, 133 South 36th St., Philadelphia 4.

EDUCATIONAL COUNCIL FOR FOREIGN MEDICAL GRADUATES, INC.

Educational Council for Foreign Medical Graduates: Stations around the world, Sept. 22. Final date for filing applications was June 22. Succeeding examinations—March 16, 1960 and Sept. 21, 1960. Exec. Director, Dr. Dean F. Smiley, 1710 Orrington Ave., Evanston, Ill.

BOARDS OF MEDICAL EXAMINERS

Alabama: *Examination.* Montgomery, June 21-23, 1960. Sec., Dr. D. G. Gill, State Office Bldg., Montgomery.

Alaska:* On application in Anchorage or Fairbanks. Sec., Dr. W. M. Whitehead, 172 South Franklin St., Juneau.

Arizona:* *Examination.* Phoenix, Oct. 14-16. *Reciprocity.* Phoenix, Oct. 17. Ex. Sec., Mr. Robert Carpenter, 826 Security Bldg., Phoenix.

Arkansas:* *Examination and Reciprocity.* Little Rock, Nov. 5-6. Sec., Dr. Joe Verser, Harrisburg.

California: *Written.* Los Angeles, Aug. 17-20; Sacramento, October 19-22. *Oral.* Los Angeles, August 15; San Francisco, November 14. *Oral and Clinical.* Los Angeles, August 16; San Francisco, Nov. 15. Sec., Dr. Louis E. Jones, Room 536, 1020 N Street, Sacramento.

Connecticut:* *Homepathic. Examination.* Derby, Sept. 8. Sec., Dr. Donald A. Davis, 38 Elizabeth St., Derby.

District of Columbia:* *Examination.* Washington, Dec. 14-15. *Reciprocity.* Washington, Sept. 14. Deputy Director, Mr. Paul Foley, 1740 Massachusetts Ave., Washington 6.

Florida:* *Examination.* Miami Beach, Nov. 22-24. Sec., Dr. Homer L. Pearson, 901 N.W. 17th St., Miami 36.

Georgia: *Examination and Reciprocity.* Atlanta, Oct. 13. Sec., Mr. Cecil L. Clifton, 224 State Capitol, Atlanta 3.

Guam: *Subject to Call.* Act. Sec., Dr. F. L. Conklin, Agana.

Indiana: *Examination.* Indianapolis, June 1960. *Reciprocity.* Indianapolis, fourth Wednesday of each month. Ex. Sec., Miss Ruth V. Kirk, 538 K. of P. Bldg., Indianapolis.

Kansas:* *Examination and Reciprocity.* Kansas City, January 1960. Sec., Dr. F. J. Nash, New Brotherhood Bldg., Kansas City.

Louisiana: *Examination and Reciprocity.* New Orleans, Dec. 3-5. Sec., Dr. Edwin H. Lawson, 930 Hibernia Bank Bldg., New Orleans 12.

Maryland: *Examination.* Baltimore, Dec. 8-11, Sec., Dr. Frank K. Morris, 1211 Cathedral St., Baltimore 1.

Massachusetts: *Examination and Endorsement.* Boston, July 14-17. Sec., Dr. David W. Wallwork, Room 37, State House, Boston 33.

Montana: *Examination and Reciprocity.* Helena, Oct. 6. Sec., Dr. Thomas L. Hawkins, 555 Fuller Ave., Helena.

Nebraska:* *Examination.* Omaha, June 13-15, 1960. Dir., Bureau of Examining Boards, Room 1009, State Capitol Bldg., Lincoln 9.

Nevada:* *Examination and Reciprocity.* Reno, Sept. 8. Sec., Dr. G. H. Ross, 112 North Curry St., Carson City.

New Hampshire: *Examination and Reciprocity.* Concord, Sept. 9-12. Sec., Dr. Edward W. Colby, 107 State House, Concord.

New Jersey: *Examination.* Trenton, Oct. 20-23, *Reciprocity.* Monthly, Sec., Dr. Royal A. Schaaf, 28 West State St., Trenton.

New Mexico:* *Examination and Reciprocity:* Santa Fe, Nov. 16-17. Sec., Dr. C. Derbyshire, 227 East Palace Ave., Santa Fe.

New York: *Examination.* Albany, Buffalo, New York and Syracuse, Dec. 8-11. Sec., Dr. Stiles D. Ezell, 23 South Pearl St., Albany.

Ohio: *Examination.* Columbus, Dec. 15-17. *Endorsement.* Columbus, Aug. 26 and Oct. 5. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus 15.

Puerto Rico: *Examination.* San Juan, Sept. 8. Sec., Dr. Joaquin Mercado Cruz, Box 9156, Santurce.

South Dakota:* *Examination.* Sioux Falls, Aug. 25-26. Exec. Sec., Mr. John C. Foster, 300 First National Bank Bldg., Sioux Falls.

Tennessee:* *Examination.* Memphis, Sept. 23-24. Sec., Dr. H. W. Qualls, 1635 Exchange Bldg., Memphis 3.

Texas:* *Examination.* Fort Worth, Dec. 3-5. *Reciprocity.* Houston, Aug. 29-31. Sec., Dr. M. H. Crabb, 1714 Medical Arts Bldg., Fort Worth 2.

Wyoming: *Examination and Reciprocity.* Cheyenne, Oct. 5. Sec., Dr. James W. Shannon, State Office Bldg., Cheyenne.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Alaska: *Examination and Reciprocity.* Juneau, November. Sec., Dr. R. Harrison Leer, Alaska Office Bldg., Juneau.

Arizona: *Examination.* Tucson, Sept. 15. Sec., Mr. Herman E. Bateman, University of Arizona, Tucson.

Colorado: *Examination.* Denver, Sept. 2-3. *Reciprocity.* Denver, Sept. 4. Sec., Dr. Esther B. Starks, 1459 Ogden St., Denver 18.

Connecticut: *Examination.* New Haven, Oct. 10. Exec. Asst., Mrs. Regina G. Brown, 258 Bradley St., New Haven 10.

District of Columbia: *Examination.* Washington, Nov. 23-24. *Reciprocity.* Washington, Sept. 14. Deputy Director, Mr. Paul Foley, 1740 Massachusetts Ave., Washington 6.

Kansas: *Examination.* Pittsburg, Nov. 6-7. Sec., Dr. Leon C. Heckert, Kansas State College, Pittsburg.

Michigan: *Examination.* Ann Arbor and Detroit, Oct. 9-10. Sec., Mrs. Anne Baker, West Michigan Ave., 116 Stevens T. Mason Bldg., Lansing.

Minnesota: *Examination.* Minneapolis, Oct. 6-7. Sec., Dr. Raymond N. Bieter, 105 Millard Hall, University of Minnesota, Minneapolis.

Oklahoma: *Examination.* Oklahoma City, Sept. 25-26. Exec. Sec., Mrs. L. Haidek, 813 Braniff Bldg., Oklahoma City.

South Dakota: *Examination.* Vermillion, Dec. 4-5. Dr. Gregg M. Evans, 310 East 15th St., Yankton.

Texas: *Examination.* Austin, Oct. 12-13. Sec., Bro. Raphael Wilson, 407 Perry-Brooks Bldg., Austin.

Wisconsin: *Examination.* Madison, Sept. 11 and Milwaukee, Dec. 5, Sec., Mr. Wm. H. Barber, 621 Ranson St., Milwaukee.

---

*Basic Science Certificate required.

DEATHS

Amerson, Simeon Smith, Georgetown, Ky.; University of Nashville (Tenn.) Medical Department, 1897; served as president of the Scott County Medical Society; died in the John Graves Ford Memorial Hospital May 2, aged 90.

Antoni, Adolph I., Norwalk, Conn.; Boston University School of Medicine, 1927; associated with the Norwalk Hospital, where he died May 2, aged 57.

Arnett, John Hancock Jr., Philadelphia; University of Pennsylvania School of Medicine, Philadelphia, 1948; interned at the Cambridge City Hospital in Cambridge, Mass., and served a residency at the Harrisburg (Pa.) State Hospital; associated with the Mayview (Pa.) State Hospital; died May 7, aged 33.

Asa, Athenus Lewis, Morrill, Neb.; Lincoln Medical College of Cotner University, 1906; died in the West Nebraska General Hospital, Scottsbluff, March 8, aged 79.

Barnette, Ortha James, Shreveport, La.; Louisiana State University School of Medicine, New Orleans, 1952; interned at Charity Hospital of Louisiana in New Orleans, where he served a residency; served in the medical corps of the U. S. Naval Reserve; on the staffs of the T. E. Schumpert Memorial Sanitarium and the Physicians and Surgeons Hospital; died Feb. 7, aged 29.

Bennett, William Lewis Ⓜ Burnsville, N. C.; Lincoln Memorial University Medical Department, Knoxville, Tenn., 1911; member of the state legislature for two years; died in St. Joseph's Hospital, Asheville, April 30, aged 75.

Bingaman, Dixi McLean Ⓜ Salinas, Calif.; University of Southern California School of Medicine, Los Angeles, 1939; died April 28, aged 48.

Bowdoin, William Henry, Statham, Ga.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1913; died April 28, aged 79.

Braun, Eugene J. Ⓜ New York City; Universita Karlova Fakulta Lékarskà Praha, Czechoslovakia, 1932; specialist certified by the American Board of Psychiatry and Neurology; member of the American Psychiatric Association; interned at the Metropolitan Hospital in New York City, where he served a residency; served a residency at the Brooklyn State Hospital and the Central Islip (N. Y.) State Hospital; served on the staff of the Hillside Hospital; died May 7, aged 51.

Calonge, Guy Earl Ⓜ La Junta, Colo.; born in 1892; Loyola University School of Medicine, Chicago, 1918; served as secretary of the Otero County Medical Society of which he was president three times and one of the founders; formerly vice-president of the Colorado State Medical Society; member of the American Trudeau Society and the American Academy of General Practice; served three terms as a member of the District II School Board and as a member of the city council; his community efforts were recognized in 1954 when he received the third Civic Service Award of the Chamber of Commerce, of which he was a life member, and the naming of a building at Otero Junior College, Calonge Hall; veteran of World War I; associated with Mennonite Hospital and Santa Fe Hospital; died April 29, aged 66.

Castro, Cosimo Ⓜ Park Ridge, Ill.; Loyola University School of Medicine, Chicago, 1930; veteran of World War II; interned at Columbus Hospital in Chicago; associated with the Veterans Administration in Chicago, where he was adjudication officer at West Side Regional Office; in 1954, on 25th anniversary of graduation, he was cited for outstanding contributions as an alumnus by Stritch School of Medicine of Loyola University; died May 1, aged 60.

Chepko, Milan Daniel, Lyons, Ohio; Hahnemann Medical College and Hospital of Philadelphia, 1946; veteran of World War II; interned at the Easton (Pa.) Hospital and the Community General Hospital in Reading, Pa.; died in Flower Hospital, Toledo, April 29, aged 36.

Colburn, Charles Robert, Fairborn, Ohio; Eclectic Medical College, Cincinnati, 1927; died in the Community Hospital, San Bernardino, Calif., April 11, aged 64.

Collins, William Thomas, Albuquerque, N. M.; Northwestern University Medical School, Chicago, 1909; died in Fort Lyon, Colo., April 22, aged 75.

Davies, William Ⓜ Lyons, Ill.; Northwestern University Medical School, Chicago, 1924; member of the American Academy of General Practice; associated with the MacNeal Memorial Hospital in Berwyn, where he died April 19, aged 78.

Dean, Wesley N. Ⓜ Boyd, Texas; Baylor University College of Medicine, Dallas, 1901; for many years health officer; past-president of the Rusk County Medical Society; died in Overton (Texas) Hospital April 17, aged 90.

Ⓜ Indicates Member of the American Medical Association.

Dix, Sherwood, Largo, Fla.; Maryland Medical College, Baltimore, 1902; veteran of World War I; served on the staffs of various Veterans Administration hospitals; died in the Morton Plant Hospital, Clearwater, April 21, aged 85.

Donnell, Louis August, Wichita, Kan.; University of Louisville (Ky.) School of Medicine, 1937; served as city commissioner and mayor; veteran of World War II; on the staffs of Wesley and St. Joseph hospitals; died in Perryville, Ark., May 1, aged 53.

Doody, Richard Patrick Ⓜ Troy, N. Y.; Albany (N. Y.) Medical College, 1916; veteran of World War I; fellow of the American College of Surgeons; past-president of the Rensselaer County Medical Society; chief surgeon at St. Mary's Hospital; for many years surgeon for the police and fire departments; member of the executive board of his alma mater; past-president of the Lions Club; died May 8, aged 64.

Felsher, Wolf Zachary Ⓜ Chicago; Chicago College of Medicine and Surgery, 1917; veteran of World War I; for many years associated with the Michael Reese Hospital; civilian medical officer at the Fifth Army headquarters; died in the Grant Hospital May 9, aged 70.

Fischer, Edward James Ⓜ West Orange, N. J.; Georgetown University School of Medicine, Washington, D. C., 1922; police surgeon; associated with St. Mary's Hospital in Orange; died May 6, aged 61.

Ganley, Arthur Joseph Ⓜ East Orange, N. J.; Tufts College Medical School, Boston, 1916; veteran of World War I; associated with Presbyterian Hospital in Newark, where he died May 8, aged 70.

Hederick, Austin Ross Ⓜ Booneville, Ark.; Memphis (Tenn.) Hospital Medical College, 1902; veteran of World War I; honored in 1957 with a "Dr. Hederick Day" celebration at Booneville; for many years president of the school board; died in Newport April 25, aged 91.

Heinen, Joseph Peter, Chicago; Rush Medical College, Chicago, 1895; for many years diagnostician for the city board of health; served on the staffs of Alexian Brothers and St. Elizabeth hospitals; died May 10, aged 86.

Hindman, Thomas Audley Newcomer, Kensington, Md.; University of Pittsburgh School of Medicine, 1938; associated with Suburban Hospital in Bethesda; died April 28, aged 49.

Jameson, Winifred Mitchell Carney Ⓜ San Francisco; University of California School of Medicine, San Francisco, 1950; interned at Franklin Hospital; served a residency at the University of California Hospital and Franklin Hospital in San Francisco, and the Ernest V. Cowell Memorial Hospital in Berkeley, Calif.; resident in internal medicine at the Veterans Administration Hospital; died May 9, aged 46.

Jesion, Joseph William Ⓜ Pine River, Minn.; Milwaukee Medical College, 1912; veteran of World War I; for many years associated with the Northern Pacific Beneficial Association Hospital in St. Paul; died in the Veterans Administration Hospital in St. Cloud, April 29, aged 70.

Johannes, Richard L., Nevada, Mo.; Louisville (Ky.) Medical College, 1898; died in the Nevada Hospital April 25, aged 82.

Keller, Jacob Molier, Steeleville, Ill.; Washington University School of Medicine, St. Louis, 1904; died March 17, aged 79.

Kheiralla, George Ibrahim, Cambridge, Mass.; Northwestern University Medical School, Chicago, 1902; Chicago Homeopathic Medical College, 1900; author of "Arabia Reborn"; died April 18, aged 79.

King, Robert Rogers Ⓜ Wilkesboro, N. C.; University of Arkansas School of Medicine, Little Rock, 1906; health officer of Wilkes County; served as health officer of the district made up of Ashe, Alleghany, and Watauga counties; formerly health officer of Cherokie, Graham, and Clay counties; for many years a medical missionary for the Presbyterian Church in the Belgian Congo in Africa; died in Charlotte April 29, aged 74.

Kuhr, Ernestus Otto Ⓜ New York City; Columbia University College of Physicians and Surgeons, New York City, 1902; died in the Roosevelt Hospital May 7, aged 81.

Leventhal, Max Ⓜ Dolgeville, N.Y.; University of St. Andrews Conjoint Medical School, St. Andrews and Dundee, Scotland, 1933; at various times health officer of the towns of Manheim, Salisbury, and Dolgeville, in Herkimer County, and the town of Stratford in Fulton County; secretary of the staff of Little Falls (N. Y.) Hospital; died in the Mary Imogene Bassett Hospital, Cooperstown, April 11, aged 52.

Lichtwardt, Hartman A., Detroit, Mich.; Detroit College of Medicine and Surgery, 1917; also ordained a Presbyterian minister; a medical missionary in Iran for many years; served as medical director of the Woman's Hospital; fellow of the American College of Surgeons; died April 28, aged 66.

Lilienthal, Walter Scott, Albany, N. Y.; Albany (N. Y.) Medical College, 1910; on the courtesy staff of Albany Hospital, where he died April 28, aged 73.

McFarlane, Carl H., Honaker, Va.; Lincoln Memorial University Medical Department, Knoxville, Tenn., 1914; died in Rosedale, April 15, aged 73.

McGhee, Moses Alfred Ⓜ Daleville, Ala.; University of the South Medical Department, Sewanee, Tenn., 1898; past-president of the Dale County Medical Association; died April 20, aged 84.

McKeown, Charles Davis Ⓜ Wichita, Kan.; Loyola University School of Medicine, Chicago, 1918; specialist certified by the American Board of Anesthesiology; member of the Aero Medical Association and the Association of Life Insurance Medical Directors of America; past-president of the Sedgwick County Medical Society; medical director of the Farmers & Bankers Life Insurance Company; in 1949 appointed to the City Planning Commission; associated with St. Francis Hospital, Wesley Hospital, and St. Joseph Hospital, where he died April 29, aged 67.

McNally, Francis Joseph Ⓜ Pompano Beach, Fla.; born in Springfield, Mass., March 1, 1919; Columbia University College of Physicians and Surgeons, New York City, 1944; certified by the National Board of Medical Examiners; interned at the Bellevue Hospital, New York City; served a residency at the Traumatic Surgery Reconstructive Unit of the New York Post-Graduate Medical School and Hospital in New York City, City Hospital in Cleveland, and the Sunny Acres, Cuyahoga County Tuberculosis Hospital in Cleveland; for two years served in the medical corps, Army of the United States; associated with North Broward General Hospital and Holy Cross Hospital in Fort Lauderdale; died April 22, aged 40.

Macrae, Donald Hanley Ⓜ Topeka, Kan.; McGill University Faculty of Medicine, Montreal, Que., Canada, 1937; interned at the Montreal General Hospital in Montreal, Que., Canada, where he served a residency; served a fellowship at Menninger Sanatorium in Topeka and a residency at the Veterans Administration Hospital in Topeka; since 1950 county coroner; died in St. Francis Hospital April 26, aged 52.

Malbin, Barney Ivan, Portland, Ore.; Rush Medical College, Chicago, 1936; specialist certified by the American Board of Internal Medicine; served on the faculty of his alma mater; formerly associated with the Michael Reese Hospital in Chicago; veteran of World War II and received the Air Medal; on the staff of the Holladay Park Hospital; died May 4, aged 49.

Mayo, Dana Bartlett, Kennebunk, Maine; Boston University School of Medicine, 1906; past-president of the York County Medical Society; veteran of World Wars I and II; served in the U. S. Public Health Service, U. S. Judication Board, Washington, D. C., and the Veterans Administration; died April 19, aged 76.

Meboe, Joseph Ⓜ Viola, Wis.; University of Wisconsin Medical School, Madison, 1941; veteran of World War II; awarded the Purple Heart and the Bronze Star; served on the staffs of the Richland Center (Wis.) Hospital and the Vernon Memorial Hospital in Viroqua; died in La Crosse May 3, aged 48.

Mitchell, Roscoe L. Ⓜ Augusta, Maine; University of Vermont College of Medicine, Burlington, 1908; retired as director of the bureau of health in the state department of health and welfare May 1, 1947; city physician and city health officer; member of the American Public Health Association and the Maine Public Health Association; served as vice-president and executive member of the U. S. Association of State and Territorial Health Officers; physician for the Kennebec County Jail; on the staff of Augusta General Hospital, where he died April 21, aged 82.

Moore, Clyde Newton, Murrieta, Calif.; Lincoln (Neb.) Medical College, of Cotner University, 1911; served on the staff of the Community Hospital in Long Beach; died in Garden Grove, March 25, aged 77.

Munford, Raymond Hunter Ⓜ La Habra, Calif.; Kansas Medical College, Medical Department of Washburn College, Topeka, 1907; veteran of World War I; died April 15, aged 79.

Munsell, William Marvin, Grandview, Wash.; Missouri Medical College, St. Louis, 1895; veteran of World War I; served as medical examiner for the Northern Pacific and Union Pacific railroads; died April 19, aged 87.

Murray, Louis Floyd Ⓜ St. Louis; St. Louis College of Physicians and Surgeons, 1911; served overseas during World War I; on the staff of the Lutheran Hospital, where he died April 26, aged 72.

Munzner, Ralph Ⓜ Alton, N. Y.; Hessische Ludwigs-Universität Medizinische Fakultät, Giessen, Hesse, Germany, 1923; county coroner; served with the German Army in World War I; member of the American Academy of General Practice; associated with Lyons (N. Y.) Hospital and the Myers Community Hospital in Sodus; died April 25, aged 62.

Noonan, George Matthew Ⓜ Denver; University of Pittsburgh School of Medicine, 1906; also a pharmacist; died April 20, aged 79.

Orcutt, Dwight Chapman Ⓜ Evanston, Ill.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1901; specialist certified by the American Board of Ophthalmology and the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; for many years on the staff of St. Luke's Hospital in Chicago; died in Chicago May 13, aged 86.

Opperman, Ralph Clifford, Miami, Fla.; Jefferson Medical College of Philadelphia, 1923; died April 13, aged 58.

Padykula, Stanley George Ⓜ Endicott, N. Y.; Medical College of South Carolina, Charleston, 1939; veteran of World War II; formerly member of the Union-Endicott School Board; served on the staffs of Charles S. Wilson Memorial Hospital in Johnson City and the Ideal Hospital; died May 1, aged 47.

Paepke, Paul, Milwaukee; Eclectic Medical College, Cincinnati, 1926; died in the Milwaukee Hospital April 29, aged 62.

Pendleton, George Franklin Ⓜ Kansas City, Mo.; Western Reserve University School of Medicine, Cleveland, 1914; specialist certified by the American Board of Obstetrics and Gynecology; member of the Central Association of Obstetricians and Gynecologists; fellow of the American College of Surgeons; on the staffs of the General and Menorah hospitals; member and past-president of the staffs of St. Mary's Hospital and the Trinity Lutheran Hospital, where he was chairman of the obstetrics department and where he died May 5, aged 75.

Philipp Von Sielentz, W. M., Great Neck, N. Y.; Universität Leipzig Medizinische Fakultät, Saxony, Germany, 1927; during World War II served as a major, medical corps, 104th Field Artillery; died April 18, aged 62.

Pierce, William Meredith Ⓜ Tuscumbia, Ala.; Memphis (Tenn.) Hospital Medical College, 1903; past-president of the Colbert County Medical Society; served in France during World War I; died April 30, aged 75.

Plummer, Albert Wyman Ⓜ Lisbon Falls, Maine; Medical School of Maine, Portland, 1894; served three terms in the state legislature; on the staff of the Central Maine General Hospital in Lewiston, where he died May 1, aged 90.

Randall, John Hammond Ⓜ Iowa City, Iowa; State University of Iowa College of Medicine, Iowa City, 1928; certified by the National Board of Medical Examiners; specialist certified by the American Board of Obstetrics and Gynecology; member of the Central Association of Obstetricians and Gynecologists; fellow of the American College of Surgeons; past-president of the Iowa Obstetrics and Gynecology Society; professor and head of the department of the obstetrics and gynecology, State University of Iowa College of Medicine, where he was a member of the staff since 1934; associated with University Hospital, where he died April 19, aged 60.

Ray, Claud Burton, Cassadaga, Fla.; Michigan College of Medicine and Surgery, Detroit, 1906; formerly practiced in Detroit; died in Halifax District Hospital in Daytona Beach, April 28, aged 77.

Ray, Thomas Allen, Falls Church, Va.; Johns Hopkins University School of Medicine, Baltimore, 1952; interned at the Grace-New Haven Community Hospital, New Haven Unit, New Haven, Conn., where he served a residency; veteran of World War II; associated with Georgetown Hospital in Washington, D. C., and the Arlington (Va.) Hospital; died in Washington, D. C., May 6, aged 34.

Rech, Joseph Francis Ⓜ Indiana, Pa.; Georgetown University School of Medicine, Washington, D. C., 1931; veteran of World War II; served as secretary of the Indiana County Medical Society; on the staff of the Indiana Hospital; died April 18, aged 54.

Remington, Avon Charles Ⓜ Los Angeles; Harvard Medical School, Boston, 1940; interned at the Rochester General Hospital in Rochester, N. Y.; served a residency at the New York State Psychiatric Institute and Hospital in New York City and the Compton (Calif.) Sanitarium; veteran of World War II; member of the Aero Medical Association and the Industrial Medical Association; medical director, Garrett Corporation, Air Research Division; associated with the Daniel Freeman Memorial Hospital in Inglewood; died May 6, aged 43.

Robin, Percival Albert Ⓜ Hempstead, N. Y.; McGill University Faculty of Medicine, Montreal, Que., Canada, 1932; specialist certified by the American Board of Radiology; member of the American Roentgen Ray Society; fellow of the American College of Radiology; past-president of the Radiological Society of the State of New York; associated with Nassau Hospital in Mineola, Manhasset (N. Y.) Medical Center, and the Meadowbrook Hospital in Hempstead; veteran of World War II; died April 30, aged 52.

Rollins, Wiley Jackson Ⓜ Houston, Texas; University of Virginia Department of Medicine, Charlottesville, 1925; fellow of the International College of Surgeons; member of the Industrial Medical Association; for many years on the staff of the Memorial Hospital, where he died May 2, aged 58.

Rombkowski, John Anthony Ⓜ Toledo, Ohio; Loyola University School of Medicine, Chicago, 1918; member of the American Academy of General Practice; on the staff of St. Vincent's Hospital, where he died April 14, aged 74.

Rothschild, Charles Joseph Ⓜ Fort Wayne, Ind.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1905; past-president of the Fort Wayne Medical Society (Allen County); at one time served as Allen County coroner; served as chief of staff, St. Joseph's Hospital; died April 28, aged 77.

Rousuck, A. Ashley Ⓜ Cleveland; Wayne University College of Medicine, Detroit, 1940; interned at Robert Packer Hospital in Sayre, Pa., where he served a residency; entered Mayo Foundation in Rochester, Minn., as a fellow in internal medicine in October, 1942, and left in October, 1945; on the staffs of the St. Luke's and Mount Sinai hospitals; died April 22, aged 48.

Rudie, Clifford Norman Ⓜ St. Peter, Minn.; University of Louisville (Ky.) School of Medicine, 1928; died in the Methodist Hospital, Rochester, April 16, aged 59.

Ryall, Wallace Wilberforce Ⓜ Youngstown, Ohio; Western Pennsylvania Medical College, Pittsburgh, 1897; past-president of the Mahoning County Medical Society; veteran of World War I; served as city health commissioner, member of the city board of health and the state board of health; chief examiner for the Civil Service Commission, a judge for the Boxing Commission, president of the Kiwanis Club for a term and one of its directors for many years; on the emeritus staff, Youngstown Hospital Association; died in the Sawyer Sanatorium in Marion April 25, aged 84.

Ryan, William Butler Jr., Beaufort, S. C.; Medical College of South Carolina, Charleston, 1914; veteran of World War I; on the staff of the Beaufort Memorial Hospital; died May 8, aged 67.

Ryder, Charles Ambler, Brookfield Center, Conn.; Yale University School of Medicine, New Haven, 1898; served as postmaster and as secretary of the board of education for many years; died in the Fairfield State Hospital in Newtown April 23, aged 84.

Samuel, Meredith Ivor Ⓜ Wilmington, Del.; University of Maryland School of Medicine, Baltimore, 1900; served overseas during World War I; past-president of the Medical Society of Delaware; retired from the Veterans Administration Nov. 30, 1953; chief of medical service, Delaware, St. Francis, and Wilmington General hospitals; consultant, Delaware State Hospital, Farnhurst; served as medical director of the Brandywine Sanatorium in Marshalltown; died in the Veterans Administration Hospital, Elsmere, April 22, aged 83.

Sanford, Arthur Hawley Ⓜ Rochester, Minn.; born in New Albin, Iowa, Jan. 12, 1882; Northwestern University Medical School, Chicago, 1907; from 1907 to 1911 a member of the faculty of medicine at Marquette University, Milwaukee, where he was successively assistant professor, associate professor, and professor of physiology; emeritus member of the staff at the Mayo Clinic, where in 1911 he entered as bacteriologist, and was director of the clinical laboratories; head of the section of clinical pathology until 1946 at which time he became a senior consultant, and in 1949 retired from the clinic; emeritus professor of clinical pathology in the Mayo Foundation, Graduate School, University of Minnesota; when the foundation was established in 1915, he was appointed an associate professor of clinical pathology and parasitology; advanced to professor in 1921 and held this chair until 1950; elected first president of the American Board of Pathology, Inc., in 1936 and held this post until 1946; one of the original trustees of the board; chairman, Section on Pathology and Physiology, American Medical Association, 1929-1930; a charter member and past-president of the American Society of Clinical Pathologists, which in 1933 awarded him the Ward Burdick gold medal; in 1956 was honored at the annual meeting of the College of American Pathologists, of which he was a member, with the award of the Scientific Products Foundation, "in recognition of his outstanding service to pathology and to the field of medicine"; fellow of the American College of Physicians; member of the Minnesota State Medical Association, which elected him to the 50-year club in 1957, the American Association for the Advancement of Science, the American Society of Immunologists, the Society for Experimental Biology and Medicine, the Alumni Association of the Mayo Foundation, the Society of the Sigma Xi, Alpha Omega Alpha, Alpha Kappa Kappa, and Sigma Nu; Northwestern University conferred a distinguished service award on him in 1940; appointed an honorary consultant to the Army Medical Library in Washington, D. C.; in 1950 the board of regents of the University of Minnesota awarded him a certificate of merit for his long service to the university as a member of the faculty of the Mayo Foundation; in 1947 the Minnesota Society of Clinical Pathologists established the Arthur H. Sanford Lecture in Pathology in his honor; the lecture is given by an outstanding figure in the field at annual sessions of the Minnesota Medical Association; appointed a special consultant to the U. S. Public Health Service and a member of the advisory council on serology of that agency; member of the board of directors of the Rochester Public Library from 1914 to 1924; member of the Rochester Board of Education from 1924 to 1940 and served as president for 14 years of that time; president of the Olmsted County Historical Society from 1948 to 1950; first registered scoutmaster in Rochester and was a member of the national council of Boy Scouts of America; received a veterans' award for 40 years of service to the Boys Scouts in 1953; since 1950 director of the laboratories at the Rochester State Hospital; co-author of "Clinical Diagnosis by Laboratory Methods," the 12th edition of which appeared in 1953; died April 28, aged 77.

Sarubin, Benjamin Ⓜ Baltimore; George Washington University School of Medicine, Washington, D. C., 1927; died in the Lutheran Hospital April 23, aged 61.

Selleck, Nathaniel Benedict Ⓜ St. Petersburg, Fla.; Long Island College Hospital, Brooklyn, 1924; formerly practiced in Danbury, Conn., where he was associated with Danbury Hospital, and served as president of the Fairfield County Medical Society; died in St. Anthony's Hospital April 21, aged 60.

Shapleigh, Edward E. Ⓜ Kittery, Maine; Medical School of Maine, Portland, 1890; served as health officer and coroner for many years; died in the York Hospital, York Village, April 27, aged 91.

Shoaff, Paris Alexander Ⓜ New Castle, Pa.; Jefferson Medical College of Philadelphia, 1918; past-president of the Lawrence County Medical Society; fellow of the American College of Surgeons; associated with New Castle and Jameson Memorial hospitals; died April 22, aged 66.

Shull, Ernest Clay Ⓜ Herndon, Va.; Medical College of Virginia, Richmond, 1924; *served in France* during World War I; for many years member of the school board; past-president of the Rotary Club; associated with Loudoun Hospital in Leesburg, Arlington (Va.) Hospital, Washington Medical Center, Georgetown Hospital, and the Doctors Hospital, Washington, D. C., where he died May 7, aged 65.

Slaughter, Clarence Baden Powell Ⓜ Cleveland; University of Toronto Faculty of Medicine, Toronto, Ont., Canada, 1923; veteran of World War I; died in South Euclid, Ohio, April 24, aged 58.

Smith, Adonis Ⓜ Hope, Ark.; Memphis (Tenn.) Hospital Medical College, 1904; veteran of the Spanish-American War and World War I; died in Little Rock April 22, aged 88.

Smith, Ernest Franklin, Kenton, Del.; College of Physicians and Surgeons, Baltimore, 1905; formerly executive secretary of the state board of health; served as health commissioner of Sussex County and Kent County; died April 17, aged 82.

Smith, Grace F., Chicago; Chicago College of Medicine and Surgery, 1913; died in the Englewood Hospital April 1, aged 72.

Smith, J. Russell Ⓜ Middleburgh Heights, Ohio; Western Reserve University School of Medicine, Cleveland, 1951; interned at the City Hospital in Cleveland, where he served a residency; specialist certified by the American Board of Surgery; veteran of World War II; demonstrator of surgery at his alma mater; associated with Fairview Park Hospital in Cleveland; on the staff of the Community Hospital in Berea; died April 20, aged 34.

Sothoron, Levin Johnson Ⓜ Charlotte Hall, Md.; Georgetown University School of Medicine, Washington, D. C., 1896; for many years served as school physician of Charlotte Hall Military Academy; on the staff of St. Mary's Hospital in Leonardtown; died in La Plata April 19, aged 86.

Spikes, James Lewis, Pocahontas, Ark.; University of Arkansas School of Medicine, Little Rock, 1928; died April 19, aged 57.

Staff, Edmond Peter Ⓜ Ramsey, Ill.; Missouri Medical College, St. Louis, 1895; veteran of World War I; for many years a member of the school, serving as president for 22 years; died in the Fayette County Hospital, Vandalia, April 18, aged 89.

Taylor, John Eldredge, Morganton, N. C.; Medical College of Virginia, Richmond, 1922; died in the Grace Hospital April 16, aged 68.

Vorhaus, Martin Grossman Ⓜ New York City; University Bellevue Hospital Medical College, New York City, 1918; specialist certified by the American Board of Internal Medicine; member of the American Gastroenterological Association; veteran of World War I; consultant, internal medicine, Hospital for Joint Diseases; in 1935 received a special Certificate of Merit from the American Medical Association for group exhibit for studies on crystalline vitamin B_1; author of "A Guide to General Medical Practice," "The Changing Patient-Doctor Relationship," and "Adam's Rib"; died in the Lenox Hill Hospital April 29, aged 62.

Weinstein, Adolph Joseph Ⓜ Charlotte Amalie, Virgin Islands; Long Island College Hospital, Brooklyn, 1922; specialist certified by the American Board of Otolaryngology; served on the staff of the New York Polyclinic Medical School and Hospital in New York City; on the staff of Knud-Hansen Memorial Hospital and department of health; died April 15, aged 61.

Weiss, Jacob Joseph, New York City; University and Bellevue Hospital Medical College, New York City, 1915; died in the Bronx Hospital April 21, aged 68.

Wentworth, Ernest, Limington, Maine; College of Physicians and Surgeons, Boston, 1902; died April 15, aged 85.

Wight, Bennett Allen Ⓜ Kermit, Texas; Tulane University School of Medicine, New Orleans, 1926; veteran of World War II; county health officer; member of the Kermit Chamber of Commerce; on the staff of the Winkler County Memorial Hospital, where he died April 17, aged 57.

Wohlford, Reuben Franklin Ⓜ South Charleston, W. Va.; Medical College of Virginia, Richmond, 1942; interned at Lewis-Gale Hospital in Roanoke, where he served a residency; veteran of World War II; chief of staff and past-president of staff, Herbert J. Thomas Memorial Hospital, where he died April 19, aged 45.

DENMARK

Functional Myalgias.—L. H. Leinøe (*Nord. med.* 61:609-611 [April 16] 1959) drew attention to the fact that patients with functional myalgias often had symptoms indicating dysfunction of the autonomic nervous system, such as coldness of the extremities and acrocyanosis. These patients did not seem to tolerate the usual treatment by deep heat and massage, particularly short-wave diathermy. The reason for this might be a sympathetic dominance previously shown to occur frequently in these patients. Anxiety states, psychic stress, frustration, and maladjustment lead to autonomic imbalance and vascular instability associated with ischemia, oxidative changes, and muscular spasm induced by pain. A group of 27 patients with myalgia and objective signs of autonomic dysfunction were treated with indirect heat in the form of whole-body cold packs, under the influence of which there occurred a reflex vasoconstriction of short duration, followed by maximal dilatation and warming. These patients responded well to this form of treatment. There were no untoward reactions and all became free from pain or relieved of most of their symptoms. This effect was indicative of an autonomic dysfunction in the muscles.

INDIA

Thoracoplasty and Ventilatory Functions.—Gharpure and Nigam (*Indian Journal of Surgery,* vol. 21, February, 1959) stated that the effect of thoracoplasty in patients with pulmonary tuberculosis is not limited to the healing of cavities; it may also damage the adjoining lung tissue. The thoracic cage on the side operated on becomes relatively rigid and immobile, causing diminution of respiratory excursions and ventilatory function. This is further aggravated by the deformity of the spine resulting from thoracoplasty. The authors estimated pulmonary function before and three months after thoracoplasty in 12 patients. The vital capacity was found to be uniformly lowered after the operation. No patient with a vital capacity of below 2,000 cc. was accepted for operation. The average normal values for maximum breathing capacity (MBC) in men is 150 and in women 100 liters. An MBC below 40% of the predicted value is not sufficient for daily requirements.

In two patients in this study it was lowered to 42 and 45 liters after thoracoplasty, making them more or less respiratory cripples. Two others with an MBC of 55 liters became dyspneic on walking or slight exertion. Six had an MBC of almost 100 liters before operation and these retained good ventilatory capacity even after operation. The walking dyspneic index (walking ventilation x 100/MBC) is important for assessing the degree of pulmonary insufficiency. Normally it is below 0.3. The patient is a respiratory cripple when it goes above 0.5, as it did in two patients after thoracoplasty. Five patients had an index of 0.35 or less and showed no symptoms of pulmonary insufficiency. The remaining five with a walking dyspneic index between 0.35 and 0.5 had restricted working capacity after operation. Bronchospirometry was performed to determine the relative contribution of each lung to the respiratory effort. Bronchoscopy was performed one week before this investigation to exclude stenosis of the left bronchus and tracheobronchitis. It was found that the isolated function of each lung was quite different from that assessed by clinical examination.

In two patients the contribution of the relatively healthy lung was insufficient, markedly interfering with pulmonary function. The loss of pulmonary function was proportional to the extent of the operation. All these tests helped in planning the treatment for pulmonary tuberculosis, since the aim of these investigations was screening of the respiratory status rather than its complete evaluation. Patients with borderline lung function usually have a stormy convalescence. The loss of pulmonary function three months after six-rib thoracoplasty was 25 to 30% and after nine-rib thoracoplasty 40 to 45%. This observation helped in assessing the ventilatory loss that would probably follow operation and was a reason for refusing thoracoplasty in three patients. The probable advantages of thoracoplasty must be calculated on the amount of pulmonary function that would be retained after operation, and the operation should not be undertaken if it is likely to cause respiratory disability.

To improve pulmonary function patients to be subjected to thoracoplasty were taught to increase their breathing reserve by localized breathing exercises, especially diaphragmatic breathing, and breathing through the lower part of the chest while simultaneously relaxing the upper part. This also helped in preventing postoperative complications. Physiotherapy and exercises of the shoulder and

---

The items in these letters are contributed by regular correspondents in the various foreign countries.

back muscles were used to prevent scoliosis and deformity of the shoulder. These helped in preserving pulmonary function and working capacity.

Psoas Abscess.—Risko and Varga (*Indian Journal of Surgery*, vol. 21, February, 1959) stated that the findings on palpation in patients with psoas abscess are not always reliable. They tried to correlate radiologic changes with findings at operation in 30 such patients. Changes in psoas muscles such as enlargement of this muscle or disappearance in its contours occur in other conditions besides tuberculous spondylitis such as abscess of the muscle itself, hematoma, perforation of a paranephric or appendicular abscess, rarely primary tumors, and sometimes after major abdominal or renal operations. Roentgenologic examination reveals only the suprapelvic part of the psoas contour while the lower part if affected can be detected by palpation. In obese patients with intestinal flatulence the use of tomograms has given good results. Of the 30 patients studied retroperitoneal exploration was performed on both sides in 5 and on one side in 25, revealing 40 to 500 cc. of pus or calcified caseous debris. Palpatory findings were negative in 11, all of whom were found to have psoas abscess at operation, 7 unilaterally and 4 bilaterally. Many of them had calcified abscesses the size of a hen's egg or smaller in the region of L-1 to L-3. Six had radiologic evidence of psoas abscess before operation on both sides, and 18 had it on one side. The radiogram was negative in four and doubtful in two because of gas formation.

Since all these at operation were found to have psoas abscess, even the roentgenogram is not always a reliable criterion, although in most of the patients the presence of an abscess in the psoas muscle was assumed on the basis of muscle enlargement or disappearance of the muscle border. Six patients had calcified debris filling the abscess cavity. All but one were children aged 4 to 11; the exception was an adult aged 31 in whom symptoms had started at the age of 14 years. The presence of calcified debris as evidenced by the roentgenogram indicated an early onset of the disease process in childhood. These lesions are not quiescent, as is usually believed. In three of six patients with calcified debris tubercle bacilli could be demonstrated, and five patients were proved to have active tuberculosis by histological examination. Thus the mere presence of calcification does not assure an entirely quiescent lesion. Of the remaining 24 patients culture was positive in 19 and there was histological evidence of tuberculosis in 23. Postoperative roentgenograms were taken in 15 who had preoperative radiologic evidence of psoas abscess. The psoas shadow became normal in 11 and was unchanged in 4, the cause of the persistent change in contour being an organizing hematoma or cicatrix as no pus was obtained on aspiration.

Intervertebral Disk Protrusions.—Ramamurthi and Jaganathan (*Indian Journal of Surgery*, vol. 21, February, 1959) reported a series of 47 patients with sciatica who were operated on. Of these 36 had single lateral protrusions of intervertebral disks, 4 had multiple disk protrusions, and 7 had central disk protrusions. A hemilaminectomy or quadrilaminectomy was performed on patients who had lateral disk protrusions with the patient lying prone with the pelvis and chest well supported. The dura on exposure when palpated felt hard if there was a disk protrusion. The nerve root was displaced medially to expose the protrusion.

Of the patients with lateral disk protrusions 70% had them between the dura and nerve root. The site of rupture could be seen in the annulus fibrosus which was incised when the nucleus pulposus protruded and could be easily picked up. The results were good when the disk came out as a full sequestrum. If it required the punch and scoop to get the nucleus out, postoperative pain in the back often persisted. Postoperative results were good when the patients were carefully selected for operation. In those with compression of the cauda equina a complete laminectomy was preferred. Results for central disk protrusions were good and recovery was complete. Those who had lumbar disk protrusions with predominantly orthopedic signs and without objective neurological signs did well with rest in bed and traction on both legs. If symptoms persisted in spite of such treatment, operation was indicated and fusion of the spine after removal of the disk might be considered.

Anesthesia in Thoracoplasty.—Singh and Kamra (*Indian Journal of Tuberculosis*, vol. 6, March, 1959) reported a series of 400 patients who had thoracoplasties. In 47 of these spinal anesthesia was induced with a 1:1,500 solution of dibucaine, with the patient lying on the sound side. The disadvantages of this method of anesthesia were the profound drop in blood pressure and the fact that coughing is not effective and is accompanied by some paradoxical movement. Regional anesthesia, alone or in combination, was used for 348 patients; thiopental, nitrous oxide, oxygen, and ether for 3; and ether endotracheally for 2. Of the 348 patients only 29 required supplementary anesthesia, either with thiopental or ether, regional anesthesia alone being used for 319. The advantages of this anesthesia were that full cooperation of the patient was possible; respiratory movements were minimal; paradoxical respiration was minimal; the use of diathermy was possible; bleeding was less; and dissemination of the underlying tuberculosis was minimal. Respiration was not hampered by the semiprone position, the condition of the patient at the end of the operation was much more satisfactory, and postoperative nursing care was easier as the patient was fully conscious and cooperative.

All patients between 10 and 15 years of age were operated on under regional anesthesia alone. None of the patients had any other tuberculous lesion. They were usually operated on in the lateral or semiprone position. Procaine was the preferred drug for regional anesthesia, a 0.5% solution for wheal raising and infiltration and a 2% solution for nerve block. The usual time taken for administering anesthesia was 20 to 30 minutes, and the effect lasted for about 3½ hours. Ten patients were given thiopental in addition to regional anesthesia, and 19 were given ether. Blood transfusion was not required in most of the patients operated on under this anesthesia. Paradoxical respiration was not common. A tear in the pleura occurred in 37 patients, but this was well compensated for in those in whom the vital capacity was good. There were four deaths in the series, all due to paradoxical respiration. Postoperative retention of urine developed in some patients on whom spinal anesthesia was used. Paralytic ileus occurred in one patient after operation, spasm of the vessels of the arm in one, and wrist drop in two.

Cor Pulmonale and Tuberculosis.—S. C. Kapoor (*Indian Journal of Tuberculosis,* vol. 6, March, 1959) stated that cor pulmonale has been diagnosed more and more frequently in recent years as a complication of pulmonary tuberculosis. The diagnosis is based on the absence of any other heart disease, the presence of definite heart failure or at least two of the common clinical features, and/or unequivocal electrocardiographic evidence. Most of the cases reported here were discovered during the last 18 months. In the authors' series of 66 such patients the youngest was 6 and the oldest 66 years of age. The known duration of the pulmonary disease before the diagnosis of cor pulmonale varied between six months and 28 years. Twenty-one patients had no cardiac symptoms but 10 of these had suggestive clinical signs. The most constant physical sign of cor pulmonale was a loud pulmonary second sound which was present in 50 patients. Parasternal heaving, although not well developed in all, was present in 33.

Roentgenograms were not of much diagnostic help. The best diagnostic help was the ECG. Thus right ventricular hypertrophy of various grades was present in 39, negative T waves in two leads or more in 26, right bundle–branch block in 11, and extraordinarily high symmetrical T waves in 5. Of the 66 patients 18 died. Although cor pulmonale does occur as a complication of pulmonary tuberculosis, its diagnosis is not always easy. Accentuation of the pulmonic second sound was the principal finding and even this may be absent. In half of the cases the diagnosis could not have been made clinically and an ECG was required. The importance of diagnosing this condition lies in the fact that the cardiac involvement can be checked if detected early enough. Control of secondary lung infection is important in these patients and this alone may help in their treatment.

ISRAEL

Vital Statistics.—The infant death rate dropped to 30.9 per 1,000 in 1958 as compared to 33.6 in 1957. The general death rate was down to 5.62 per 1,000 from 6.18 in 1957. An increase in hospital capacity from 3.03 beds per 1,000 population last April to 3.1 is expected in 1959.

***In Vivo* Staining in Bone Tumors.**—S. Schorr and co-workers, at a meeting of the I. M. A. in Jerusalem, stated that alizarin red S given intravenously by drip infusion to patients having malignant bone tumors had a definite affinity for new bone formation in and around malignant foci. At autopsy the bones gave evidence that malignant foci stained with alizarin were well delimited and even minute foci were easily visible. Both predominantly destructive and predominantly productive malignant metastases had an affinity for alizarin red S. The microscopic appearance of the stained foci showed that even the so-called osteolytic type of bone metastases had active new bone formation. Iodinated alizarin compounds are being prepared to be used as possible x-ray contrast mediums.

Intervertebral Disk Syndrome.—D. Michaeli and co-workers (*Harefuah* 45:265, 1958) treated 24 patients who had intervertebral disk syndrome with ACTH and chlorpromazine in order to reduce the edema of the traumatized nucleus pulposus and the accompanying muscle spasm. Active exercise was encouraged in these patients. The optimum effect was achieved with intravenous infusions of 10 to 20 mg. of ACTH and 50 mg. of chlorpromazine in 500 ml. of normal saline solution over a period of eight hours. The number of infusions usually varied from 1 to 5, although some patients required more. Several patients received corticosteroids after the course of infusions. In most patients dramatic relief from pain occurred within a few days after starting treatment, often within 24 hours, and in most there was an objective improvement with disappearance of difficulty in straight-leg raising and reappearance of the ankle jerks. In nine patients, however, objective improvement was not remarkable, despite rapid subjective improvement. In three there was no improvement, and diskectomy was performed. These three patients had the most severe lesions from the clinical point of view. In addition to the usual findings sensory disturbances and loss of the ankle jerks were present. Only 2 of the 15 patients in whom the previous attack had lasted less than three months failed to improve. When the previous attacks had lasted longer, the treatment was less effective.

NORWAY

Anticoagulant Therapy.—As Professor Owren pointed out, the Quick method for the control of anticoagulant therapy is not accurate enough and his own method is technically difficult, requiring the services of a specially equipped laboratory (*Tidsskrift for den norske laegeforening*, April 1, 1959). He has devised a new method. The all-in-one reagent he uses is dehydrated and vacuum-sealed. It contains an active cephalin-lecithin preparation, a weak thromboplastin reagent, both in optimal concentrations, stabilized bovine plasma completely free of the four factors to be determined, and calcium in optimal concentration. The reagent keeps for at least a year and tests have shown unchanged activity after 30 days' storage at 47 C. In solution and ready for use the reagent's activity remains constant for at least 12 hours at room temperature and 72 hours at 6 C. The new method has been worked out for capillary blood, citrated venous blood, and citrated plasma. Only 0.1 ml. of blood is needed. The test is quickly made and the results are known in two or three minutes. The new method eliminates the faults of earlier methods and reduces the risks of hemorrhages to a minimum. Its simplicity means that a minimum of experience is required of physicians who wish to make use of it.

Open-Door Policy in Asylums.—On the women's side of the Gaustad state asylum for care of the insane near Oslo much has been done in recent years to dispense with the locked-door policy, in spite of the difficulties experienced in retrieving escapees. The shops in the neighborhood have learned to deal helpfully with them, and their brief outings teach them to adjust themselves better to their circumstances within the hospital. Due in part to advances in pharmacology, vocational therapy, and greater freedom in the asylum, the past seven or eight years have shown a marked increase in the hospital's annual turnover. According to P. Sundby and co-workers (*Tidsskrift for den norske laegeforening*, April 1, 1959) the number of new admissions rose from 107 in 1950 to 189 in 1957, and the number of discharges from 96 to 173 in the same period. The number of readmissions remained at 45 to 50%. Since the asylum's capacity has been increased by the increase in turnover the waiting list has been so shortened that it is now rare for a new admission to be much delayed.

How a General Practitioner Spends His Time.—Working as a general practitioner in a farming and mining community Dr. O. H. Iversen (*Tidsskrift for den norske laegeforening*, April 15, 1959) kept a minute record for 18 months of all he did. The treatment of respiratory diseases accounted for 15% of his practice. Mental and emotional diseases accounted for only 3%. Among the laboratory tests performed hemoglobin determinations came first with 688, sedimentation rate determinations came second with 390, and microscopic examinations of urinary sediment came third with 94. Among the operations performed dental extractions numbered 653, incisions 80, punctures 14, and sutures of wounds 19. In 56 patients the tympanum was punctured, and in 28 warts or small tumors were removed. In 30 patients varicose veins were treated by injection. Each consultation took an average of 23 and each house call 54 minutes. The relatively high income of many physicians in private medical practice is only possible because of the long hours they put in.

Training Medical Students Abroad.—After World War II many prospective medical students had to go abroad because there was no room for them in Norwegian medical schools. By the end of 1958 the number of these medical expatriates was 690. Commenting on their fate in *Tidsskrift for den norske laegeforening*, April 15, Prof. A. Ström pointed out that they outnumbered the home-trained medical students, since the present entry of students to Norway's two medical schools is only 130 yearly. Before 1958 it was only 100 yearly. At present there are hospital vacancies enough for both home-trained and foreign-trained students, but the author foresaw a not distant day when the physician returning to Norway will find the medical profession painfully overcrowded. While he would not discourage the prospective physician with a natural bent for the art of healing he suggested that when earning a living is the main objective, the medical student contemplating a costly course of studies abroad would do well to think twice.

SWEDEN

Medullary Sponge Kidney.—Medullary sponge kidney is a condition in which all or part of the medulla of the kidney presents a sponge-like appearance, owing to the presence of multiple cysts and cavities formed by dilatation of the collecting tubules. N. Lindvall (*Acta radiol.* 51:193-206 [March] 1959) reported on a series of 35 patients with this condition. According to the roentgenograms the changes were bilateral in 23 and unilateral in 12. The ages of the patients ranged from 16 to 62 years. The progress of some patients was followed for as long as 16 years. In all the diagnoses were made from the urograms. The changes were of all grades, from a few cavities in a single pyramid of one kidney to multiple cavities in all the pyramids bilaterally. Enlargement of the involved pyramids was observed in 31 kidneys. Even in parts of the kidney where no cavities were visible some kidneys showed enlarged papillae and general hypertrophy, suggestive of the presence of changes which had not been directly shown, and the calices of the enlarged papillae were also enlarged.

In all but two patients from one to several hundred calculi were present, most of them round and dense and sometimes disposed in groups, thus presenting so distinctive a picture that the diagnosis was suggested even in conventional roentgenograms. If at the same time there was enlargement of the kidney, the diagnosis could in some cases be made without recourse to urography. During the observation period the only roentgenologic changes were signs of pyelonephritis, the formation or disappearance of stones (after passing), or the appearance of hydronephrosis due to the passage of a calculus. Malformations within the urinary tract, such as caliceal cysts and hypoplasia, were found in only four patients.

The conditions and changes that might be roentgenologically confused with medullary sponge kidney are renal tuberculosis, papillary necrosis, caliceal diverticula and cysts, tubular stasis, and various forms of nephrocalcinosis. As the clinical findings of medullary sponge kidney are determined solely by the complications, the diagnosis rests with the roentgenologist; it is facilitated by the fact that the changes do not appreciably affect the excretion of contrast medium. Medullary sponge kidney is so common that it deserves more attention than it has received.

Mortality and Muscle Relaxants.—The use of muscle relaxants is steadily increasing. T. Gordh (*Acta anaesth. scandinav.* 3:35-40, 1959) studied the use of such drugs in patients undergoing urologic, abdominal, and cancer operations. After intravenous injection of the drug the patients breathed 100% oxygen. Intubation if indicated was performed under the relaxation obtained with succinylcholine chloride, the dose usually not exceeding 50 mg. The required depth of anesthesia and relaxation were maintained by injections of a 5% narcobarbital solution and succinylcholine, administered at appropriate intervals. The gases inhaled consisted of a mixture of oxygen, 1 liter per minute, and a maximum of 3 liters of nitrous oxide per minute in a semiclosed system. In intra-abdominal surgery local infiltration of 0.5% lidocaine with epinephrine was occasionally used along the line of incision. In the years 1946 to 1957, in a total number each year of 4,000 to 5,000 patients, the postoperative mortality varied yearly from 1.1 to 1.6% while muscle relaxants were used with a frequency increasing from 1.0% in 1947 to 36.7% in 1957. The increase in the use of muscle relaxants occurred at the expense of the use of ether and spinal and local anesthetics. From 1944 to 1945 no muscle relaxants were used for operations on the biliary system. Succinylcholine was introduced in 1950. While the use of muscle relaxants in biliary operations has increased from 0 to 95.3%, the mortality has not changed.

Circulatory Disturbances in Osteoarthritis.—A. Hulth (*Acta orthop. scandinav.* 28:81-89, 1958) reported that intraosseous venographies of femoral heads were performed on 15 patients with osteoarthritis. Normally venograms showed circumflex veins. In patients with osteoarthritis of the hip venograms were characterized by accumulation of dye in the femoral head, evacuation of the contrast medium from the head occurring mainly via medullary veins coursing distally into the femoral shaft. The injection in patients with osteoarthritis was painful, but in persons with normal or slightly affected hips it was almost painless. In patients with osteoarthritis the venous pathways from the site of injection were entirely changed. The contrast medium in the diseased hips had to traverse a much longer intraosseous course before entering the large extraosseous veins, i. e., the femoroiliac veins. The pathological cancellous tissue in an arthritic femoral head created conditions for intraosseous venography that were entirely different from those encountered in normal bone. The contrast medium in the former might take a "false" course. It looked, however, on the roentgenogram as if the injected contrast medium had spread out in the entire femoral head and could therefore run out via epiphysial and metaphysial veins, if such veins existed. It was thus possible that these so-called retinacular veins had ceased to function in the severely osteoarthritic hip. The venogram might indicate a real venous stasis.

Diskography.—S. Nordlander and co-workers (*Acta orthop. scandinav.* 28:90-102, 1958) made a roentgenologic analysis of 73 patients with low back pain, sciatica, or both. Operation had been performed on all and most had undergone both myelography and diskography. The authors were unable to show that diskography was superior to myelography for routine diagnosis of herniation of an intervertebral disk, but it was difficult in part of this series to make a diskographic analysis. The authors concluded that there was good reason to stick to the use of myelography with injection of water-soluble contrast medium in routine examination for disk herniation producing nerve-root compression in patients with low back pain and sciatica, but that diskography could be used as a complementary method of examination.

Epiphysiolysis Capitis Femoris.—N. Lindström (*Acta orthop. scandinav.* 28:131-146, 1958) reported that between 1944 and 1955 54 hips in 51 patients were treated at the orthopedic clinic in Härnösand for epiphysiolysis of the femoral head; 26 hips were fixed in situ, 4 were treated by closed reduction, and subcapital wedge osteotomy was performed on 24. In one of the latter no internal fixation was performed, but all the others were fixed with a three-flanged nail except one which was fixed in situ by a wing screw. The follow-up period was about 4½ years. There was no necrosis of the femoral head in those hips nailed in situ. One patient treated by closed reduction had such a necrosis. Of those who underwent subcapital wedge osteotomy one had total and one partial necrosis of the femoral head, and one had traumatic arthritis with destruction of the joint cartilage. There were no poor results from fixation with a three-flanged nail, so this method of fixation was recommended by the author. Because the danger of necrosis occurring in patients with extensive slipping is great, the reduction must be handled with extreme care. The results of the subcapital wedge osteotomies with simultaneous nailing were satisfactory.

Depressions in Patients Treated with Reserpine.—K. Jensen (*Acta psychiat. et neurol. scandinav.* 34:195-204, 1959) reported on 11 women, all hospitalized because of depressions appearing after 1 to 10 months' treatment with reserpine for hypertension in daily doses of 0.50 to 0.75 mg. One patient had been given a whole-root preparation of Rauwolfia serpentina, containing 0.3 mg. of reserpine. The patients were aged from 42 to 76 years. A predisposition to depression was present in five. The symptoms were a deep sensation of unhappiness, frequent crying, restlessness, and anxiety. One patient attempted suicide. Seven patients were given electroconvulsive treatment, two a combination of electroconvulsive treatment and chlorpromazine, and two had chlorpromazine only. The treatment gave good results in all. About six months after leaving hospital two patients were again given reserpine and had to be readmitted to the hospital because of depression. Since the discontinuation of treatment with reserpine did not always bring about cessation of the symptoms, it was not supposed that reserpine was the only cause of symptoms but rather that it was a precipitating factor.

Multiple Injuries.—I. Palmer (*Opuscula med.* 4:83-90 [March] 1959) studied a series of 65 patients with multiple injuries. These patients had an average of 33 injuries each. Manifest shock was present in 41. The treatment should be directed against the following conditions in the following order of priority: (1) shock, continuous bleeding, respiratory obstacles, and epidural hematoma; (2) intestinal and gastric injuries; (3) large wounds; (4) fractures; and (5) head injuries. On account of the multiplicity of the injuries treatment of fractures must be divided into a primary and a secondary definitive phase. The healing of each injury seemed not to be delayed by the presence of other injuries.

Prognosis of Cardiac Infarction.—Helander and Levander (*Acta med. scandinav.* 163:289-304, 1959) studied some of the factors in the composition of the material which could influence the primary mortality and the long-term prognosis of patients with cardiac infarction. A series of 286 patients were divided with regard to the age, sex, and severity of the first attack of the myocardial infarction. The primary mortality was 32%. The difference in the primary mortality in relation to the age and sex of the patients was most clearly marked between the older and the younger women, being 48 and 6% respectively. While it was postulated previously that women had a higher mortality than men, this seemed to apply to the older women only. The difference between the older and the younger groups was less marked among men. Differences in the composition of various materials regarding the age and sex of the patients could therefore decisively influence the result.

In estimating the 5-year survival rate the authors analyzed the 232 patients who survived their first attack of cardiac infarction. After five years 58% were still alive. The severity of the infarction did not influence the continued course as markedly as the primary mortality. The difference which became apparent in the primary mortality between the younger and the older women was not matched by a similar difference in five-year survival rate, 62 and 49% respectively. A comparison between the five-year survival rate after the first attack of myocardial infarction in this series, on the one hand, and in a Stockholm population of the same age, on the other hand, showed a greatly increased mortality among the former. Autopsy showed that in 42 of the 80 patients examined there was thrombosis in the coronary artery. There was a coronary embolism in one.

There proved to be a good correlation between the electrocardiographic and the autopsy findings, as regards the localization of the infarction. Among the electrocardiographic changes the atrioventricular and the intraventricular heart block seemed to signify an essentially aggravated prognosis, with a 69% primary mortality as against 23% in patients whose ECG showed no such changes. A complete regression of electrocardiographic changes was noted in 23 paients. Of the 135 who survived for five years 85 were still alive at the follow-up examination time, i. e., on the average eight and one-half years after the myocardial infarction. Of the latter 78 were given a control examination; 21 were normally active and 23 were completely disabled. Twenty-four were free of angina pectoris. Of the abovementioned 78 patients 23 had had at least one relapse.

Primary Hyperparathyroidism.—J. Hellström (*Nord. med.* 61:551-556 [April 9] 1959) studied a series of 115 patients with hyperparathyroidism observed during the period 1930-1957. In more than 80% the diagnosis was made after 1950. Radiologically observable changes in the kidneys in the form of calculi or nephrocalcinosis were noted in 85%. In 52 patients 103 operations for renal calculi were performed. One patient underwent six operations. The author believed 3 to 5% of all cases of renal calculi were due to hyperparathyroidism. In all patients with hyperparathyroidism, even those in whom no radiologic changes in the kidneys were seen, a renal lesion was present. In the earlier stages this was functional and transient after successful parathyroidectomy; in the later stages it became structural, persistent, or progressive although the hyperparathyroidism was cured by operation.

As a manifestation of this renal lesion there was always impairment of the concentrating power of the kidney. Normal concentrating power almost surely excluded hyperparathyroidism. Among these patients 70% had hypertension and in several this led to incapacity or death from cerebral complications. The main cause of the hypertension was probably the renal damage. As regarded the skeletal changes osteitis fibrosa occurred less often in recent than in former times. In 8 patients the first symptom was a giant-cell tumor in the upper or lower jaw. The skeletal changes always healed, functionally if not anatomically. Peptic ulcer occurred in 33% of the males and 5% of the females. The diagnosis of hyperparathyroidism rested on clinical symptoms, radiologic examination, and laboratory procedures. Even a slight rise in the blood calcium level (10.5 to 11.0 mg. per 100 ml.) should arouse suspicion of hyperparathyroidism.

The prognosis of untreated hyperparathyroidism was generally poor. The prognosis after parathyroidectomy depended mainly on the degree of renal damage at the time of operation. In 22% of the author's series the operation was unsuccessful or incomplete. The reasons for this were removal of an insufficient number of glands in multiple adenoma or primary hyperplasia; confusion with lymph nodes or adenoma of the thyroid; very small adenomas; and abnormal location, the adenomas being enclosed in the thymus or the thyroid, or displaced to the mediastinum. In view of these difficulties and of the many yet unanswered questions concerning the pathogenesis of hyperparathyroidism, patients with this disease should be referred to hospitals that have the best facilities for its treatment.

New Operation for Gastric Ulcer.—Instead of reducing the volume of the stomach by half or more in the course of a partial gastrectomy, an operation that causes lasting inconvenience to about 50% of all patients so treated, Dr. S. Hedenstedt of Luleå uses 4 to 6 in. of small intestinal tissue to replace the resected stomach and retain the stomach volume. The follow-up period in about 33 of his series of about 100 patients treated by this method was two years, and in these patients the operations proved very successful. Another advantage of the method was that it offset the postoperative effect of reduced formation of blood corpuscles, formerly a frequent result of gastric operations. The 3 or 4% of patients who suffered from disabling complications after the first operation have had a second operation with surprisingly good results.

Professor Crafoord Honored.—Prof. Clarence Crafoord of Stockholm, the well-known thoracic surgeon, was named Doctor Honoris Causa at the University of Córdoba in Argentina. Last year Professor Crafoord and his co-workers performed a series of operations in Argentina and demonstrated their heart-lung machine.

Implantation Metastases in Renal Pelvis.—A. E. Nilson (*Acta chir. scandinav.* 116:306-314, 1958/1959) reported on five patients who had recurrent tumors of the bladder with secondary tumors of the renal pelvis. In three a urethral catheter was introduced and retrograde pyelography performed on the involved side to verify the diagnosis of pelvic tumor. Excretion in the affected kidney had ceased in one of these patients and was lowered in the others. In no instance had ureteral catheterization preceded the discovery of the renal pelvic tumor. Vesicoureteral reflux was detected prior to or at the same time as the renal pelvic tumor, three to eight years after the treatment of the initial bladder tumor. In no case in which the orifices were judged to be normal on cystoscopic inspection could vesicoureteral reflux be demonstrated. Cystoscopy revealed appreciable anatomic changes in all the ureteral orifices in which cystography disclosed reflux. There was strong evidence that implantation metastases from the bladder to the upper urinary tract might occur in the presence of defective valvular function with accompanying vesicoureteral reflux, permitting the retrograde transport of tumor cells. When vesicoureteral reflux is demonstrated, frequent urographic examinations of the upper urinary tract should be performed to facilitate early detection of implantation metastases.

Coccygodynia and Rhizotomy.—Bohm and Franksson (*Acta chir. scandinav.* 116:264-267, 1958/1959) reported on 15 patients with coccygodynia, 7 of whom had previously undergone rectal surgery and were treated by division of the lower sacral nerve roots. The operation relieved the pain completely in seven of the eight patients with "idiopathic" coccygodynia and in all seven who had rectal operations. In the patients who had undergone rectal surgery, a neurotraumatic cause of the coccygodynia was an important possibility, according to the authors. One patient was still alive and apparently without metastases. The others died fairly soon after rhizotomy. It is therefore possible that carcinomatous recurrences caused the pain in the coccygeal region. Rhizotomy in these patients must therefore be regarded as a purely denervating operation and as an alternative to chordotomy. The writers commented that the latter operation was a major undertaking and, if done bilaterally, might entail significant disability. A limited root section, the procedure in the present series, involves negligible neurological loss. The drawback of rhizotomy is that spread of the cancer gives rise to pain from other structures. The effect of rhizotomy may thus be transient. The most suitable patients for rhizotomy would seem to be those in whom the pain has long been concentrated in the coccygeal region.

UNITED KINGDOM

College of Surgeons Criticized.—A few weeks ago a Sunday newspaper carried photographs showing the president and council of the Royal College of Surgeons of England listening to the Hunterian oration. The names of the surgeons in the front two rows were given in full under the photograph so that they could easily be identified. In other papers gossip-column writers described a party held in the rooms of the college where stars of a television serial called "Emergency Ward 10" drank cocktails with some of the leading surgeons. All this was part of a publicity drive to get money for new buildings for the college.

This method of obtaining publicity was severely criticized in an editorial by the *British Medical Journal*, which said that if the college wanted money it should obtain it without loss of dignity and without giving publicity to the members of its council. Exception was also taken to full-page advertisements in the *New Statesman* and *Spectator*, announcing a television program called "Surgeon," in which the names of the president and six members of the college council were mentioned, complete with qualifications, distinctions, and honors. Criticism was also made of a picture in a Sunday newspaper of the president of the college rehearsing for a television show. The *British Medical Journal* thinks that bad advice was given to the college by its publicity experts. It would be a pity if the college, in achieving its goal of raising $8,500,000, found that it had lost something more precious than money in the process.

Malignant Melanoma.—Encouraged by successful experience with autogenous marrow replacement after large-field irradiation Westbury and co-workers treated a patient who had disseminated malignant melanoma with a massive intravenous dose of mannomustine hydrochloride, a cytotoxic drug, followed by reinfusion of the patient's own stored marrow (*Lancet* 1:968, 1959). The patient, a woman aged 38, was referred for treatment after the excision of a malignant melanoma over the right scapula. The primary site was irradiated, and after preoperative irradiation an axillary block dissection was performed. Within two months nodules appeared in the scalp, axilla, thorax, and thighs, and, in addition to gross enlargement of the liver, the brain also appeared to be involved. Radiography showed scattered metastases in the lungs. Bone marrow containing 800 million cells was aspirated under anesthesia from the sternum, iliac crests, and vertebral spines and stored at −79 C. Then 3,000 mg. of mannomustine was given intravenously over five days by rapid injection in a continuous 5% dextrose solution drip. In addition the patient received prednisone, perphenazine, tetracycline, and vitamin K. After the course of mannomustine was completed the stored marrow was thawed, reconstituted, and injected intravenously.

Regression of skin nodules began almost immediately, followed by a fall in the lymphocyte concentration and depression of the total leukocyte count. Within a few days headache, vertigo, and vomiting set in. The patient lapsed into unconsciousness and died one week after the marrow reinfusion. Death was due to hemorrhage into a necrotic metastasis in the left cerebellar hemisphere. At autopsy many of the nodules were seen to have regressed and undergone extensive central necrosis.

This case demonstrated that a large dose of a cytotoxic drug may be given with remarkably few side-effects, and yet produce a rapid and dramatic shrinkage of melanomatous deposits. Death from cerebral hemorrhage occurred too soon for the results of marrow transfusion to be seen in the circulating blood, but postmortem examination of the marrow suggested that regeneration was taking place. The rapid and unexpected regression of the deposits was sufficien[illegible] to warrant further trial of this [illegible] advanced cases.

Incidence of Gonorrhea Increasing.—According to a circular sent from the Ministry of Health to local health officers gonorrhea is increasing, particularly among women. In 1951 14,975 new cases in men and 3,089 in women were seen in the venereal disease clinics in England and Wales. In 1957 corresponding figures were 19,695 and 4,737. This represents an increase of 31% for men and 53% for women. This is a real increase and not merely a higher proportion of patients being treated. The increase continued in 1958. The Ministry of Health stated that a relatively small group of promiscuous infected women constitutes the most important factor in the spread of the disease, and it is this steadily increasing group that is the principal cause for concern. Although the number of women known to be infected is much smaller than the number of men, the proportion of the former who remain untreated is probably higher because infection is not so obvious in women. The Ministery of Health has asked local health officers to review arrangements for tracing contacts. This increase in the incidence of gonorrhea may be due to an increase in the number of strains of penicillin-resistant gonococci, to the belief that penicillin has made gonorrhea an easily cured infection, and to the ignorance of the public about the nature of the disease.

Clearance Rate of Insulin.—The rate of clearance of insulin labeled with radioactive iodine from subcutaneous sites in normal subjects and diabetics was studied by Joiner (*Lancet* 1:904, 1959). The labeled insulin was injected subcutaneously into various sites in the arm, leg, and abdomen in 97 control subjects of both sexes, mainly doctors and nurses, and serial counts taken at 30-second intervals over the injection site with a Geiger counter. All observations were made at a constant room temperature of 32 C and a standard injection of 8 units of insulin in 0.2 ml. of physiological saline solution, which corresponds to 1 mc. of radioactivity, was given. As an added protection for the thyroid gland 10 mg. of potassium iodide was given orally to most subjects before the experiment. In men the half-life of the isotope was 67 ± 11 minutes from the arm, 123 ± 18 minutes from the leg, and 76 ± 20 minutes from the abdomen. The corresponding figures for women were 55 ± 7, 99 ± 12, and 76 ± 20 minutes respectively. Variation in volume and concentration of the insulin and in the amount of exercise taken had no significant effect on the rate of clearance. The differences between the clearance rate in the arm and leg and between men and women were statistically significant. The rate of absorption of the insulin was significantly increased by the addition of hyaluronidase.

The radioactive insulin was also given subcutaneously to 41 diabetic patients. The clearance was slower in women than men, and in diabetics whose disease was of long standing than in those whose disease was of recent origin. As in normal subjects exercise had no effect on the rate of insulin clearance, which seemed to increase with age. Delayed absorption was not a significant factor in poorly controlled diabetics. A preliminary study indicated a possible association between lipodystrophy and delayed clearance.

Increase in Incidence of Leprosy.—The Minister of Health stated in Parliament that there are 275 patients with leprosy in the United Kingdom. One member asked why the number of cases has increased from 46 in 1951 to the present figure. He thought that the situation was becoming serious, since the disease is contracted outside the country and brought in by immigrants. In his opinion there should be some regulations to prevent the uncontrolled entry of immigrants suffering from the disease. The minister said that there is no evidence that leprosy is spreading. There are two special units in the country where inpatient treatment can be given. Sufferers from the disease can also be treated as outpatients in the infectious and tropical disease hospitals.

Breast Abscesses and Antibiotics.—According to Knight and Nolan breast abscesses in the puerperium are becoming resistant to treatment with antibiotics (*Brit. M. J.* 1:1224, 1959). They noted that the duration of infection and morbidity in 100 women with puerperal breast abscesses who required hospitalization was greater than in a comparable group studied in the same hospital 16 years ago, before the use of antibiotics. The increase was attributed partly to the widespread use of these. At the moment there is a high degree of antibiotic resistance in the strains of Staphylococcus aureus isolated from puerperal breast abscesses; 93% were found to be resistant to penicillin, 55% to streptomycin, 40% to oxytetracycline, but only 1% to chloramphenicol, which is regarded as the preferred antibiotic. When the organism is antibiotic-resistant the pathological features are modified unfavorably. Tissue necrosis and pus formation are retarded, while repair proceeds uninhibited, but a thick fibrous wall forms around the abscess, delaying resolution and preventing collapse of the cavity after incision. A further result of this increased fibrosis is the tendency to produce unsightly shrunken breasts.

The incidence of mastitis and breast abscess in women delivered in hospital was found to be more than double that in women who had home confinements. This was associated with the heavy colonization of the baby's nasopharynx with organisms from the hospital environment in which it spends the first few days of life. These organisms were the same as those recovered from the breast abscesses, but were different from those carried in the mother's nares. Another important etiological factor in these breast infections was milk engorgement, which often resulted from stopping breast feeding without taking adequate measures to suppress lactation and empty the breasts. At least 33% of those with breast abscesses had stopped breast feeding as soon as they left hospital. The authors suggested that the incidence of puerperal breast abscess could be reduced by allowing mothers who wish to bottle-feed their babies to do so straight away. Lactation can be suppressed with diethylstilbestrol in these patients and in those in whom breast feeding is stopped for any reason. Antibiotics should be given if infection is suspected, but if there is no local response to these after two days their administration should be stopped. The antibiotic least likely to cause resistance is chloramphenicol.

Mass Radiography and Cancer of Lung.—It is generally accepted that mass radiography of the chest offers the best known single means of detecting, as rapidly and as economically as possible, significant intrathoracic lesions in the general population. National morbidity figures suggest that at present mass radiography does not find more than 10% of all new cases of cancer of the lung in England and Wales, but it can be an effective method for locating early cases before symptoms appear. Posner and co-workers attempted to assess the value of conventional routine mass radiography in detecting early asymptomatic cases of carcinoma of the lung by comparing cases found by this means with those discovered among patients referred by general practitioners because of suspicious symptoms (*Brit. M. J.* 1:1213, 1959). A comparison of the resectability of the lesions in the two groups of patients was made. A slightly higher rate of resectability was found in those discovered in routine mass radiography surveys, although this was not statistically significant. The two-year survival rates, irrespective of treatment, were higher in the mass radiography group (25%) than in the general practitioner referrals (20%). A larger proportion in the mass radiography group underwent lobectomy than in the other group. The patients with symptoms were usually referred by general practitioners without undue delay, and most resections were performed within the first two months after radiography.

The most disturbing finding was the small number of silent lesions that were discovered by routine mass radiography. This might have been due to radiographic technique, because small peripheral lesions were often not distinct enough to be noted, even by experienced observers, on 35-mm. film. At present both cancer of the lung and active tuberculosis are found predominantly in men over 35, and it is in this age group that the main effort of mass radiography should be concentrated. It is recommended that more 100-mm. x-ray units, with their superior quality and size of film, should be installed to deal with the larger number of patients, particularly men in the critical age group.

Xanthocillin.—The local use of a new antibiotic, xanthocillin, was described by F. R. Bettley (*Brit. M. J.* 1:1226, 1959). Xanthocillin, derived from Penicillium notatum, was isolated in the form of yellow crystals containing two distinct chemical components with similar properties. It is not suitable for systemic use because of its toxic properties and poor absorption, and so it is limited to topical application. In vitro tests have shown that most of the common gram-positive and gram-negative pathogens, including Proteus and Pseudomonas aeruginosa, are sensitive to the antibiotic, which also has some suppressive action on Mycobacterium tuberculosis and some pathogenic fungi and yeasts. Bacterial resistance develops very slowly, and no cross-resistance to other antibiotics has been reported. Patch tests showed no irritating or sensitizing properties. Bettley has treated infected eczematous and intertriginous eruptions with a cream containing xanthocillin. Most of the patients had already been treated with other antibiotics or with antiseptic applications. In no case did the antibiotic act as a primary irritant or sensitizer. In some patients there was a rapid and striking improvement, after other antibiotics had failed, while in others it was of no apparent benefit. The general impression was that the results were favorable, and that a more extensive trial was warranted.

Carcinogenesis and Cosmetics.—In a debate in the House of Lords a member asked if azo or other synthetic dyes were used in lipsticks, whether such dyes were toxic or carcinogenic, and whether any control was exercised over their incorporation into lipsticks. Dyes are in fact used in lipsticks, and they may be absorbed by ingestion or through the skin. There is no control over their use, as there is in the manufacture of foodstuffs. Thirty synthetic colors are allowed as additives to food, but none are known or suspected carcinogens.. Nearly 200 dyes and pigments are used in the cosmetics industry, excluding those used in hair dyes. It is suggested that only certain dyes should be used in the manufacture of cosmetics. This would reduce any carcinogenic hazard. Apart from dyes estrogens are sometimes added. These are known to cause cancer in animals and probably in man. Unlike substances having a direct toxic action the estrogens are only carcinogenic when used for 20 years or more. Other toxic results such as dermatitis make their appearance within a short time. There is much to be said for controlling the constituents of cosmetics and insuring that no known or suspected carcinogenic agents are used in their manufacture.

Too Little Spent on Medical Research.—At the annual meeting of the Royal Society of Health, Lord Cohen of Birkenhead, its president, said that Britain is spending far too little on medical research. Although much has been accomplished in the conquest of disease, four scourges call for intensive research. These are cancer, heart disease, arthritis, and mental illness. Cancer is responsible for about 20% of all deaths in Great Britain. Coronary disease, strokes, high blood pressure, and other forms of heart disease have accounted for 50%. Many of the most killing forms of heart disease occur among active persons in their 40's and

50's. Rheumatism, while not a fatal disease, is a major cause of disability. It is disconcerting to reflect that half of the total hospital beds in the country are occupied by patients suffering from mental illness. Thus 1 in 250 of the population now occupies a bed in a mental hospital. Research requires not only new ideas but also money. Intelligent expenditures for research are limited by the number of men and women of sufficient quality and dedication who can be found to do this work, but even so, said Lord Cohen, we could and should spend far more than we do.

Working Women.—At the same meeting Dr. Alice M. Stewart said that modern society was ill-adapted to the needs of women over 40 years of age. She opposed the notion that woman's place is in the home and added that one could as well say, "Man's place is behind a wheelbarrow." On the other hand the most contented mothers and wives are the ones who have succeeded in combining housework with other occupations. More day nurseries are needed so that young mothers can go out to work. Some of them could run the nurseries.

Drug Output Doubled.—Britain's drug industry is expanding. Output and exports have more than doubled since 1948, yet the increase in labor has been less than 10%, according to the annual report of the Association of the British Pharmaceutical Industry. Sales to the National Health Service (NHS) accounted for only about 33% of the industry's output. Australia was the chief overseas buyer, followed by Nigeria, New Zealand, and the Union of South Africa. Throughout the past 10 years the cost of drugs has loomed large in Parliamentary and public discussions of the NHS, although manufacturers and wholesalers still receive no more than 7% of the total NHS expenditure. There is a need to assemble facts about the provision and use of drugs, particularly the savings to the NHS and the economy at large which the use of modern drugs produce, so that the question of NHS expenditure on drugs can be viewed in its true perspective. Members of the association informed the committee of the British association that they would welcome the adoption of the metric system in Great Britain and could implement it within a year. Most members also favored a decimal monetary system.

Mental Health.—Mr. Walker-Smith, Minister of Health, called on county and borough councils to expand their mental health services to meet the new concept of care of the mentally disordered in the community, as far as possible, rather than in hospital. The new order will require close cooperation among the hospital, local health officers, and family doctors. When more of the mentally disordered are being helped to live independent and useful lives in the community, more will remain under the care of family doctors. In the treatment of mental patients three principles that are sometimes in conflict must be balanced: the patient's treatment, the patient's liberty, and protection of the community. Local health authorities are urged to provide training centers for mentally disturbed children up to the age of 16 years, who are regarded as suitable for training. These children should live at the center from Monday to Friday, or for a school term, returning home at week-ends or during holidays. There should be regular medical inspection, dental treatment, meals, and milk provided on lines similar to those in schools for normal children. Adult training centers are also needed but should be given a lower priority.

Luminous Watch Dials.—At the same meeting Sir Ernest R. Carling said that a Swiss firm was using radioactive strontium to luminize watch dials. This is known to have done serious harm to one wearer. These watches may be bought in Great Britain.

Tetanus from Wound Dressings.—After the occurrence of five postoperative cases of tetanus within a fortnight in one hospital the Medical Research Council requested the Public Health Laboratory Service to investigate possible methods by which infection with tetanus spores might be conveyed in hospitals. The study was made by 14 laboratories. All the materials commonly used for wound dressings were examined by boiling samples with nutrient broth. This kills all organisms except tetanus spores. Growths surviving this procedure were then subcultured on slopes of horse blood agar and confirmatory tests of identity of Clostridium tetani were made. Cl. tetani was found in samples of absorbent cotton, gauze swabs, and stockinet. The most frequently contaminated form of dressing was unbleached absorbent cotton; 100 samples of this were examined in various parts of Great Britain and tetanus spores were found in 20.

On the other hand only one packet in 122 of bleached absorbent cotton was found to contain the spores. The use of unbleached cotton would explain outbreaks of tetanus infection in hospitals where in other respects every attempt is made to preserve sterility. It is therefore recommended that all dressings and particularly absorbent cotton be sterilized before being taken into the operating rooms. Other possible sources of infection were investigated. Tetanus spores were found in the air intake ducts and in the wall plaster of operating rooms. Rubber gloves were not examined, but it is well known that they may be dusted with potentially contaminated powder and are by no means always properly sterilized. It was concluded that every attempt should be made to prevent tetanus spores being carried into the operating room by air, street dust, dressings, or any other route.

CORRESPONDENCE

OXYGEN IN THE THERAPY OF CYANIDE POISONING

To the Editor:—During experiments on sublethal intoxication of rats by intravenously given potassium cyanide (Levine and Wenk, *J. Nerv. & Ment. Dis.*, to be published), slightly more cyanide was required to induce brain lesions if oxygen was administered than if the experiment was conducted in air. Further work on mice showed that the LD_{50} of potassium cyanide was slightly increased (10 to 20%) by administration of oxygen; survival time after fatal doses was increased also. These results suggested the possibility that oxygen might be useful in the therapy of cyanide poisoning.

Textbooks on pharmacology and toxicology advise the nitrite and thiosulfate method of Chen and Rose (J. A. M. A. 149:113, 1952; 162:1154, 1956) as the treatment of choice. In most textbooks oxygen is not mentioned or is advised only when respiration has ceased and artificial respiration is required. Salter (Textbook of Pharmacology: Principles and Application of Pharmacology to the Practice of Medicine, Philadelphia, W. B. Saunders Company, 1952) stated that the rationale for the use of oxygen was not very sound because cyanide produces a histotoxic anoxia in which tissues are incapable of utilizing oxygen. Locket (Clinical Toxicology: Clinical Diagnosis and Treatment of Poisoning, St. Louis, C. V. Mosby Company, 1957) went further and stated: "If a cyanide has been taken do not waste time with . . . artificial respiration or administration of oxygen." However, Sollmann (Manual of Pharmacology and Its Applications to Therapeutics and Toxicology, ed. 8, Philadelphia, W. B. Saunders Company, 1957), referred to the work of Gordh and Norberg (*Acta physiol. scandinav.* 13:26, 1947) who found that rabbits in a preterminal state of poisoning after receiving lethal doses of cyanide could be saved by oxygen.

Ferraro and Kilman (*Psychiatric. Quart.* 7:115, 1933) and Jervis (*Riv. pat. nerv.* 50:410, 1937) stated that cyanide poisoned cats were revived by oxygen. Ferraloro (*Sperimentale* 84:115, 1930) reported that survival of cyanide-poisoned guinea pigs was prolonged by increased oxygen tension. Wirth (*Zentrabl. f. Gewerbehyg.* 24:258, 1937) found that oxygen speeded the recovery of cyanide-poisoned cats and rabbits, and carbon dioxide was not indicated. Paulet (*Arch. internat. physiol.* 63:340, 1955) found that oxygen saved dogs that had received lethal doses of cyanide, and its effect was even greater when given under slightly increased pressure. H. J. Taylor (personal communication) was able to save cyanide-poisoned cats by inducing a high-pressure oxygen convulsion!

Breathing pure oxygen increases the arterial saturation of hemoglobin above the normal 97.5% level and increases the amount of oxygen physically dissolved in plasma, the two mechanisms [illegible] oxygen by 11% (Comroe and [illegible] Basis for Oxygen Therapy, Springfield, Ill., Charles C Thomas, Publisher, 1950). Paulet attributed the beneficial effect of increased oxygen transport to augmentation of that small proportion of cellular respiration which is independent of cytochrome oxidase (the enzyme inhibited by cyanide). Even if the metabolic effect of oxygen is small, it may prolong life enough to give detoxification mechanisms (natural and therapeutic) a chance to operate.

Oxygen is a readily available therapeutic agent, and its use in cyanide poisoning should not be neglected. *Probably it should be used even after* administration of nitrites and thiosulfate, as the methemoglobinemia induced by this treatment re[illegible] blood to carry oxygen to the brain.

FORMATION OF LIPIDS

To the Editor:—The paper by Holman, McGill, Strong, and Geer in The Journal, May 23, page 416, presents evidence for the local formation of lipids rather than filtration into the arterial bed in the pathogenesis of arteriosclerosis. The cause is ascribed to special manufacture by the local cells for lipids as well as enzyme-hormonal influence. The fatty streaking in human arteries is considered the earliest stage of the arteriosclerotic process. They, however, ignore physical causes considered by previous investigators, particularly Moschcowitz, who stressed the importance of a combination of factors of which the most important are the prolonged normal intravascular pressure plus perivascular resistance. Vascular constriction is another factor affecting local resistance. I have shown (*Angiology* 6:556-566 [Dec.] 1955) that this results in intimal proliferation followed by fibrosis, thrombosis, infarction, and gangrene—the second, third, and fourth stages according to Holman and associates. I suggested that the early pathological changes in the vessel resulted from a local ischemia due to the pressure. Whether the lipid formation resulted from this ischemia is conjectural. From the lipid streaking concentrated around the ostia of the branches of the aorta, as illustrated in the article of Holman and his group, one may reasonably conclude that lipid formation or infiltration favors areas under increased pressure and resistance.

NOCTURNAL HABITS OF SNAKES

To the Editor:—In The Journal, May 16, 1959, pages 268 to 272, is a good article by McCreary and Wurzel on poisonous snake bites. On page 270 is a puzzling statement that "All the Crotalidae are front-fanged serpents, generally nocturnal in their habits, and usually capable swimmers."

I am in my late 60's, have lived all my life in what may be correctly called rattlesnake country, and have seen many rattlesnakes in their natural habitat. I have heard accounts of persons sleeping on the ground at night and being bitten by rattlesnakes, but I have been unable to obtain verification of any such account. Especially in this western country it has been my observation that the rattlesnake stays in the relatively cool shaded areas during the hotter portion of the day. Especially at altitudes above 2,000 ft., the nights are frequently quite cool and snakes become lethargic. I would appreciate a comment on this alleged nocturnal habit of rattlesnakes, since the quoted statement is contrary to my experience.

John H. Schaefer, M.D.
1525 S. Broadway
Los Angeles 15.

The above comment was referred to the authors of the article cited, and they have submitted the following reply.

To the Editor:—Mr. Roger Conant, curator of reptiles at the Philadelphia Zoo, tells us that most of the rattlesnakes in the humid East and Southeast become nocturnal during very hot weather. They remain hidden during the daylight hours and do their prowling and hunting after the ground and air have cooled. The situation is somewhat different in the arid regions where the temperature rises very high during the daylight hours, especially when there are no clouds. In these regions temperatures tend to drop considerably at night, and this is especially true at higher altitudes. Nocturnal temperatures in these areas may be too low to stimulate the snake into activity. However, Mr. Conant tells us that the herpetologists who live in the West say that it is most unusual to find rattlesnakes about at any time of the day except in the spring of the year when they have recently emerged from hibernation, when they are hungry, or when the mating instinct is strong and when temperatures in the sun are not too severe. We would assume that much of Dr. Schaefer's experience with rattlesnakes has been in such arid country.

MISCELLANY

RETIREMENT CRITERIA FOR PHYSICIANS

Norman L. Goldberg, M.D., St. Petersburg, Fla.

Dissociation from medical practice, with its implications of retirement and leisure for the physician, presents a problem that has been discussed too infrequently in our medical journals. Yet it has become a dominant conversational topic among colleagues in hospital lounges as well as interdepartmental and intradepartmental staff members of our institutions for medical teaching. The majestic attraction of the word "retirement" approaches in popularity the term "baseball" in gatherings of seasoned physicians; their conversations are frequently threaded with attempts at solution. Indeed, free discussions concerning retirement have their embryonic origin not infrequently at such early stages as the resident training period.

Usually before middle age, and sooner rather than later, the physician becomes confronted with the problem of desire for voluntary separation from professional duties, assuming he survives long enough. As life expectancy has become lengthened, more physicians face the decision of retiring voluntarily. Today's influences on the industrial worker, the corporate executive, and the organizational employee are each receiving extensive sociological study concerning their retirement problems. Research studies applicable to the intrinsic pressures on our medical member groups have been deprived of parallel investigation or attention. It should suffice to point out that physicians affiliated with medical educational and veterans' facilities; the departments of the Army, Navy, and Air Force; and medical departments of industry, in many instances, retire mandatorily at a fixed age, usually 65 years. Hence the even greater importance of the problem when applied to the self-employed and unregimented individual practitioner or specialist.

Are there basic criteria, direct or implied, that should apply to careful short-range or long-range planning for retirement? What might they be? Should our thinking be schooled in a philosophy toward this end? And can one justifiably enumerate a few fundamental, nontheoretical reasons for separating oneself from the wear and tear of application to patient care? Should the selfish interests of oneself and dependents, after prolonged educational and specialized training periods, influence one's decision?

Answers to these questions require medicosocial investigation into today's society, in the conservation of our store of specially trained manpower, and in the "carnival of economic change." Attempts on the part of the individual doctor to resolve his personal basic requirements leave him confused, insecure, and engulfed by "the doctor's dilemma." Common sense dictates that a plan be designed to provide comfort in retirement for the physician and his family. In essence his spiritual, mental, physical, and financial prerequisites must be satisfactorily fulfilled. Preparations excluding these provisions lead to pathetic degenerative parasitism not alone for the physician but equally shared by his dependents.

Let us divert our thinking for the moment from leisure substitutes, programs for retirement, and those philosophical and compensatory pleasantries which may precede or follow cessation from active practice, and confront ourselves with a few of the basic criteria for retirement.

Proverbial Routine

Unfortunately, soon after launching into active practice, the enthusiastic young physician, conscientious, forthright, and usually married and with dependent children, begins to establish a "way of medical life." Customarily, this pursues a day-to-day pattern, relatively invariable, which with seasoning and maturity inadvertently blends into a characteristic over-all repetitiousness. In due time, varying degrees of deviation from this rather set "design for professional living" produce irritability toward his family, inducing an obvious restlessness of manner and often developing into an intermittent feeling of "internal jitters." By contrast, however, a conscientious stability with external charm, warmth, and gentleness toward patients always appears on the surface, evidenced by the physician's well developed and stylistically accomplished art of handling patients.

Thus with longevity in practice, exposed as it is to fluctuant influences, there develop deep, conflicting urges to divorce oneself from medical work. This may well approach a status inconsistent with the maintenance of smooth, balanced, and integrated behavior which is required by physical, mental, and emotional demands. Such wavering compulsiveness, once established, points toward the need for retiring. Should this compulsive determinism remain unbroken, it likens the physician to a soft-shelled crab exposed to a shark; and involuntary retirement becomes imminent. This need for separation from professional duties becomes conclusive when test instances of repeated vacations fail to alleviate the compulsion.

Predisposing Tensions

In contemporary medical practice, whether institutional, industrial, or individual, subjective pressures, either intermittent or sustained, are invariably present. These may be termed intangible pressures and may be enumerated: competitive influences, hurried medical life, desire for making and sustaining professional and other contacts, civic activities, social impositions of family life, and religious participation. Of perhaps even greater import is the universal problem of a physician's becoming overtaxed by patient load; and, more important, his dedication dictates that he play the role of "Lord Bountiful" to their abundant and varied personal problems. Other pressures are too numerous to relate. Their cumulative sequelae over the years, despite the transient forgetfulness and dilution afforded by relaxation and infrequent vacations, precipitate uncontrolled inner tensions. Should these tensions rise above the level of the physician's subconscious, they disturb his behavior pattern. Frequently objective behavior changes are detected by his colleagues and eventually become apparent to members of his family. Uncontrolled tensions, sustained and manifest, are of paramount significance in determining the need for retirement.

Prophetic Planning

Men of medicine as educators, practitioners, or trained specialists become individualists and nonconformists in their thinking and in their methods as well as in their aspirations. Yet lurking in their mental recesses is a uniformity of thought concerned with the sunset of their days, far off on the visible horizon of life. Whether the young or old physician smokes a pipe, cigar, or cigarette (filtered or otherwise), a plan for retirement presents one sphere of thought in which self-initiated, unadulterated, and filtered thinking must be unique and exclusive unto himself. This point I wish to emphasize and make unmistakable.

The planning of a retirement program cannot begin too early in the life of the practicing physician. Formulation of a prudent, adjustable arrangement, within the framework of an established program, is not only desirable but essential to our changing times. Nevertheless, flexibility within a program adaptable to current changing personal and family conditions should be decided on free from contaminating influences. Conclusive advice should not be sought from medical colleagues, lawyers, accountants, bankers, insurance or stock brokers, estate analysts, and consultants, nor, above all, from successful acquaintances and patients. One's projected plan should be constructed on one's own thinking and by oneself alone. (Naturally, this statement should not be construed to exclude periodic and frequent discussions between the physician and his wife or other vitally concerned members of his family. It also does not preclude a full understanding and familiarity with reliable source material on all forms of investments, such as insurance, real estate, stocks and bonds, and business investments.) Fewer errors of judgment compatible with one's ultimate needs are likely to occur.

The physician alone is cognizant of the interplay of his emotional, social, economic, and familial requirements. Not only for the present but also for the future must he assert an imaginative daring in planning fulfillment of his varied needs. Because the physician and his family are to become the recipients of benefits derived from such an attitude, he must remain a consistent thinker. His lack of prior business training and acumen presupposes that he now develop new initiative and creativity. A term well suited for such a premeditated plan as described, I like to think, is "organic planning with flexibility." To better understand and appreciate "organic planning with flexibility" let me paraphrase and interpret. In principle, one's program should not be composed of separate and unrelated forms, fragments, or parcels of investments, but rather it should be a plan in which each and every investment is likely to appreciate and grow logically as a consequence to prior ones. Such planning should possess adequate diversification and be amenable to reanalysis and reevaluation, since from time to time new and added personal requirements occur.

Once established, a program should be adhered to with tenacious loyalty, free from divergence and manipulation with a speculative tinge. Patient long-range fidelity to a carefully selected program will yield for the physician pride of accomplishment, enhancement of content, and a paradoxical improvement for solving old and new problems.

Perception and Conditioning

Assuming a flexible and organic retirement program has been patterned to his needs, the physician should begin to anticipate his expected severance date from practice. This should be established sufficiently in advance to allow him to prepare himself. Essentially when should such preparation begin, and in what should it consist?

Adequate security from financial returns, undoubtedly basic and essential, is of no greater importance to the physician than the conditioning of his outlook and thinking after actual cessation from medical practice. The amount of time to spend on such preparatory effort not only is distinctly individual but should result exclusively from personal soul-searching and self-analysis. Progress along this line is slow and often discouraging. However, for practical purposes, no less than several months to two years or longer should be spent on this matter in advance of the projected date of retirement.

A detailed and analytic outline of the characteristic intricacies and peculiarities of the physician's way of life in practice must be carefully thought out. This is as diverse as the many races, cultures, personalities, and folkways comprising the fundamental moods, moral views, and customs of any group. This can and must be accomplished by the physician with little outside help, preferably on his own and through persistent effort. The younger the retiring physician the easier it becomes for him to establish with facility a contented attitude toward his expectations on his retirement. The more completely one can detach his emotional attitude from his practice the better is he conditioned for retirement. Let me assure you that any degree of discontent experienced after retirement from active practice will be fleeting, despite one's apprehensiveness. The ultimate attainment of proper adjustment is wholly dependent on conquering and eliminating certain attitudes toward oneself, family, and patient acquaintances. The periodic essays appearing in The Journal in the "Leisure Corner" department have been beneficial from this point of view.

Leisure Substitutes

Customarily, the newly retired person faces a brief transitional period after cessation from prior activities. As a former practitioner one is usually dismayed and bewildered in spite of the apparent perfection with which he is conditioned to his new anticipations. With courage he should be ever conscious of the presence of a silvery lining beyond each seemingly endless but passing cloud.

Generally, the physician has made plans for a brief or prolonged vacation to forestall this period. There may or may not be a preplanned removal of his family to begin a new life in an entirely new place. Whatever the selection, the once feverishly occupied life of a doctor must become transformed into a tranquil, unrepressed new life.

The diverse activities which intelligent members of our profession can choose are too numerous to tabulate. Blessed with wisdom and interesting temperaments, our colleagues are fit for any one of many leisure substitutes. One may choose among indoor and outdoor activities, cultural enjoyments, travel interests, civic and club participation, medical research, reading, writing, religious activities, and a family togetherness heretofore but incompletely enjoyed. The adoption of any one or more of these as a pastime will offer companionship and camaraderie that will become enjoyably time-consuming; and, above all, the physician will enjoy a general well-being, emancipated from his professional concerns.

For you, yesterday's and today's sameness of life in medicine will move unruffled into tomorrow's bountiful life. As an advisor to sufferers of mankind, countless blessings can be yours for the seeking; for what seemed a difficult challenge now becomes eased by gracious acceptance. To you will be offered contentment and serenity as a new and hopeful paradise unfolds.

MEDICAL LITERATURE ABSTRACTS

INTERNAL MEDICINE

Diuretic Effect of Steroid Therapy in Obstinate Heart Failure. J. N. Mickerson and J. Swale. Brit. M. J. 1:876-883 (April 4) 1959 [London].

The authors report on 4 men and 9 women, between the ages of 41 and 82 years, with refractory congestive heart failure who were treated with prednisolone at the Charing Cross Hospital in London. Clinical observations suggested an initial coexistent endocrine overactivity followed subsequently by adrenal cortical insufficiency. This premise was supported by the presence of hyponatremia, a normal or elevated serum potassium level with an increased blood urea in these patients with chronic heart failure, which had become resistant to therapy with digitalis, a low-salt diet, and diuretics. The urinary excretion of 17-ketosteroids was estimated in 4 of these patients, and in 2 the corticoid excretion was also assessed. Subnormal values were obtained in each patient, and in one they were consistent with a diagnosis of Addison's disease. After administration of corticotropin the urinary excretion of these adrenocorticoids increased in each patient and was accepted as evidence that hypoadrenocorticism was due to failure of the anterior pituitary rather than to adrenal cortical failure.

Replacement therapy with prednisolone given in doses of 5 mg. 3 times a day for the first 24 to 48 hours, followed by a maintenance dose of 2.5 mg. 2 or 3 times daily, greatly enhanced response to diuretics in all 13 patients who received this treatment. All were relieved of congestive heart failure and also, when coexistent, of left ventricular failure. Two patients died of pulmonary embolism after 1 and 2 weeks of prednisolone therapy respectively. These results, considered in conjunction with those previously recorded in patients with congestive heart failure, suggest a pattern of events contributing to the formation of edema. The pituitary-adrenal mechanism, already fully extended in response to congestive failure, becomes exhausted, antidiuretic hormone overactivity persists, and water retention occurs, with resulting tissue fluid hypotonicity. It is unlikely that the diuresis induced by prednisolone was due to increased urinary loss of sodium, since all the patients had a decreased serum sodium level before the institution of steroid therapy, and the serum sodium concentration increased and remained at a normal level despite a profuse diuresis. It must, therefore, be assumed that the increased urinary output was due to a predominant water diuresis. Parallels are drawn between the edema of late-stage congestive heart failure, nephrotic edema, and starvation edema.

Streptococcal and Non-streptococcal Sore Throat. V. Esmann. Acta med. scandinav. 163:265-276 (no. 4) 1959 (In English) [Stockholm].

Sore throat is a frequent symptom in several common acute infections, such as streptococcic infections of the pharynx, diphtheria, mononucleosis, Vincent's disease, influenza, or primary atypical pneumonia. In addition, the group of so-called undifferentiated acute respiratory diseases sometimes presents a clinical picture which may readily be mistaken for a streptococcic sore throat. It has been demonstrated that the new virus group (adenovirus) is responsible for a large proportion of these cases. In an attempt to elucidate how often such infections are due to beta-hemolytic streptococci or how often they may be ascribed to other causes, the author made studies on 81 patients who were acutely ill, with a sore throat as the predominant symptom. The series originated from the clienteles of 20 general practitioners. Pharyngeal material was obtained by rubbing a sterile cotton swab against the tonsils, the soft palate, and the oropharynx. The streptococci were identified by their colonial morphology and their ability to produce beta-hemolysis on blood-agar plates. Both doubtful and typical colonies of streptococci were isolated and studied for group and T antigens. The antistreptolysin titer (AST) was determined by the method of Kalbak. The antistreptococcic-hyaluronidase titer (ASH) was determined at the Danish State Serum Institute by the turbidimetric method of Faber.

Growth of streptococci was obtained in 34 (or 42%) of the patients. An increase in AST was found to be a significant sign of streptococcic sore throat, when this increase amounted to 100% of the initial AST, and when the convalescent-phase titer exceeded 1:100. An increase in the ASH was found to

The place of publication of the periodicals appears in brackets preceding each abstract.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover 1950 to date only, and no photoduplication services are available. No charge is made to members, but the fee for others is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

be a significant sign of streptococcic sore throat, when the convalescent-phase titer exceeded 1:9000. A significant increase in one or both antibodies was revealed in 62% of the patients. A significant increase in the antibody formation against adenovirus occurred in 3 patients with sore throat, and a questionable increase was seen in 1 patient. One of the significant increases occurred in a patient with mononucleosis who may have had a superimposed adenovirus infection. The Paul-Bunnell test showed definitely increased titers in 6 patients with sore throat, who all revealed hematological findings characteristic of mononucleosis. Smears of necrotic tonsillar tissue from 2 patients with Vincent's disease showed fusiform bacilli and spirilla in large numbers. Forty-four per cent of the 81 patients with sore throat had to be classified as having undifferentiated respiratory disease. Like most other investigations this study showed that streptococcic and nonstreptococcic sore throat cannot be differentiated on the basis of clinical observations, except that the absence of redness of the fauces suggests that the case is of nonstreptococcic origin. The bacteriological study of pharyngeal flora not only is of great diagnostic importance but also is a valuable aid for therapy.

Survival in Acute Myocardial Infarction: Factors Observed in 318 Patients. E. E. Harnagel, V. V. Jelinek, A. A. Andonian and C. W. Ulrich. California Med. 90:264-267 (April) 1959 [San Francisco].

Factors influencing mortality were studied in 318 patients with acute myocardial infarction, admitted to the California Hospital in Los Angeles during 1949-1951. There were 228 men and 90 women, ranging in age from 33 to 86 years. The average age of the men was 60 years, and of the women 65½ years. The mortality in women was 44.4%, in men 39.5%, and in the total series 41%. The death rate increased with the age of the patient. Twenty-six per cent of all deaths occurred within the first 24 hours, 44% within 72 hours, and 71% within the first week after hospital admission. Increased mortality rate was associated with previous history of congestive failure, myocardial infarction, hypertension, or cardiomegaly. Among the circumstances immediately preceding infarction, only surgical operation or massive hemorrhage (usually gastrointestinal) appeared to influence the outcome. Not only the presence but also the degree of shock, congestive heart failure, cyanosis, and dyspnea adversely influenced the chances of survival. Duration, location, radiation, and number of attacks of pain did not seem to be associated with extraordinary mortality rates. Patients with anterior infarction, particularly if it occurred at the septum, had the poorer prognosis. The prognosis was likewise poor in those with combined anterior and posterior infarctions. Thromboembolic complications and certain disorders of rhythm and of conduction definitely worsened prognosis. The authors emphasize the necessity of classifying acute myocardial infarction for prognostic purposes, which not only would increase knowledge of the history of the disease but also would supply valuable control data for future investigations of therapeutic agents.

Reversal of Tuberculin Reaction in Early Tuberculosis. J. M. Adams, V. A. Kalajan, B. O. Mork and others. Dis. Chest. 35:348-356 (April) 1959 [Chicago].

The authors report on 160 persons with a previous negative reaction to the tuberculin skin test, in whom the reaction turned to positive (converters). They were divided into 3 groups: Thirty-five (group A) were infants, aged less than one year, who were assumed to have had a previous negative skin reaction because of their age; 87 (group B) were persons who had turned from negative to positive within 3 months; and 38 (group C) were those who had done so within 12 months. Of the 160 persons, 121 (28 of group A, 69 of group B, and 24 of group C) were then followed by repeated tuberculin tests for signs of change in their reactions to the tuberculin tests. Sixty-eight (56%) of the 121 persons showed a change in their skin reactivity from a positive to a negative reaction (reverters). Of these 68 persons, 17 (60%) belonged to group A, 40 (58%) belonged to group B, and 11 (46%) belonged to group C. By arranging the 68 persons according to the degree of their skin reactivity, it appeared that the ratio of reverters was 76% among those with a reactivity of 1+, 50% among those with a reactivity of 2+, 38% among those with a reactivity of 3+, and 17% among those with a reactivity of 4+.

The reasons for this surprisingly high rate of change are unknown, but it may represent early detection of tuberculous infection in persons who might otherwise go unrecognized at this stage of their disease. By repeated skin testing of persons with known negative and positive reactions to the tuberculin test, the natural history of tuberculosis may become better understood. Roentgenologic studies were performed on 97 persons in this series and revealed a direct relationship of the findings with the degree of change in tuberculin reactivity. The persons with negative chest roentgenograms showed a high rate of reversal; in contrast, no change in skin reactivity was found when the roentgenologic findings indicated a "presumably active" lesion.

When guinea pigs, inoculated with strains of mycobacterium tuberculosis, were treated with isoniazid, their skin reactivity to tuberculin was reduced as compared with that of untreated control animals. If treatment was begun at the time of inoculation, some animals failed to have a positive reaction, and all had negative cultures. If treatment was delayed, all had positive reactions to the skin test, and a few showed signs of tuberculosis at autopsy and by culture.

The Incidence of Cancer in Chronic Leukemia and in Polycythemia Vera. J. H. Lawrence and W. G. Donald Jr. Am. J. M. Sc. 237:488-498 (April) 1959 [Philadelphia].

A review of the literature and of a series of cases of primary malignancy occurring in patients with chronic lymphatic leukemia, chronic myelogenous leukemia, and polycythemia vera suggests an increased incidence of cancer in these conditions. In leukemia, there is no indication from reported cases of a predilection for any specific organ or system. With polycythemia vera, however, there is a high incidence of renal malignancy—17 cases in 630 patients; but aside from the kidney no apparent close association with an organ has been observed. The role of radiation therapy in the production of associated malignancies is not clear. In the authors' own series and in other reported series of patients with polycythemia vera, there has been no indication of an increase in malignancy in the radiation-treated group as opposed to the group treated by other methods, but the number of patients is not large enough for adequate comparison. No series of untreated patients with leukemia is available for analysis, but in the experience of the authors and in reports in the literature there is no indication that radiation in these patients has produced malignancy. In agreement with the experience of others, the authors found that patients with polycythemia vera and with chronic leukemia have an increased susceptibility to malignancy, but this susceptibility is not produced by radiation therapy.

Phenethylbiguanide in Diabetic Patients: Clinical and Metabolic Effects. T. H. Lambert. California Med. 90:257-260 (April) 1959 [San Francisco].

A new nonsulfonylurea, hypoglycemic compound, phenethylbiguanide (N'-betaphenethylformamidinyliminourea hydrochloride [DBI]), was given orally to 70 unselected and nonobese patients with diabetes mellitus. There were 34 males and 36 females, ranging in age from 6 to 84 years. The patients were studied for periods which varied from 7 days to 16 months; 53 were hospitalized, and 17 were outpatients. Their diabetic condition had existed from 1 year to 29 years, the average duration being 10.6 years. All the patients had been observed while being treated by diet alone, or by diet and insulin. The dosage of phenethylbiguanide varied; adults were given at the beginning 150 mg. and children 75 mg. of the drug in divided daily doses. An adequate control of diabetes was obtained with phenethylbiguanide alone in 27 patients, ranging in age from 40 to 73 years. These patients required 50 to 225 mg. of the drug daily. In 10 of them side-effects, such as anorexia, nausea, vomiting, or diarrhea, appeared 1 or 2 weeks after treatment was started. These effects subsided in some despite continuation of treatment, and in others after a temporary reduction of the dosage.

Treatment with phenethylbiguanide was discontinued in 12 patients because of untoward manifestations attributed to ketosis or to irritation of the gastrointestinal tract or to some unknown cause. Whether the phenethylbiguanide tablets were given before, during, or after the meals, or whether antispasmodics or antacids were given before or after the drug did not seem to influence these unpleasant symptoms. A more stable control of diabetes was maintained in 11 patients with the combined administration of phenethylbiguanide and insulin. Two patients in whom the disease was well controlled were lost to observation, and in 18 the drug had no demonstrable hypoglycemic action. However, no evidence of serious toxicity was demonstrated in clinical and metabolic studies; there was no impairment of liver or kidney function; and no changes were seen in repeated hematological studies after the administration of phenethylbiguanide.

The Primary Mortality and the 5-Year Prognosis of Cardiac Infarction: A Study Which Considers in Particular How the Prognosis Is Affected by the Composition of the Material as Regards the Age and the Sex of the Patients and the Severity of the Infarction. S. Helander and M. Levander. Acta med. scandinav. 163:289-304 (no. 4) 1959 (In English) [Stockholm].

This report is concerned with 286 patients, 173 men and 113 women, who were treated for their first attack of cardiac infarction at the Karolinska sjukhuset, Stockholm, during the years between 1940 and 1949. The aim of the investigation was to study some of the factors in the composition of the case material which could influence the primary mortality and the long-term prognosis of patients with cardiac infarction. For this reason the patients were classified with regard to age, sex, and severity of the first attack of myocardial infarction. As regards the severity of the attacks, patients showing the clinical picture of shock, with a marked fall in blood pressure in the first days of illness, were classed under group 1. Those manifesting no shock but otherwise presenting the complete picture of cardiac infarction, with fever, raised erythrocyte sedimentation rate, and leukocytosis, were classified as group 2. Those with milder cases, in which only electrocardiographic tracings showed evidence of cardiac infarction, were classified as group 3. The primary mortality was 54% in group 1, 27% in group 2, and 4% in group 3. The difference in the primary mortality in relation to age and sex of the patients was most clearly marked between the older and the younger women (48 and 6% respectively). It was postulated previously that women have a higher mortality than men; this seems to apply to older women only.

For the estimation of the 5-year survival rate, the authors had at their disposal the records of 232 patients. Fifty-eight per cent were still alive after 5 years. The severity of the infarction did not influence the continued course as markedly as it did the primary mortality (50% survivals in group 1 against 62% in group 2; the difference is not statistically significant). It is noteworthy that in group 3 the 5-year survival rate was as low as 42%. The difference in the primary mortality between the younger and the older women was not matched by a similarly marked difference in the 5-year survival rate (62 and 49% respectively). A comparison between the 5-year survival rate of patients after the first attack of myocardial infarction, on the one hand, and of the population of Stockholm of a comparable age, on the other hand, showed a markedly increased mortality among the former. There was thrombosis in the coronary artery in 42 of 80 cases studied at autopsy, and coronary embolism in 1 case.

The electrocardiographic records and the postmortem findings showed good correlation with regard to the localization of the infarction. Electrocardiographic evidences of atrioventricular and of intraventricular heart block were indicative of a poor prognosis, inasmuch as these patients had a primary mortality of 69%, compared with 23% for patients in whom electrocardiographic tracings did not show such changes. Of 135 patients who survived 5 years after the infarction, 85 were still alive an average of 8½ years after the primary infarction. Examination of 78 of these patients revealed that 21 could maintain a normal activity, 34 had a lowered capacity, and 23 were invalids. Fifty-four patients were troubled by angina pectoris, but it was mild in 9 of them.

Kartagener's Syndrome in Identical Male Twins and a Female Sibling: Report of Cases, with Comments on Pathology and Familial Manifestations. L. S. Safian and F. B. Mandeville. J. Florida M. A. 45:1143-1148 (April) 1959 [Jacksonville].

The authors report the occurrence of Kartagener's syndrome, a triad consisting of situs inversus with bronchiectasis and paranasal sinusitis, in 2 34-year-old men who were clinically identical twins and in their 32-year-old sister. There were 4 other siblings, 2 brothers and 2 sisters, who were all reported to be in good health. The father of the 7 siblings had had diabetes and had died of a heart attack. The mother was alive and well. The bronchograms of the 3 patients showed evidence of bronchiectasis, and multiple roentgenographic views of paranasal sinuses showed clouding of maxillary antrums and other sinus groups; frontal sinuses were rudimentary or absent. All 3 patients had complete transposition of viscera. Seven other instances of family groups presenting multiple siblings with Kartagener's syndrome were collected from the literature.

The occurrence of Kartagener's syndrome is here reported for the first time in clinically identical twins. The syndrome is briefly discussed in some of its pathological and clinical aspects. The seriousness primarily of the bronchiectasis is stressed, and the importance of its early recognition among patients with visceral transposition is emphasized. The factor of familial occurrence is pointed out.

Diagnosis and Treatment of Acute Renal Failure: Experience from a Series of 56 Consecutive Cases of Acute Anuria. A. P. Skouby. Acta med. scandinav. 163:277-287 (no. 4) 1959 (In English) [Stockholm].

The underlying mechanisms of acute renal failure (shock kidney) are inadequately understood, and the results of treatment have been poor. Shock kidney was defined by Swan and Merril in 1953 as "the clinical syndrome resulting when renal excretory function is rapidly, but temporarily, lost because of alterations in renal circulation and the development of disseminated areas of renal tubular degeneration." The results of studies of 56 patients with acute anuria suspected of having shock kidney are presented. In 37 of these patients shock kidney was demonstrated. A diagnosis of chronic renal disorder was established in 13 of the remaining cases, while electrolyte disturbances and occlusion of renal arteries or urinary pathways were the cause in 6. In 5 of the 37 patients, oliguria was of short duration, and regulation of fluid intake was sufficient, but special therapeutic measures were necessary in 32. In 22 of these patients with an increase of blood urea value to at least 400 mg. per 100 cc. or of plasma potassium level to at least 7 mEq. per liter, indications for hemodialysis existed. It was performed 16 times in 11 patients. In patients requiring special treatment, the primary disorders often persisted and were the chief cause of death in those who died.

The main problem in patients with acute anuria is to distinguish whether oliguria is caused by a primary renal disorder or acute renal failure. Renal biopsy is useful, but complications may occur. Furthermore, acute renal failure as the cause of oliguria does occur in patients with chronic renal disease, as demonstrated in one of the present cases with chronic pyelonephritis and hydronephrosis of the right kidney, whereas in the left only lesions characteristic of acute renal failure existed. Evidence indicating that the limb lead electrocardiogram may be of diagnostic value in the differentiation between primary renal disorder and shock kidney was obtained by the author in 1957, and this was strengthened in the present study. In the patients with acute renal failure a positive after-potential was demonstrated in the limb lead electrocardiogram of two-thirds of the patients at a time when no other influence known to produce the phenomenon was detected and the plasma potassium level was normal or elevated. In contrast, a positive after-potential occurred in uremia due to primary renal disease only under conditions known to produce a positive after-potential, such as hypokalemia, diabetic coma, and after an acute attack of renal stone colic with severe pains and vomiting.

Regarding treatment, the author says that the main problems were to abolish shock, to treat the primary disorder, to administer fluids, minerals, and food, and simultaneously to reduce as far as possible the functional tasks of the kidney. Reestablishment of the circulatory volume in shock seldom was sufficient. Therefore, arterenol infusion was used. Some patients were treated simultaneously with hydrocortisone. The diuresis increased during treatment with arterenol. It is suggested that hydrocortisone may be of value in the treatment of renal failure in patients with severe primary disorders. No ill-effects have been demonstrated. The therapeutic effects obtained are largely dependent on the basic disorders.

A Case Report of a New Serological Pattern in the Rickettsial Group. P. O. Nice and W. L. Beeken. Am. J. M. Sc. 237:474-478 (April) 1959 [Philadelphia].

The case of a 48-year-old woman presenting a rickettsial disease with unusual features is reported. The patient had been well until December, 1955, when she developed dull, persistent frontal headache. During the course of the disease, high complement-fixing antibody titers developed to epidemic typhus soluble antigen (1:1280) and Q fever antigen (1:320). Agglutinating antibodies to Proteus O X 19 reached a high level (over 1:640). No significant complement-fixing antibody titers were obtained with rickettsialpox soluble antigen, epidemic typhus antigen, murine typhus antigen, or Rocky Mountain spotted fever antigen. Serum specimens from 2 dogs in the family household were drawn 8 months after the illness in the patient and were found to have a low titer of complement-fixing antibodies to epidemic typhus soluble antigen and Q fever antigen. This serologic pattern differs from any heretofore documented. The pattern cannot be explained on the basis of any known single rickettsial disease, or even on the basis of 2 concomitant diseases, unless there was failure to develop complement-fixing antibodies to some antigens. The authors believe that this may be a previously unrecognized rickettsial disease in which the causative organism shares antigens with the agents of both Q fever and typhus.

Protracted Forms of Acute Leukosis in Adults. G. Marchal, G. Bilski-Pasquier, G. Duhamel and P. Cornet. Presse méd. 67:447-449 (March 7) 1959 (In French) [Paris].

Protracted forms of acute leukosis in adults are more frequent than is usually admitted. The authors collected the cases of 21 patients, with a survival time of from 8 to 28 months, from 2 series of cases recorded at Paris hospitals. In the first series of 84 cases, gathered at random at the Broussais Hospital from 1951 to 1958, 64 patients died in less than 8 months (56 dying within 6 months), and 20 survived between 8 months and 2 years. One patient in the second series of 22 cases, observed at the Tenon Hospital, survived 28 months. This survival of an athletically built, 23-year-old man shows the importance of health at the initial stage of the disease. Altogether, 24% of the patients survived more than 8 months, and 8% more than one year.

The quality of remissions obtained in patients with protracted forms of acute leukosis was studied from the clinical and cytological standpoints. There were good results in 45% of the cases. A lack of parallelism was noted between the hematological and the clinical conditions in remissions. In the first type of remission, there is improvement from the blood picture and medullary standpoints, but a cytological relapse occurs, accompanied by worsening of the general state, anemia, and hemorrhages. After intensive treatment the clinical state is improved, but the blood and the marrow remain leukemic. In 3 patients satisfactory health status lasted from 3 to 7 months with this type of remission. In the second type of remission, treatment seemed to check the illness, but the blood and especially the marrow remained inundated with original cells. In one patient the clinical state allowed a moderate amount of work for 5 months, and the patient survived a year despite the presence of 30 to 80 blast cells per 100 cc. in blood and marrow. The quality of remissions obtained should have as criteria the duration of survival and the resumption of social activity.

The death of patients with protracted forms of acute leukosis is not different from that of patients with the classic forms. However, sometimes these patients die unexpectedly when their blood and medullary states are reassuring. Sometimes coinciding infectious disease or hemorrhage is the cause, and sometimes a cause cannot be found. Type of treatment and earliness in application have influence. The treatment which has the best chance of prolonged action consists of repeated transfusions, massive corticosteroid therapy at the beginning (1 to 3 Gm. of cortisone per day) followed by continued maintenance therapy, and 3 to 6 months' treatment with mercaptopurine. In milder cases the massive doses of cortisone may be omitted.

Blood Pressure and Obesity. H. M. Whyte. Circulation 19:511-516 (April) 1959 [New York].

Previous surveys have shown that the height of the observed blood pressure and the degree of overweight are related, but excess weight does not necessarily mean excess fat and the possibility of error in the measurement of blood pressure due to variations in the size of the arm has not been excluded. Taking these factors into account, the author studied 100 healthy men, between the ages of 20 and 40 years. Height and weight were recorded; the circumference of the upper arm was measured; the subcutaneous fat (skinfold thickness) was measured at 3 sites (paraumbilical, over the triceps, and over the inferior angle of the scapula); the blood pressure was measured from the right arm; and the serum cholesterol level was determined. The results showed a positive correlation between blood pressure and body weight, other factors being held constant. Obesity (judged by the thickness of the subcutaneous fat) had no apparent influence on blood pressure except insofar as it affected the total body weight. Serum cholesterol concentration was related to age, but not to body weight or obesity. An increase in body weight of 28 lb. (12.7 kg.), without any change in arm circumference, was associated with an increase of 10 mm. Hg systolic and 7 mm. Hg diastolic pressure. The conclusion is that blood pressure is related to weight or bulk of the body, but not to obesity except insofar as it contributes to bulk. Cardiac output seems to be related to surface area which increases with bulk. The blood pressure rises when the augmented cardiac output is forced into an aorta that may not have increased in capacity as the body weight rose. To outgrow one's aorta might be one of the dangers of overeating.

SURGERY

Hypophysectomy for Palliation of Breast Cancer: With Especial Reference to Surgical Technique. N. L. Cobb and W. B. Scoville. California Med. 90:261-263 (April) 1959 [San Francisco].

Hypophysectomy was carried out for palliative purpose in 19 patients with cancer of the breast. All the patients had a striking subjective relief of pain after the operation which appreciably decreased their need for narcotics. Ten patients showed some objective evidence of remission. Five patients were living from 1 to 6 months after the operation; 2 of these were asymptomatic, 2 were improving, and 1 was regressing. Twelve patients were subjected to endocrine therapy or oophorectomy before hypophysectomy; 5 showed no relief, but 7, who benefited from these treatments, had both subjective and objective remission after hypophysectomy. Of the 5 patients who had no remission from either endocrine therapy or oophorectomy, one had relief of pain without objective improvement after hypophysectomy, and one had relief of pain as well as objective improvement after the operation.

The survival time after the operation averaged 19.8 months for patients who had a remission, and 2.1 months for patients who had no remission. The length of time the disease existed before hypophysectomy seemed to be related to the survival time after the operation. Patients in whom remission occurred had had cancer for an average of 4.9 years before hypophysectomy, and those without remission had had the disease for an average of 2.7 years. These facts should be considered in the selection of patients for hypophysectomy. The authors found no correlation between the results of hypophysectomy and other factors, such as age of the patient, cell type of the tumor, response to roentgenotherapy, and extent of the disease.

Surgical Treatment of Neoplastic Processes in the Third Ventricle: Observation of 143 Patients. J. Papo and R. Tritapepe. Minerva chir. 14:128-138 (Feb. 15) 1959 (In Italian) [Turin, Italy].

The authors discuss the treatment of 143 surgical patients with tumor in the third ventricle of the brain. The lesion was in the anterior portion of the third ventricle in 89 patients. The third ventricle was not visible in 21 patients. Extirpation of the tumor was attempted in 17 patients, 3 of whom were operative fatalities. Radical exeresis was performed on 6 patients, 5 of whom had the lesion circumscribed within the third ventricle. Partial resection was made in 5 patients, and surgical biopsy in 3. Operation by the Torkildsen procedure was performed on 51 patients, 9 of whom died within several weeks after the operation. Of 33 patients available for follow-up, 15 died within 5 years after the operation, and 18 are still alive, with varying survival periods up to 9 years. Results of direct surgical attack do not seem to warrant its broad application, except in instances in which such procedure is indicated on the basis of ventriculographic findings. Of 22 patients who received irradiation therapy alone or preceded in a few instances by decompression, 6 are still alive at varying periods exceeding 4 postoperative years. Most of the tumors in the anterior portion of the third ventricle seemed to have grown at a slower rate than those in the cerebral hemispheres.

Fifty-four patients had a tumor in the posterior portion of the third ventricle. Direct attack on the tumor was made in 8 patients. This procedure was subsequently discontinued because of the poor results obtained. Removal of the fluid, followed by irradiation therapy, was instituted in the remainder. Double ventriculocisternostomy by the Stookey and Scarff procedure was performed on 36 patients, 2 of whom died during operation. Of the patients available for follow-up, 13 died within 8 years after the operation, and 13 are still alive, with varying survival periods up to 17 years. Operation by the Torkildsen procedure was performed on 11 patients, 5 of whom were operative fatalities. The authors believe that the procedure of fluid removal, followed by irradiation therapy for the treatment of tumors in the posterior portion of the third ventricle, is preferable to the direct surgical attack in view of the same comparative results and less degree of operative mortality.

Pulmonary Function Changes in Bilateral Resection for Pulmonary Tuberculosis. R. C. Young, F. J. Misener, J. J. Quinlan and J. E. Hiltz. Am. Rev. Tuberc. 79:468-473 (April) 1959 [New York].

Twenty-nine patients who had had bilateral pulmonary resections of tuberculous lesions performed between 1955 and 1958 at the Nova Scotia Sanatorium in Kentville were selected for study to determine the degree of change in pulmonary function after the operation. There were 16 males and 13 females, ranging in age from 10 to 49 years. Nineteen patients had moderately advanced tuberculous disease at the time of hospitalization. The ventilation tests included the determination of minute resting ventilation, expiratory reserve volume, vital capacity, and maximal breathing capacity. These tests were performed on all but a few patients less than 3 months before the first operation and between 3 to 6 months after each of the 2 resections. The results of the ventilation tests and the clinical evaluation of this study indicate that bilateral resection of reasonable extent affects the pulmonary function to a relatively mild degree. The vital capacity was appreciably more reduced in the major resection group (21%) than in the 2 minor, less extensive resection groups (14%), and the average reduction in vital capacity for all the patients was 18%. The changes in maximal breathing capacity correlated better with the extent of resection than did those of vital capacity and showed reductions of around 17% in the major resection group in contrast to no reductions in the minor resection groups. The average reduction in maximal breathing capacity in all the patients was 5%.

The probable principal cause for reduction in vital capacity is considered to be the restrictive effect of thoracotomy. In the more extensive resection the pulmonary factors undoubtedly influenced the results, but the maximal breathing capacity was apparently unaffected by the thoracotomy factor when the tests were performed several weeks after resection. Although the tests for maximal breathing capacity are valuable, they are not infallible because of the potential sources of error connected with their performance. No correlation could be found between other factors, such as the patient's age, preexisting condition, and type of disease, and the findings in the 3 groups undergoing resection.

The So-called Tight Filum Terminale Syndrome. A. Uihlein. Minnesota Med. 42:394-398 (April) 1959 [St. Paul].

The author reports on 2 women, aged 33 and 34 years, respectively, who on their admission to the Mayo Clinic presented the symptoms of an unexplained progressive paraparesis of the lower extremities suggesting the possibility of a tight filum terminale. The filum represents the caudad portion of the spinal cord which normally becomes a fibrous strand. Inadequate differentiation of the filum during the period of body growth, with lengthening of the filum as the vertebral column descends, can exert sufficient traction on the roots of the cauda equina and the conus medullaris to produce a demonstrable neurological disorder.

In addition to weakness and heaviness of the lower extremities, the first patient had urinary and fecal incontinence. Neurological examination revealed a definite sensory loss to all modalities in the sacral rootlets, with reduced sensitivity to touch, pain, and temperature. Surgical exploration in the region of the first lumbar vertebra revealed that the conus medullaris was not located at its usual level. Laminectomy at the fifth lumbar and first sacral levels revealed that the conus medullaris was attached to the dura at the level of the first sacral vertebra. The conus medullaris had undergone degenerative changes and looked somewhat like a lipoma. Anterior to this attenuated conus was a tense fibrous band that resembled the usual filum terminale. In the course of the intervention the attachment of the conus to the dura was divided between silk sutures, and then the tight filum was likewise divided. The tissue from the area of the conus was submitted to microscopic examination and represented fatty cells and nerve fibrils. Although much of the neurological deficit will persist, a satisfactory recovery is anticipated for this patient.

The right foot of the second patient was larger than the left, and the left foot was deformed, with a talipes cavus type of alteration. Neurological examination revealed that ankle jerks were absent bilaterally. The tone of the anal sphincters was reduced, and there was definite weakness in dorsiflexion of the toes, especially on the left side. There was weakness in the abductors and sensory loss to pinprick and temperature. An iophendylate (Pantopaque) myelogram showed the common dural sac lying posteriorly against the bony wall of the spinal canal, suggesting a tight filum terminale. Surgical exploration at the level of the fifth lumbar and first sacral vertebrae and at the level of the first and second lumbar vertebrae did not reveal any evidence of a tight filum terminale. The conus medullaris appeared to be in a normal position. Convalescence of the patient was uneventful. It was felt that she probably had a congenital anomaly of the lower extremity on the left side.

It is believed that in young patients with progressive paraparesis without adequate explanation for the findings early surgical intervention might prevent irreparable progressive neurological changes by determining the presence or absence of an abnormally low-lying conus medullaris of the spinal cord or a tight filum terminale or both. Roentgenograms of the thoracic and lumbar vertebrae, as well as contrast myelography, should be included among the measures employed in this clinical problem.

Sarcomas of the Stomach. M. Oria. Minerva chir. 14:229-235 (Feb. 28) 1959 (In Italian) [Turin, Italy].

Among 328 operations for benign or malignant tumor of the stomach performed at the Main Hospital in Turin during the past 10 years, 6 were concerned with sarcoma of the stomach in patients whose ages ranged from 57 to 68 years except for one whose age was 27. There were 3 instances of reticulosarcoma, 1 of fibrosarcoma, 1 of fibromyxosarcoma, and 1 of lymphoreticulosarcoma. The tumor, not being an extensively infiltrative type in these patients, was endogastric in 4, intramural in 1, and intramural with tendency toward the esogastric area in 1. Cramp-like epigastric pain was the initial symptom in 3 patients, and ulcer-like symptoms in the others. The symptoms developed within 2 to 8 months in 4 patients and within 1 to 2 years in the other 2 before hospitalization. The course of the disease became acute after onset of the symptoms, which circumstance brought the patients relatively early to the physicians' attention. Another salient feature was the absence of a true pyloric stenosis, although the considerable size of the tumors impeded the passage of food. Prognosis seemed to be more favorable in the patients with sarcoma than in those with carcinoma of the stomach because of a better indication for surgery, less tendency to metastatize, and possibility of an earlier diagnosis and referral to surgery. One patient died a year after the operation; 2 patients were alive 2 and 3 years, respectively, after the operation; 1 was operated on very recently; and 2 could not be traced.

An early and extensive operation is indicated for treatment of sarcoma of the stomach. Patients with inoperable disease are given irradiation therapy. Lymphosarcoma is more sensitive to roentgenotherapy than reticulosarcoma; fibrosarcoma is hardly sensitive to roentgenotherapy. Preoperative differential diagnosis of sarcoma of the stomach from carcinoma of the stomach is difficult, but it is possible with the aid of clinical, roentgenologic, and endoscopic findings.

Experimental Investigations on Induced Cardiac Arrest. A. Piskorz, J. Zawilski, I. Bowbelska and S. Drozdowski. Thoraxchirurgie 6:384-389 (March) 1959 (In German) [Stuttgart, Germany].

The authors describe animal experiments on induced cardiac arrest, which aimed at comparing the toxic effects of potassium ions and of acetylcholine, because either potassium citrate or acetylcholine are generally used for the induction of cardiac arrest in bypass operations on the heart. A de Wall-Lillehei oxygenator was incorporated in the apparatus which the authors used for the artificial maintenance of the circulation. Cardiac arrest was induced in 10 dogs by the injection of acetylcholine into the coronary vessels. This resulted in a sudden transition of normal cardiac function to arrest during the diastole. Only slight rhythmical atrial contractions could be observed, and occasional ventricular contractions resulted on touching the myocardium. The return of the cardiac function took place by way of occasional contractions which gradually merged into a normal sinus rhythm.

Potassium citrate was used to induce cardiac arrest in 13 dogs. The cardiac arrest was preceded in these dogs by irregular atrial and ventricular contractions. After arrest had been achieved, the relaxation of the myocardium was complete. The return of the cardiac function passed through a phase of irregular contractions, and in 5 animals cardiac massage had to be employed in order to restore the cardiac function. In 6 of the 13 dogs fibrillar, convulsive contractions resulted, which subsided spontaneously in only 1 dog; in the other 5 dogs, another injection of potassium citrate became necessary, but fibrillation recurred in 4 of the animals and resulted in their death on the operating table.

The authors conclude that, with the use of acetylcholine, cardiac arrest can be induced during the diastole for a period of from 10 to 20 minutes without noticeable impairment of the function of the heart muscle. The transition from normal sinus rhythm to cardiac arrest in the diastole takes place almost instantaneously, and normal heart action returns with full, although at first isolated, contractions which merge into a normal sinus rhythm. Acetylcholine does not achieve complete cardiac arrest; minor atrial contractions persist, and touching the heart elicits some complete contractions. Potassium citrate achieves a more complete cardiac arrest and relaxation of the myocardium than does acetylcholine, but the potassium ions involve the danger of inducing fibrillations, which may be fatal.

The Carcinoid Neoplasm and Syndrome: A Review with Extension by Unusual Cases. L. Gonzales, D. L. Graller, J. Giuseffi and A. M. Keirle. Am. Surgeon 25:226-231 (April) 1959 [Baltimore].

The authors report 2 unusual cases of carcinoid neoplasm and syndrome in a 47-year-old man and in a 12-year-old girl who were admitted to the surgical clinic of the University of Cincinnati Medical Center. The male patient was admitted because of nausea, vomiting, and diarrhea of 6 days' duration. Weakness 2 days before admission had forced him to bed. In the last 3 years he had had similar attacks, which were accompanied by flushing of the face, shoulders, and chest. The patient had undergone a laparotomy 2 years previously in another hospital for a suspected cholecystitis, and numerous tumor nodules had been found in the liver and 2 in the omentum. No primary source of the tumor had been found in the intestine. A liver biopsy had been reported as revealing metastatic carcinoma. On the present admission, a chest roentgenogram revealed a rounded nodule in the midlung field, which was thought to represent a neoplastic lesion, with probable sclerosing lesions of the ribs. An abdominal roentgenogram revealed extensive hepatomegaly and sclerosing lesions of both the ilia and the sacroiliac joints and of the 8th, 9th, and 12th thoracic vertebrae. The urine test was strongly positive for 5-hydroxyindole acetic acid (serotonin). The patient's symptoms, characteristic flush, and 2-year history of surprising work activity after the detection of a metastatic tumor in the liver supported the diagnosis of metastatic carcinoid. A bone biopsy of the posterior iliac spine on the right revealed carcinoid tumor. The roentgenogram showing osteoblastic bone metastases was disconcerting, as osteoblastic metastases are extremely rare. The similarity of the bone biopsy to the liver biopsy taken 2 years previously and the high urinary serotonin content established the diagnosis.

The 12-year-old girl was studied for obesity. On examination an intense mottled redness of the face was seen. In the last 4 years she too had had occasional attacks of vomiting and diarrhea. The increasing awareness of the sarcoid syndrome and the patient's positive reaction to the serotonin test established the diagnosis of carcinoid neoplasm, and an exploratory laparotomy was performed. The liver was found to be tremendously enlarged, with tumor nodules. At the junction of the jejunum and ileum a stenosing lesion of the ileum was found, extending for a distance of 2 cm. and involving two-thirds of the circumference of the intestine. There was extension of this tumor into the root of the mesentery. A wedge resection of the area and biopsy of the liver were performed. Microscopic examination of the specimens revealed carcinoid of the ileum with metastases to the liver.

Forty-eight additional cases of carcinoid tumor were collected from the records of the University of Cincinnati Medical Center during the last 10 years. Eleven of these tumors were appendical in origin, 34 occurred in the small intestine, and 3 arose in the rectum. Thirty-one of the 34 tumors in the small intestine were located in the terminal ileum, 2 in the jejunum, and 1 in the duodenum. Thirteen of the 34 tumors were malignant; 9 of these were diagnosed at laparotomy and treated surgically. Follow-up of the 9 patients with these tumors showed only 2 survivors. The average survival time from the onset of symptoms was 8.2 years and from the time of diagnosis 3.5 years.

Gastrojejunal Ulcer. H. Jinich, J. Solis, A Pitol and J. Sierra F. Rev. invest. clín. 10:383-406 (Oct.-Dec.) 1958 (In Spanish) [Mexico, D. F.].

The records of 33 patients with gastrojejunal ulcer, secondary to a previous operation for peptic ulcer, who were treated at the Hospital de Enfermedades de la Nutrición in Mexico City, were reviewed. There were 27 men and 6 women who ranged in age from 30 to 60 years. The previous operation had been performed for a duodenal ulcer in 31 patients and for a gastric ulcer in 2. It consisted of gastroenteroanastomosis, alone or with vagotomy, in 16 cases and of gastric resection ("insufficient" or "ample") in the other 17. The symptoms of recurrent ulcer appeared during the immediate postoperative period in 5 patients and within an average period of 2 years in the remaining 28. The most characteristic symptom of recurrent ulcer was epigastric pain similar to that which occurred before the previous operation. Early symptoms of this recurrence gave rise later to chronic or acute perforation in 28 cases, severe hemorrhage in 12, gastric retention in 10, gastrojejunocolic fistula in 2, and malnutrition in 16.

The clinical diagnosis was confirmed by determination of gastric acidity, gastroscopy, and radiologic examination of the stomach. There was gastric hyperacidity in 25 of the 30 patients who had this examination and hypoacidity in 5. Gastroscopy showed superficial gastric lesions. Radiologic examination proved to be of value in the detection of gastrojejunal ulcer and of its complications, the radiologic sign being the crater or "niche." The radiologic picture of gastric retention due to gastrojejunal ulcer or gastrojejunocolic fistula was extremely clear. Twelve patients who did not respond to medical treatment disappeared from observation, but 19 patients had a second operation, consisting of gastric resection, alone or with vagotomy, or vagotomy, alone or with closure of the perforation and undoing of the original stoma. Ample gastric resection (Hofmeister's operation) was performed on 12 patients; 2 patients died in the immediate postoperative period (constituting 16% mortality).

Vagotomy, alone or with closure of the perforation, was performed on 6 patients, and there was no operative mortality.

The authors conclude that gastric resection, alone or with resection of the ulcerous jejunal segment, is indicated in surgical treatment of postoperative peptic ulcers; these ulcers develop in patients in whom the first operation has been a gastroenteroanastomosis, an insufficient gastrectomy, or an ample gastrectomy, which left a functionally defective anastomosis. Vagotomy is indicated in cases of gastrojejunal ulcer, secondary to ample gastric resection or to gastroenteroanastomosis, if the anastomosis functions well.

Ectopic Breast Tissue: Report of Unusual Case. C. M. Looney, S. C. Reichman and O. F. Noel. Am. Surgeon 25:219-222 (April) 1959 [Baltimore].

The authors report a 26-year-old pregnant woman with hypertrophied breasts, who was admitted to the surgical clinic of the Vanderbilt University Hospital in Nashville, Tenn., for treatment. No secretion could be expressed from the nipples, and the right breast was larger than the left. Just superior to the right nipple there was an area of erythema with tenderness and an orange-peel appearance. The vulva was normal on pelvic examination. After an unsuccessful attempt was made to aspirate the mass in the right breast, a biopsy was performed 8 days later on this mass. Microscopic examination revealed mastitis without evidence of carcinoma.

About 6 weeks later the patient returned to the Vanderbilt Hospital and stated that one month before she had noticed a small mass in the medial inferior portion of the right breast; this mass had increased in size and the night before coming to the clinic had begun to drain. On examination, the right breast was somewhat larger than the left, and both were warm and showed the orange-peel phenomenon. A mass, 2.5 cm. by 2.5 cm., was noted in the medial inferior quadrant of the right breast. There was an ulcerated area draining a clear, watery fluid. No axillary lymphadenopathy was present. Pelvic examination revealed a uterus the size of 3 months' gestation. The appearance of the vulva was not mentioned. A bilateral simple mastectomy was done. The total weight of both breasts was 28 lb. 13 oz. (13 kg.). The patient's hospital course was uneventful, and 6 months after the operation she was delivered of a normal male infant.

One year later the patient was admitted to the Nashville General Hospital. Physical examination revealed a pregnant uterus of about 8 months' gestation and bilateral vulvar masses which were of such size that it was felt they would obstruct the vaginal outlet at the time of delivery. The 2 vulvar masses were excised; on gross examination they had the appearance of breast tissue, and microscopic examination revealed well-circumscribed lobules of highly secretory breast tissue. A week later the patient was delivered of a normal male infant.

Ectopic breast tissue may occur at any location along the milk line extending from the axilla to the medial surface of the upper thigh. The incidence of occurrence is from 1 to 2%, and such tissue may be either unilateral or bilateral. Due to the rare occurrence of malignant change, these masses give the impression of being relatively harmless. When malignant changes do occur, the prognosis is poor because of the proximity of regional lymphatics. Breast tissue occurring in the vulva unilaterally, though reportedly rare, is not too uncommon. A careful review of the literature revealed only 3 reported cases in which breast tissue was found in the vulva bilaterally. The 4th such case is reported by the authors.

Lipid Mobilization as a Consequence of Surgical Stress. C. J. D. Zarafonetis, J. Seifter, D. Baeder and J. P. Kalas. Am. J. M. Sc. 237:418-433 (April) 1959 [Philadelphia].

The effect of surgical stress on the plasma concentration of lipid mobilizer hormone and on the plasma lipids was investigated in 26 patients during the course of various operative procedures at the Temple University Hospital in Philadelphia. Lipid mobilizer hormone assays, cholesterol and fatty acid determinations, and paper electrophoretic patterns of lipoproteins were made on blood specimens obtained from the antecubital vein before and 4 hours after the operation. Similar tests were performed on samples taken from the omental artery and the omental vein at the beginning and at the end of intra-abdominal procedures. The most important findings and their implications may be listed as follows: 1. Evidence was obtained that lipid mobilizer hormone is released during surgical stress. 2. This release leads to mobilization of triglycerides from the omental depot. 3. There is a marked shift in paper electrophorograms from alpha-lipoprotein to beta-lipoprotein predominance in the omental vein blood during surgery. 4. The omentum not only responds actively to endogenous lipid mobilizing hormone with an outpouring of the aforementioned lipid components, but also appears to remove cholesterol from the blood circulating through it. 5. The lipid changes which may occur in the peripheral blood during surgical stress reflect the foregoing events as well as the capability of the liver to metabolize the lipids presented to it. The authors believe that these observations, made on patients undergoing the stress of surgery, permit delineation of a physiological mechanism in man for the acute mobilization of lipids to the liver.

Surgical Treatment of Cardiospasm. E. Hasche and H. Schubert. Thoraxchirurgie 6:434-457 (March) 1959 (In German) [Stuttgart, Germany].

The clinical picture of cardiospasm has been described under such terms as "achalasia or dystonia of the esophagus" and "dilatation of the cardial portion of the esophagus." This functional obstruction of the cardia has been ascribed to incoordination of the opening reflex of the cardial portion of the esophagus, which, in turn, has been ascribed to degeneration of the ganglion cells of Auerbach's plexus. The authors report their observations on 50 patients with cardiospasm observed at the surgical university clinic of the Charité in Berlin during the last decade. A psychological component played a significant part in the production or the exacerbation of many cases of cardiospasm during the difficult after-war period. A psychological trauma could be established as the eliciting factor in 16% of the patients. The diagnosis often proved difficult. A megaesophagus was sometimes mistaken for a mediastinal tumor, and in young persons bronchiectasis was sometimes suspected. The fact that cardiospasm may accompany esophageal or ventricular fundus carcinoma constitutes another difficult factor in diagnosis.

Treatment should always begin with conservative measures. Psychotherapy and removal from conflict situations proved helpful in all 6 patients in whom these measures were tried. Medicinal therapy and dietetic measures were effective in 14 of 16 patients. Nonsurgical dilation or spreading of the cardia by means of dilating sounds was tried in 16 patients. It was effective in 7, ineffective in 5, and caused complications in 4. Three of these 16 patients died of suppurating mediastinitis brought on by instrumental perforation of the cardia.

The main portion of the paper is concerned with the surgical treatment of cardiospasm, which was employed in 12 of the 50 patients. In all except one the cardiospasm had existed for many years (5 to 37). Myotomy was performed on 4 patients, anastomosis on 4, and resection on 4. The late results are analyzed. On the basis of clinical, roentgenologic, and esophagoscopic follow-up examinations, the authors discuss the sequels that result from esophagogastrostomy and resection of the cardia, particularly reflux esophagitis and cicatricial stenosis. Cardiomyotomy according to Gottstein-Heller proved to be the best surgical method. This operation is technically simple and relatively safe, and it preserves the physiological conditions. It does not destroy the valve and closure mechanism between esophagus and stomach, and as a result it is not complicated by gastroesophageal reflux with its serious sequels. These favorable results of cardiomyotomy were corroborated by a review of the literature, in that it demonstrated successful results in 90% of about 800 cases.

Cancer of Pancreas: Symptomatology and Therapy. H. Prydz. Tidsskr. norske laegefor. 79:252-256 (March 1) 1959 (In Norwegian) [Oslo].

Forty-two patients, 28 men and 14 women, aged from 34 to 77 years, with cancer of the pancreas and cancer of the duodenal papilla, were treated in the Drammen (Norway) Hospital from 1946 to 1958. Laparotomy was performed in 28 cases. About two-thirds of the cases were localized to the head of the pancreas. Differentiation between cancer of the head of the pancreas and cancer of the duodenal papilla is often possible only on microscopic examination. The extent of the cancer may be difficult to evaluate because of secondary pancreatitis. Besides the rare sarcoma, malignant tumors in the pancreas include adenocarcinoma, cystadenocarcinoma, and islet-cell tumor. Adenocarcinoma is frequent and is the most malignant. In the 22 cases examined histologically, the diagnosis was adenocarcinoma; in 4 cases the cancer developed from the duodenal papilla. In 16 cases the symptoms were gastrointestinal; in 11 there were symptoms from the liver and biliary tract; and in the remaining cases there were various other pancreatic symptoms. The frequency of affection of the biliary tract is ascribed in part to secondary changes due to obstruction of passage by the tumor. The possibility of early diagnosis is still slight. Courvoisier's law is of little help in practical diagnosis. A positive roentgen-ray finding is a strong indication that the tumor cannot be operated on radically. Exploratory laparotomy showed 10 patients to be unfit for formation of an anastomosis. In 14 cases palliative anastomosis was formed between the biliary tract and the intestine, and in 14 cases Whipple's operation was performed. Of the 14 patients operated on by Whipple's method, 8 died postoperatively, with the picture of shock, hepatic coma, and hyperpyrexia. The results were somewhat better in the palliative anastomosis operation—2 out of 14 patients died postoperatively.

NEUROLOGY & PSYCHIATRY

Facial Paralysis in Poliomyelitis: Report of 3 Patients with Unusual Delayed Paralysis. I. C. Sherman and S. J. Kimelblot. Neurology 9:282-287 (April) 1959 [Minneapolis].

The records of all patients diagnosed as having poliomyelitis at Michael Reese Hospital, Chicago, during 1952-1956 were reviewed. Of 407 patients with poliomyelitis, 267 had some form of paralysis. Of these, 203 patients had paralysis involving only spinal musculature; in 64, musculature supplied from the brain stem was involved. Of the 64 patients with bulbar involvement, 34 had some type of facial involvement. Thus, approximately 50% of patients with bulbar involvement had facial paralysis, while, of all 267 patients with paralysis, the face was involved in 12.7%. The incidence of facial paralysis in all 407 patients diagnosed as having poliomyelitis was 8.3%. A tabulation of cases according to years revealed great variation in the incidence of bulbar cases in any one year, even though the proportion of paralytic to nonparalytic cases did not vary widely. Facial paralysis was the only sign of bulbar involvement in 4 patients, although these individuals also had evidence of spinal cord involvement. Only 1 of the 34 patients with facial paralysis could be said to have an isolated facial paralysis in that he had no other evidence of bulbar or spinal involvement.

Facial paralysis in poliomyelitis nearly always appeared within one day of the appearance of paralysis in the bulb or elsewhere. Descriptions were given of 3 patients in whom unusual delay in appearance of facial paralysis occurred. One was a woman with bulbospinal disease in whom bilateral facial paralysis developed 11 days after the palatal weakness appeared and 6 days after she had become afebrile. At that time, she still had 18 cells per cubic millimeter and 138 mg. of protein per 100 cc. in her spinal fluid. The second patient was a man in whom a left-sided facial paralysis developed 10 days after the appearance of weakness of the left side of the palate, vocal cord, and pharynx, and 1 day after he had become afebrile. His spinal fluid was normal at this time. The third patient was a young man who had right-sided palatal weakness and 10 days later (3 days after becoming afebrile) paralysis of the left side of his face. At this time he had 25 cells per cubic millimeter in his spinal fluid. All 3 of these patients recovered completely from signs of palatal, pharyngeal, and facial weakness.

Imipramine (Tofranil): A New Drug for the Depressed. H. Azima. Canad. M. A. J. 80:535-540 (April 1) 1959 [Toronto].

A new drug, imipramine (Tofranil), was given a trial in 100 consecutive patients manifesting symptoms of depression and seen either as outpatients or in an open psychiatric setting at the Allan Memorial Institute in Montreal. There were 30 men and 70 women, with an average age of 49 years. Of the 100 patients, 38 were neurotics, 6 were hypochondriacs, 8 had mixed states including anxiety, depression, hysterical and obsessive compulsive features, 4 were alcoholics with depression, and 44 had psychotic depressive states. Imipramine was administered orally to all the patients. The average effective dose was 100 mg. daily; the optimal initial dose was 75 mg. daily, which was increased to 150 mg. within 7 days if no cumbersome side-effects were apparent. Usually it was not necessary to give more than 200 mg. daily. The drug was given for an average initial period of 20 days, and its administration was discontinued if no response was elicited within this period. The follow-up period ranged from 3 to 9 months. In general, 82 of the 100 depressed patients showed improvement, which was marked in 44 and moderate in 38. Patients with psychotic depression showed twice as much improvement as those with neurotic depression. All the patients with psychotic depression and most of those with neurotic depression would have required electroshock therapy if imipramine had not been used.

There was a therapeutic lag of 2 to 30 days between the institution of imipramine therapy and the onset of therapeutic response. The impression was that maintenance therapy should be continued for about 3 months after the appearance of an appreciable amount of improvement. Side-effects, such as tremor, agitation, nausea, vomiting, dizziness, and perspiration, were of minor consequence. The mode of action of imipramine was interpreted as a shift in aggressive cathecting energies of internalized object systems of control (supergo component), with a secondary reorganization of libidinal investment. The general impression was that imipramine proved to be a potent antidepressant substance, which already had resulted in a drastic decrease in the number of sessions of electroshock treatment.

The Use of Imipramine (Tofranil) for Depressive States in Open Ward Settings of a General Hospital: A Preliminary Report. R. B. Sloane, A. Habib and U. E. Batt. Canad. M. A. J. 80:540-546 (April 1) 1959 [Toronto].

Imipramine (Tofranil) was given to 8 men and 22 women, between the ages of 33 and 85 years, with symptoms of depression, most of whom had manic-depressive depressed psychosis requiring hospitalization. These 30 patients were admitted to wards of the Kingston (Ont.) General Hospital. The depression in most of these patients was characterized by subjective feelings of fatigue, weakness, slowing down, sadness, and guilt, accompanied by a loss of appetite and sleeplessness. The clinical picture ranged from severe retardation and near stupor, at one extreme, to severe agitation, at the other, through the usual intervening stages. In some patients the covert depression took the form of extreme hypochondriasis. The criterion of selection was a severity of symptoms justifying the use of electroshock therapy. Imipramine was usually given by mouth in doses of 50 mg. 4 times daily, and this remained the average dose for all patients. The upper limit of dosage was 600 mg. in one day.

Of the 30 patients, 4 recovered, 12 were much improved, 9 were improved, and 5 were unchanged; 25 patients (80%) thus obtained satisfactory results, and the mean hospital stay was 5 weeks. These results were comparable to, if not somewhat better than, those from electroshock therapy. The results of a double-blind controlled study carried out on 12 patients, 6 of whom received imipramine and 6 a placebo, showed that it was impossible to distinguish between placebo and active compound for the first 2 weeks after admission to hospital. Similarly, the improvement produced by the active drug was no better than that caused by the placebo during this time. These results suggest perhaps underestimating the value of hospital admission per se in gratifying the needs of patients with depression. Such studies need to be extended. Follow-up of the patients for 4 months after their discharge from the hospital showed that administration of imipramine probably has to be continued over a considerable period of time and remission may follow withdrawal of the drug. It is concluded that imipramine is a useful drug in the treatment of depression; further work may clarify its best usage.

Hyperinsulinism: Rare Cause of Epilepsy. D. W. Mulder and J. G. Rushton. Neurology 9:288-289 (April) 1959 [Minneapolis].

The authors direct attention to an earlier report in which Breidahl and associates reported that the condition of patients with functioning adenoma of the islet cells of the pancreas is frequently diagnosed as epileptic. Of 91 patients seen at the Mayo Clinic, 37 had what are called convulsive seizures as a clinical symptom. The recognition of seizures secondary to hyperinsulinism is of clinical importance, as hyperinsulinism due to a pancreatic adenoma may be cured surgically. Because of the frequent confusion in diagnosis between hyperinsulinism and epilepsy, some investigators have suggested that every patient with seizures should have a fasting blood sugar determination. In the experience of the authors routine determination of fasting blood sugar has not proved to be an effective aid in the recognition of hyperinsulinism.

In order to differentiate epilepsy due to hyperinsulinism from epilepsy due to other causes, the authors reviewed the records of 91 patients with hyperinsulinism previously described by Breidahl and associates. The term "hyperinsulinism" is reserved for patients in whom a hyperfunctioning tumor of the islets of Langerhans has been found. An epileptic seizure is defined as "a brief, abrupt, recurrent, paroxysmal, stereotyped cerebral storm inappropriate to the immediate situation and followed by transient impairment of cerebral function." Transient recurrent cerebral symptoms and signs were common in the 91 patients. The criteria just mentioned for recognition of an epileptic seizure were applied to these symptoms.

In 21 of the 37 patients in whom Breidahl and associates had observed convulsive seizures, the recurrent cerebral symptoms were gradual in onset, variable in manifestations, and of long (several hours to days) duration. The character of these attacks was distinctly different from an epileptic seizure. The authors, therefore, conclude that only 16 of the 91 patients had had epileptic seizures. Fifteen of the 16 patients had seizures best classified as generalized convulsions. In some the attack was typically grand mal, while in others loss of consciousness occurred with only mild tonic or clonic movements. In 9 patients prodromal symptoms of paresthesia, dazed feeling, sweating, pallor, faintness, hunger, or diplopia occurred, usually 30 minutes or more before onset of a convulsion. In 14 of 16 patients the first seizure occurred between the ages of 31 and 63 years. In 2 the first seizure occurred at ages 9 and 23 years respectively. Frequency of these seizures varied greatly. In 8 patients attacks occurred several times a week to several times a month, but the others had had only a few or single seizures.

Neurological examination and electroencephalographic study, conducted at a time when the patient did not have hypoglycemia, usually produced normal results. One patient had a positive Babinski sign and an abnormal increase in the activity of muscle stretch reflexes on the left side. In only 3 patients were electroencephalographic abnormalities noted: slight dysrhythmia in 2 and bitemporal slow waves in 1. In these 16 patients with epilepsy, the cause of hyperinsulinism was adenoma of the islet cells of the pancreas in 9 and adenocarcinoma in 7. The authors could discover no relationship between the type of pancreatic lesions and the character or frequency of the epileptic seizures.

Late Prognosis of Chlorpromazine Jaundice. A. G. Melrose and J. R. Roy. Brit. M. J. 1:818-819 (March 28) 1959 [London].

Jaundice, the best known of the complications of chlorpromazine therapy, has an incidence of about 1%. The authors cite one investigator who found that, in 55 patients hospitalized with jaundice in 1957, chlorpromazine was the cause in 5. It is believed that jaundice is caused by hypersensitivity to the drug within the liver, which may result in an increased permeability of the cholangioles. The characteristic histological picture is one of biliary stasis, with infiltration of the portal tracts by polymorphonuclear leukocytes, among which eosinophils are frequent. In most patients the period of jaundice is brief, lasting only a few weeks, but in some jaundice has been known to persist for months.

In order to ascertain whether disappearance of the jaundice is followed by complete histological and functional restoration, the authors made studies on 2 patients, a 52-year-old woman and a 48-year-old man, who had had chlorpromazine jaundice 6 months and 1 year previously. They were studied by means of liver-function tests and needle biopsy.

Neither had suffered previously from liver disorder, and no clinical stigmas of chronic liver disease were noted while they were under observation. Persistent histological changes were observed in both patients, but biliary cirrhosis was not observed. In one patient the liver function tests remained abnormal.

Chlorpromazine is of such recent introduction that enough time has not yet elapsed for the ultimate prognosis in all patients who develop jaundice to become clear. The present investigation indicates that restoration of normal liver histology or function, or both, may be long delayed. If permanent changes were to ensue, the original cholangiolytic type of lesion is of a nature that could lead to biliary cirrhosis. Literature reports are cited confirming this possibility. The authors conclude that, since the drug is potentially toxic, it should not be used without careful consideration.

PEDIATRICS

Chronic Idiopathic Hypercalcemia (Fanconi-Schlesinger Type): Treatment with Thyroxin. C. Hooft and A. Vermassen. Maandschr. kindergeneesk. 27:37-52 (Feb.) 1959 (In Dutch) [Leiden, Netherlands].

The female infant whose history is presented was born to normal parents, although the father's family included members with some defects, particularly low stature. The mother's pregnancy and delivery were normal. It was not known whether the mother had received supplementary vitamin D during her pregnancy. The infant exhibited anorexia, vomiting, and failure to thrive from birth, also constipation, retardation of both physical and mental development, marked hypotonia, a characteristic facies, small head, hypertension, and a heart murmur. The most important biochemical findings were persistent hypercalcemia, hypercholesterolemia, and subnormal renal clearances. Roentgenoscopy revealed dense transverse bands in the metaphyses of the long bones and increased density at the base of the skull. The first clinical features—anorexia, vomiting, and failure to grow normally—were definitely present before vitamin D was administered or vitaminized milk was given. The existence of increased sensitivity to vitamin D was established later.

The authors point out that hypercalcemia can develop in children not only after the administration of excessive doses of vitamin D but also in connection with certain disorders, such as hyperparathyroidism, sarcoidosis, interstitial plasma-cell pneumonia, hypophosphatasia, prolonged immobilization, and hypothyroidism, and with malignant conditions, such as leukemia, Hodgkin's disease, or sympathicoblastoma. Frequently children with these disorders are more sensitive to vitamin D than normal children. In recent years hypercalcemia without apparent cause has also been reported in the absence of the aforementioned disorders. "Idiopathic hypercalcemia in infants with failure to thrive" was described by Lightwood and Payne in Britain in 1952, and during the same year Fanconi and associates in Switzerland and Schlesinger and others in Britain described "chronic hypercalcemia, combined with osteosclerosis, hyperazotemia, subnormal growth, and malformations." It is suggested that the disorder described by Lightwood is a mild or incomplete form of the syndrome described by Fanconi and Schlesinger. The benign or incomplete form is usually reversible within a few months. The more severe form begins earlier in life, the hypercalcemia is more persistent, severe physical and mental defects exist, and death may result from renal damage or intercurrent diseases.

With regard to the case presented, the authors suggest that this type (Fanconi-Schlesinger) of idiopathic hypercalcemia results from a metabolic abnormality of endogenous vitamin-D-active substances, probably sterols. Treatment with thyroxin was followed by improvement in all the clinical, biochemical, and roentgenologic features. This favorable effect of thyroxin could not be explained by a clinically observable hypofunction of the thyroid, but it presumably resulted from the increased excretion of calcium both in the urine and in the feces. It is possible that thyroxin has a direct effect on the vitamin D activity in the serum.

A Controlled Study of Three Methods of Prophylaxis Against Streptococcal Infection in a Population of Rheumatic Children: II. Results of the First Three Years of the Study, Including Methods for Evaluating the Maintenance of Oral Prophylaxis. A. R. Feinstein, H. F. Word, J. A. Epstein and others. New England J. Med. 260:697-702 (April 2) 1959 [Boston].

Three hundred ninety-one children and adolescents, with unequivocal previous attacks of rheumatic fever, were followed at the Irvington House Prophylaxis Clinic, New York, in a special study designed to compare the effectiveness of 3 prophylactic regimens in the prevention of streptococcic infections and rheumatic recurrences. At the start of this study, a statistical method of random selection was used to divide the patients into 3 groups comparable in age, cardiac status, and duration of freedom from rheumatic activity. Each group was assigned to 1 of the 3 therapeutic agents under study: 1 Gm. of sulfadiazine given daily by mouth; 200,000 units of potassium penicillin G given daily by mouth; and injections of 1,200,000 units of benzathine penicillin G per month. The patients were examined monthly after the beginning of the study. Streptococcic infections were detected by careful bacteriological and immunological techniques (with the use of antistreptokinase and antihyaluronidase as well as antistreptolysin-O titers when necessary). Recurrences of rheumatic fever were diagnosed by means of the modified Jones criteria.

The data for the first 3 years of this study have now been completed and show the following incidence of streptococcic infections per patient year in each group: sulfadiazine, 21.1%; penicillin given by mouth, 20.7%; and penicillin given by injection, 7.3%. When the group of patients taking the drugs by mouth was divided into those who maintained good prophylaxis and those who did not, it was found that the injections were still more effective than either preparation given orally for the prevention of streptococcic infections, and that sulfadiazine had been more effective than penicillin given by mouth to patients who maintained good prophylaxis. The recurrence rate of rheumatic fever per patient year was as follows: sulfadiazine, 1.9%; penicillin tablets, 5%; and penicillin injections, 0.3%.

These data show unequivocally that injections are more effective than oral administration of either sulfadiazine or penicillin, in the dosage schedule used, for the prevention of streptococcic infections and rheumatic fever. Of the 2 agents given orally, sulfadiazine has been as good as, and possibly superior to, penicillin. This observation has many ramifications for the mass-scale rheumatic-fever prophylaxis programs now in operation. The apparent superiority of sulfadiazine is now being tested against a double dose of penicillin in a new group of patients who have been added to those in the original study.

Vasopressin-Resistant Diabetes Insipidus. S. A. Kaplan, A. M. Yuceoglu and J. Strauss. A. M. A. J. Dis. Child. 97:308-313 (March) 1959 [Chicago].

In 3 generations of a Negro family there were 8 members with vasopressin-resistant diabetes insipidus. Of the 8 patients, 4 were children (3 boys and 1 girl between the ages of 3 months and 4½ years), and 3 were adults (the mother of one of the boys and 2 of her sisters). The most remarkable feature of the disease as manifested by these patients was its extraordinary variability. Some of the patients had only polyuria and polydypsia, but in one patient there occurred, temporarily, growth retardation, hypernatremia, reduced urea clearance, and severe impairment of renal powers of base conservation. In 3 patients there was marked hyperaminoaciduria. Except for aminoaciduria and failure to concentrate maximally, renal function appeared to be normal in all the patients when this paper was written. It is worthy of note that in this family vasopressin-resistant diabetes insipidus occurred in both males and females. Reports on 120 patients with this disease were collected from the literature. The reported data support the contention that in many instances, at least, vasopressin-resistant diabetes insipidus is not transmitted by a sex-linked recessive gene but by an autosomal dominant.

THERAPEUTICS

Hemisulfur Mustard in the Palliation of Patients with Metastatic Ovarian Carcinoma. T. H. Green. Obst. & Gynec. 13:383-393 (April) 1959 [New York].

The author reports the experience accumulated between 1953 and 1958 at the Vincent Memorial Hospital in Boston in the use of hemisulfur mustard to achieve palliation and particularly control of ascites in 30 patients with disseminated ovarian carcinoma. All these patients had been given benefits of surgery and radiation therapy before the therapy with hemisulfur mustard. All of them were hospitalized during and for a few days after treatment with hemisulfur mustard. Pretreatment consisted of 0.1 Gm. of diphenylhydantoin (Dilantin) given orally 3 times daily for several days prior to the administration of hemisulfur mustard. Dilantin was continued during treatment and for several days thereafter and was given intramuscularly whenever nausea and vomiting intervened. Preparations with cerebral-stimulating effect should not be given during or immediately after hemisulfur mustard therapy. The standard course of intravenous therapy with hemisulfur mustard consisted of 3 divided doses of 200 mg. each, an interval of at least 48 hours being allowed between injections or until any signs of toxicity had subsided. It is necessary to make the injection into a large vein to avoid skin irritation and phlebitis. Occasionally the third and last injection was omitted because of the occurrence and persistence of significant symptoms of neurotoxicity. A single dosage of 300 to 350 mg. of hemisulfur mustard was used for direct intraperitoneal injection. The solution is prepared immediately before the intraperitoneal injection in exactly the same manner as for intravenous injection. Paracentesis was done with the usual small trocar, which removed about half of the ascitic fluid present.

Nineteen of the 30 patients were treated intravenously and 11 by direct intraperitoneal injection. Fifteen of the 19 patients treated intravenously and 6 of the 11 patients treated by direct intraperitoneal injection experienced significant benefit from the drug. The longest post-treatment survival to date has been 33 months among these patients; 8 patients lived, or are at present living, 6 to 12 months after treatment. Of the 9 patients who did not benefit from the drug, 3 survived for 3, 7, and 10 months, respectively, 4 died within 6 weeks of therapy, and 2 died during intravenous therapy; of the latter 2, one died of pulmonary embolism and the other in severe convulsions. Suppression of ascites was the most frequent favorable objective response, and there was complete and permanent disappearance of abdominal fluid in 62% of the patients, with significant decrease in the rate of formation in an additional 15%. In 8 patients a decrease in size of palpable abdominal or pelvic masses was observed. The intravenous administration of hemisulfur mustard seemed to produce favorable palliative effects in a somewhat greater percentage of patients than did the intraperitoneal instillations; but the single injection technique of direct intraperitoneal instillation offers many advantages to the patient in its ease and simplicity. Absence of toxic side-effects and shortened hospitalization time seem to warrant continued trial, particularly in patients who present only the problem of ascites in the absence of large masses or other manifestations of metastatic disease.

Potentiation of Biological Activities of Steroids by Carcinogenic Hydrocarbons. E. Myles Glenn, S. C. Lyster, B. J. Bowman and S. L. Richardson. Endocrinology 64:419-430 (March) 1959 [Springfield, Ill.].

Previous studies by other investigators had suggested that local implantation of certain carcinogenic hydrocarbons antagonizes or inhibits the biological response of specific target organs to androgens, estrogens, and progestational agents. It had been demonstrated that an experimental mammary fibroadenoma, refractory to steroid therapy alone, showed a marked retardation of growth when androstan-17β-ol-3-one and 3-methylcholanthrene were administered together. When administered alone, neither compound induced a marked degree of inhibition. These results led to a hypothesis that carcinogenic agents may alter the response of certain cells to steroid hormones and that systemic administration of carcinogenic hydrocarbons may produce different effects from those observed after local implantation. The experiments described here were designed to determine the influence of carcinogenic hydrocarbons on biological effects produced by androgens and adrenocortical steroids.

The authors demonstrated in experiments on rats that oral administration of 3-methylcholanthrene, 2-anthramine, benz-α-pyrene, and 7-methylbenzanthracene, all carcinogenic agents, greatly potentiated both the androgenic and the myotropic effects of 17-methyltestosterone. Noncarcinogenic hydrocarbons investigated were nearly inactive in this regard. Oral and direct administration of 3-methylcholanthrene potentiated both the glycogenic and the antiphlogistic properties of hydrocortisone. Inactive hydrocarbons, anthracene and phenanthrene, failed to induce this type of phenomenon. Both in vivo and in vitro studies indicated that the ability of carcinogenic hydrocarbons to potentiate biological effects of steroids is due to a direct effect of the carcinogenic agent at the cellular level and not to a decreased rate of steroid metabolism by the liver.

Glycine in Hypochromic Microcytic Anemia. A. Y. Kim, W. A. Beck, C. H. Kim and H. S. Portogallo. Northwest Med. 58:383-388 (March) 1959 [Seattle].

This report is based on observations made with Glytinic, a hematinic agent supplemented with glycine and containing ferrous gluconate, B vitamins, and trace elements, in the treatment of 60 patients with hypochromic microcytic anemia. There were 2 groups of patients, those who did not respond to the usual iron therapy and those who demonstrated an intolerance to iron therapy. Thirty of the patients who did not respond to iron therapy were patients in whom anemia developed as a result of long-standing low-protein intake. Twenty of these patients were given 100 mg. of iron as ferrous gluconate in a daily dose for 90 days and 10 were given 333 mg. of ferrous sulfate for 60 days daily, but no hematological response was noted. When Glytinic was administered, however, the hematological response was good. The remaining 30 patients who had demonstrated an intolerance to iron therapy or ferrous sulfate all responded well to the administration of the glycine-supplemented hematinic. Glycine was felt to be of value as an amino acid concerned with hemoglobin synthesis or as an expedient source of nitrogen for the production of other amino acids required for hemoglobin synthesis. Only 5 out of 656 patients who were tested over a 4-year period by the authors demonstrated mild gastrointestinal disturbance, which shows that a glycine-supplemented hematinic is well tolerated.

PATHOLOGY

Alcohol as a Factor in Medico-Legal Sudden Deaths. C. Duncan. M. J. Australia 1:322-323 (March 7) 1959 [Sydney].

It has been pointed out that, while it is illegal to take without consent blood from a live person for the purpose of alcohol estimation, there is no fear of a charge of assault when the blood is taken from the dead body at an autopsy. There are satisfactory methods for estimating the postmortem blood alcohol levels, and the results are reliable if the blood is taken from a peripheral source, but are open to errors if it is taken from the heart, the chest, or the abdominal cavities. The author says that in Hobart, Tasmania, the value of blood alcohol tests in connection with the coroner's work has been realized for a long time, but until fairly recently facilities for performing the estimations were lacking. Now they are carried out in the government analyst's department.

Whenever possible, blood is withdrawn by cutting through a femoral vein, and several milliliters can usually be obtained. Occasionally, in subjects with great blood loss, the femoral vessels are empty, and it is necessary to depend on the cerebral vessels. Urine also is collected, if the femoral vein site is unsatisfactory, or if there are unusual circumstances about the death. The blood or urine is delivered immediately to the analyst, who adds fluoride as a preservative if the test is not made until later. The analyst reports the alcohol content of the blood in milligrams per 100 ml. of blood, works out the total amount of absolute alcohol present in the body on the basis of the deceased's weight, and then gives the amount of whisky and beer which is equivalent to the calculated amount of alcohol present. The test is not used in all deaths but in murder, manslaughter, and some traffic accidents and in cases in which alcohol is suspected as a causative factor in the death. The findings in a consecutive series of fatal traffic accidents over a period of 3½ years are given in a table, and several cases in which the test proved important are described.

The Technic of Nuclear Sexing. D. J. B. Ashley. Am. J. Clin. Path. 31:230-237 (March) 1959 [Baltimore].

The technique of nuclear sexing is now a well-established research method, and its wide range of applications leads to an increasing flow of requests to the pathologist for this examination. It is the purpose of this paper to describe the methods generally used for this test, and to demonstrate that it is not an esoteric research method to be used only by special departments but is within the scope of the general pathologist. Cells from practically any tissue of the body may be used for "sexing," but it is usually most convenient to use material which may be obtained with minimal discomfort to the patient. The cells of the squamous epithelium of the skin in man are particularly suitable and can be readily obtained either as a formal skin biopsy or by scraping cells from the inside of the mouth.

The sex chromatin body is a mass of heterochromatin, 0.7 by 1.2 μ in mean dimensions. It lies in the nucleoplasm of the cell and is most often located near the nuclear membrane. It stains deeply with the specific nuclear stains, and a deep red-violet by the Feulgen technique, and appears as a small body that is much darker than the remainder of the nucleus. In the usual position, adjacent to the nuclear membrane, it has a planoconvex form with the plane surface closely applied to the nuclear membrane, but if it lies free in the nucleoplasm, it assumes a circular shape. Sex chromatin can be identified in 80 to 90% of the cells of the normal female. Masses of chromatin, morphologically similar to those seen in the female, may be seen in a small proportion of the cells of the normal male. These bodies are not the same as those found in the female, but consist of irregular aggregations of nuclear material. The frequency of these irregular chromatin masses is always less than 10% in the cell nuclei of the male. When the strictest criteria are used, the frequency of identified sex chromatin in the cells of the female is less than 80 to 90%.

An alternative method of diagnosis of genetic sex by means of the cells of the peripheral blood was described in 1954 by Davidson and Smith. These 2 workers demonstrated that a small proportion of the polymorphonuclear leukocytes in normal women had a small projection approximately the same size as the sex chromatin body observed in the somatic cells. This projection, which they termed the "drumstick," was present in at least 6 of every 500 cells in the female, but true drumsticks were never seen in the male. The technique of leukocyte sexing is simple. Films are made from the peripheral blood, preferably on cover slips, and are stained by the routine methods for blood films—Leishman's, Jenner-Giemsa's, or Wright's stain. If 6 or more drumsticks are observed in the examination of 500 polymorphonuclear leukocytes, the patient is regarded as female; if less than 6 bodies resembling drumsticks are observed, the patient is regarded as male. The drumstick is a spherical body, about 1μ in diameter, and is attached to the side of the lobulated nucleus by a thin stalk. Care must be exercised to exclude from consideration small sessile appendages attached to the body of the nucleus by a thick stalk, racquet-shaped bodies that often manifest central vacuolation, and small lobes at the extremities of the nucleus that may be observed in either sex. Many investigators have confirmed the findings of Davidson and Smith, but in a few instances discrepancies have been noted between the results obtained by the leukocyte method and those obtained by the use of somatic tissue cells. Stress is placed on the necessity for experience in the tests and the use of control material.

Behavior of Certain Enzymatic Activities in the Course of Ischemic Syndromes of Obliterating Arteriopathy of Lower Extremities: Aspartic Transaminase, Alanine-Ketoglutaric Transaminase and Phosphoglucomutase. A. Di Simone and G. Ferrante. Minerva chir. 14:123-127 (Feb. 15) 1959 (In Italian) [Turin, Italy].

Serum aspartic transaminase, alanine-ketoglutaric transaminase, and phosphoglucomutase levels were studied in 20 patients, aged between 12 and 73 years, with acute and chronic arterial disease of the lower extremities. Atherosclerosis was present in 18 patients, thromboangiitis obliterans in 6, arteriopathy of diabetic origin in 3, acute thrombosis in 1, postembolic arteriopathy in 1, and arterial lesion probably related to virus in 1. Serum aspartic transaminase and alanine-ketoglutaric transaminase levels rose proportionally with the severity of the disease in patients with arteriopathy obliterans. The values remained within the physiological limits in instances of arteriopathy not associated with ulcerative or gangrenous lesions, they were high in the presence of ulceration or gangrenous states. Very high values of serum aspartic transaminase and alanine-ketoglutaric transaminase activities were observed in patients who had an acute onset of ischemic disorder not necessarily related to a severe necrosis. Of the patients with diabetic arteriopathy. values did not change in 2 with severe arterial lesions but changed in 1 with average severe form of the disease.

The serum phosphoglucomutase level increased, but not as markedly as the levels of the 2 transaminases, in patients who had acute or chronic ischemic disorders associated with extensive tissue degeneration. No changes in the transaminase activity took place in instances of diabetic arteriopathy. However, the values of enzymatic activity were high in 2 patients before amputation of a leg affected by gangrene, but they returned to normal after completed cicatrization. This investigation suggests that there exists a pathological nexus between the variation of serum enzymatic activities and certain types of obliterating arteriopathy, particularly those related to muscular necrosis.

Transformation of a Normal into an Active Breast with Milk Secretion in the Course of Malignant Tumors and After Ovariectomy. G. Piacentini. Policlinico (sez. prat.) 66:249-256 (Feb. 23) 1959 (In Italian) [Rome].

Reactivation of a normal and quiescent mammary gland, accompanied by milk secretion from the breast on mild compression, and hyperpigmentation of the areola and nipple of the breast were observed in 2 women in the course of an advanced phase of malignant neoplastic disease. A nodule on the right side of the inguinal region appeared in one woman at the age of 37 years when she reached the menopause. She had begun to menstruate at the age of 13 and had had 5 normal deliveries. A course of roentgenotherapy had been started 10 months after the appearance of the nodule, at the time that it had started to grow. The nodule enlarged into an ulcerating tumor and was diagnosed as a polymorphous sarcoma. Pulmonary and intra-abdominal metastases appeared 6 months after the completion of the roentgenotherapy. At this stage profuse milk secretion was observed on mild compression of the breast. This anomaly persisted until the patient's death.

A small painful nodule with retraction of the nipple developed in the other woman at the age of 30. She had had 2 children and normal menstruation. A radical mastectomy for carcinoma of the breast and metastases in the axillary lymph nodes was performed a month later. Ovariectomy was done 4 months after the mastectomy. Widespread skeletal metastases were observed a month after the ovariectomy. Carcinomatous metastases were simultaneously revealed in the region of the resected breast. The remaining mammary gland was reactivated and continued to secrete milk until the patient's death.

The author believes that the pituitary body was either the main factor or was subsequently involved in the process of the neoplastic disease in the first patient who had a precocious menopause. In the second patient rapid development of metastases in the bones and skin and lymph nodes, with reactivation of a quiescent mammary gland after ovariectomy, supports the hypothesis of a correlation between malignant neoplastic disease and the activity of glands of internal secretion.

Renal Lesions in Scleroderma: Clinical and Pathological Features. J. D. Tange. Australasian Ann. Med. 8:27-34 (Feb.) 1959 [Sydney, Australia].

Scleroderma is a generalized disease, apparently primarily affecting the small vessels. Since it produces such characteristic and striking changes in the skin, attention was at first attracted to this; however, the presence and importance of visceral, and especially of renal, involvement have now become more widely recognized. The author cites previous investigators, who emphasized the nature and consequences of renal lesions, and then describes observations on 3 patients, who were women ranging in age from 36 to 69 years. The disease lasted 2 years in one of these women and 1 year in each of the others. The terminal phases lasted 6, 12, and 2 weeks, respectively, and were heralded by rising blood pressure and albuminuria. In 2 cases there was papilledema together with retinal hemorrhages and exudates. In the third there was no record of ophthalmoscopic examination, but the course was such that these changes were likely to have been present. Two of the 3 patients received adrenal cortical steroids. In both the blood pressure had already risen before treatment was instituted, but the progress of the disease seemed to be accelerated after the steroid administration.

The significant renal lesion in scleroderma is a mucoid or loose fibrous swelling of the walls of the intralobular arteries, involving the entire wall or the intima alone without inflammatory cell reaction; the lumen is substantially narrowed or obliterated. Interference with cortical blood flow leads to necrosis and thrombosis of the afferent arterioles and focal infarcts of the cortex. Clinically, these changes are mirrored by rapidly progressive renal failure or by severe hypertension or both. The clinical features and the renal lesions closely resemble those described in malignant or rapidly progressive hypertension. Corticosteroids accelerate the progress of the hypertension or may even determine its appearance. Thickening of the basement membranes of the glomerular capillaries is found independently of these arterial lesions. The histories of patients showing this glomerular change suggest that it is probably related clinically to the occurrence of a trace of albumin in the urine, and that the appearance of albuminuria does not necessarily presage the onset of severe hypertension and renal failure. The author suggests that the occurrence of renal failure in 5 of 31 patients who died of scleroderma and the increasing number of reports in the literature permit an estimate of the incidence of these complications.

Sex Chromatin in Cultured Normal and Cancerous Human Tissues. C. P. Miles. Cancer 12:299-305 (March-April) 1959 [Philadelphia].

Cells from 21 tumors obtained from 11 women and 10 men were examined for sex chromatin after the tissues had been cultured in vitro. With 2 exceptions, the female tissues showed sex chromatin in high percentages, while the male tissues did not. There was no significant difference with regard to sex chromatin between normal and cancerous outgrowths from primary explants. It is probable that not all nuclei from female tissues contain sex chromatin clumps. Either the sex clump cannot occur at any point on the nuclear membrane or else the nucleus is not oriented at random with the culture substrate. It may be concluded from this study that at least some malignant tumors from women continue to show sex chromatin in in vitro culture. It is doubtless also a safe inference that these cells possess the sex clumps in vivo, however difficult the demonstration of sex chromatin may be in tissue sections of tumors. The finding that sex chromatin does persist, at least in primary explants, may have experimental as well as clinical value.

RADIOLOGY

Lymphangioma of the Duodenum. J. G. Davis, H. Peck and B. L. Gray. Am. J. Roentgenol. 81:613-615 (April) 1959 [Springfield, Ill.].

The authors present the case of a 65-year-old man who complained of crampy right upper quadrant abdominal pain of 9 months' duration, usually occurring after meals and nocturnally, aggravated by spicy foods, and relieved by eating and drinking milk. He denied nausea, vomiting, melena, jaundice, change in bowel habits, or weight loss. Upper gastrointestinal roentgen-ray examinations revealed a small hiatal hernia and a deformed duodenal cap. In the 4th portion of the duodenum, a circumscribed oval filling defect with intact overlying mucosa was demonstrated. Surgical intervention revealed that the deformity of the duodenal cap apparently was the result of adhesions from a chronically infected gallbladder containing nonopaque stones. In the superior wall of the 4th portion of the duodenum near the ligament of Treitz, a soft, boggy, slightly irregular submucosal mass was found, measuring approximately 3 cm. in its greatest dimension. This appeared grossly benign, and frozen section microscopically revealed a lymphangioma.

Only 10 cases of lymphangioma of the gastrointestinal tract have been described in the English literature. There have been no previous reports of lymphangioma in the duodenum. Lymphangioma is one of the least frequent of the benign tumors of the small intestine. It is thought to arise from the lymphatic plexus in the submucosa into which the lacteals of the villi empty. Many believe the tumor develops from misplaced embryonic tissue, but evidence to support this is lacking. A more plausible cause seems to be stasis and back pressure brought about by blockage from the mesenteric lymph nodes. Tumors of the small intestine may or may not be symptomatic. If symptoms are present, they can be of 3 types: (1) obstructive; (2) bleeding; and (3) symptoms arising from local irritability, such as ulcer-like pain, vague signs of indigestion, nausea, belching, and occasionally vomiting. Intussusception may be found. The roentgenologic aspects of lymphangioma are those of a submucosal intramural tumor, usually with overlying intact mucosa.

Six Primary Adenocarcinomas of the Colon Occurring Simultaneously: Report of a Case. W. Molnar. Am. J. Roentgenol. 81:678-682 (April) 1959 [Springfield, Ill.].

Studies based on large numbers of collected cases show that the average incidence rate of multiple malignant lesions of the colon is between 3 and 4%. Old age apparently is not a factor in the occurrence of multiple lesions, since the mean age for such patients is less than for patients with single lesions. Adenomatous polyps are believed by many authors to be precancerous lesions because of the higher incidence of benign polyps associated with malignancy. Predisposition or "inherent susceptibility" to cancer seems to be the most important single factor in the production of multiple malignant lesions of the colon. The case presented was that of a 75-year-old diabetic woman, who had had adenocarcinoma of the endometrium in 1944. This lesion had been treated by irradiation, followed by hysterectomy. In 1953 the patient complained of having had midabdominal pain since the preceding month, associated with nausea and vomiting during the last 3 days. A supine roentgenogram of the abdomen on the day of admission showed markedly distended ileal loops as well as distention of the proximal colon. After the abdomen had been decompressed with the aid of a Miller-Abbott tube, an examination with the use of barium showed a polypoid mass involving a 5-cm.-long segment in the midportion of the elongated sigmoid. There was another small mass in the region of the splenic flexure. A 7-cm. segment of the hepatic flexure narrowed down to an irregularly outlined, rigid channel, causing delay in filling of the ascending colon with barium. Spot roentgenograms taken of these 3 lesions showed the details of the tumors. The 14-by-17-in. roentgenograms of the filled colon demonstrated another rounded mass, 4 cm. in diameter, at the medial aspect of the cecum, which was believed to represent lipoma of the ileocecal valve. The advanced lesions in the hepatic flexure and in the sigmoid were obscured because of the tortuosity of these segments. At follow-up examination by air-contrast study, 2 additional polypoid lesions were visualized, one in the proximal sigmoid and another in the region of the midtransverse colon.

At laparotomy only 4 lesions were palpable, besides the lipoma in the ileocecal region. Although a total colectomy was contemplated, the procedure had to be terminated after the resection of all the colon proximal to the midsigmoid. The patient died on the same day. The distal half of the sigmoid and the rectum were examined at autopsy. The lesions varied in size. The most advanced carcinoma in the hepatic flexure was the most proximally located, implicating cellular seeding as a possible explanation for the development of the smaller-sized and less-advanced lesions in the left side of the colon. There was no evidence of concomitant adenomatous polyps on the removed specimen. No other similar case report could be found in the English literature.

PUBLIC HEALTH

Two Epidemics of Injection Diseases. H. C. Zanen. Nederl. tijdschr. geneesk. 103:271-276 (Feb. 7) 1959 (In Dutch) [Amsterdam].

In 1951 hepatitis was declared to be a notifiable disease in the Netherlands, and from 1951 to 1957 a total of 4,276 cases of infectious hepatitis and 45 cases of serum hepatitis were reported in Amsterdam. Every patient with hepatitis was subjected to a thorough epidemiologic investigation with regard to blood transfusions, skin tests, or any type of injection (including those performed by a dentist) during the 6 months preceding the onset of their hepatitis. The patient was questioned also about the occurrence of other cases of jaundice in his environment. These inquiries revealed that, in 419 of the patients with hepatitis reported, one of the aforementioned interventions had been carried out during the 6-month period; no other cases of hepatitis had occurred in the environment, so that a diagnosis of serum hepatitis seemed possible in about 10% instead of in only 1% of the patients. In classifying the patients according to age, it became apparent that in those more than 40 years old about 50% could have had serum hepatitis. Further analysis of the types of treatment received and of the places in which the treatment had been carried out revealed that a large number of hepatitis patients had received treatment at one particular outpatient clinic. It was ascertained also that, during periods when work was pressing, the nursing staff of this clinic changed the needle but not the syringe, when drawing blood for the determination of the erythrocyte sedimentation rate. When a sterile needle and syringe were used for every patient, no new cases of hepatitis developed.

In the course of immunizations of school children against diphtheria, inflammatory reactions were found to be more frequent than usual. In one school abscesses developed in 6 of 77 children who had been inoculated. Hemolytic streptococci, group A, type 12/27/44, were isolated from 3 of these abscesses. Scarlet fever was diagnosed in one child one day after the immunization. The abscesses were attributed to accidental contamination of a common filling-needle. It is pointed out that the use of a common filling-needle for a number of injections constitutes a potential danger of infection and is to be condemned.

How Did They Die? A Study on the Occupational Mortality in Three Swedish Professions. E. Ask-Upmark. Acta med. scandinav. 163:89-104 (no. 2) 1959 (In English) [Stockholm].

This study was originally started to ascertain the cause of death in university professors, because 2 famous professors in the linguistic sciences had died of malignant glioma of the brain, and a noted pathologist is said to have ascribed the preponderance of gliomas in males to their cerebral activities. In an earlier study the author had been able to demonstrate the predilection of gliomas for the more recently developed parts of the hemisphere, the regions of human achievement. Yet the strain on the vascular system of the brain might be presumed to be considerable in a mental worker, and the question had to be answered whether vascular lesions were more frequent in the brains of scholars. The author compared the mortality in 382 Swedish university men, 508 Swedish printing workers, 741 Swedish street-car employees, and 700 American physicians. (Data on the last group were obtained from The Journal). All were males, and no case of death under 30 was included. The records for the 4 groups covered different periods: those for the Swedish university men, the years from 1900 to 1957; for the printers, 1925 to 1955 (with some exceptions); the street-car men, 1944 to 1956; and the American physicians, the year 1957.

The Swedish university men did not present any increased incidence of cerebrovascular lesions or of intracranial neoplasms. The incidence of tuberculosis and suicides was rather on the low side. The incidence of pulmonary carcinoma was strikingly low (2 cases). Otherwise the causes of death in the professors were about the same as those in the average population. The printers died, on an average, 10 years younger than the university men; yet malignant tumors accounted for a large percentage of their deaths. Bronchial carcinoma was particularly frequent during the last 9 years, accounting for 15 of 267 deaths. Tuberculosis also accounted for a strikingly large number of deaths among the printers, but vascular lesions of the brain were less frequent than in other groups. Street-car men at the time of death were, on an average, 7 years younger than the university men but 3 years older than the printers. Malignant tumors were just as common in this group as in the group of printing workers, although the proportion of bronchial carcinomas was less pronounced. A striking feature, as yet unexplainable, was the high incidence of intracranial tumors, and suicides were rather more common than in the average population. The American physicians served as a control group. Their average span of life approached that of the Swedish university men. The most striking feature was the high incidence of cardiovascular deaths, amounting to more than 50% of all deaths, 3 out of 4 cardiac deaths being due to coronary lesions.

The author concludes that the Swedish university men died of essentially the same causes as did men in the general population. There was not the slightest evidence that the work of the scholar would predispose to the development of cerebral disease. The average age of the university men exceeded that of the more manual workers, and bronchial carcinoma as a cause of death was strikingly rare.

Profile of American Families, 1940-57. W. F. Pratt. Pub. Health Rep. 74:189-194 (March) 1959 [Washington, D. C.].

The author shows that marked changes are occurring in the patterns of American family life, many of which have proceeded more rapidly since World War II. The number of families in the United States has increased. More than three-fourths of the decline in the proportion of the population "never married," since 1890, occurred between 1940 and 1957. In this period the proportion of men currently married increased from 59.7 to 67.3%, and of women from 59.5 to 66.4%. The number of families increased 35.1% between 1940 and 1957. Several factors have contributed to this increase in families: 1. More couples survive to celebrate their golden wedding anniversary. 2. The proportion of remarried persons has increased. 3. The proportion of persons remaining single has declined. 4. Better economic conditions have contributed to the increase of families by decreasing the "doubling-up" in households.

In commenting on fertility rates, the author says that parents today apparently want, or can afford, to care for more children. In 1956 the fertility rate reached 120.8 infants born alive per 1,000 women, 15 to 44 years of age, which is in sharp contrast to the 1940 rate of 79.9 and is in excess of the 1947 rate of 113.3, the year of the "baby boom." Most important for trends in family size is that the increase in fertility rates in recent years has been due to increasing rates of third and higher order births, which have continued to rise since 1950. However, despite the marked increase in fertility and children born, the average size of families has increased but little and only in the last few years.

Changes in the household and family situation of persons over 65 years of age have been small, but in the direction of increasing isolation from kinsfolk. Between 1950 and 1957 the proportion of persons over 65 who were classified as unrelated individuals or inmates of institutions increased from 23.5 to 24.8%, or by 3,645,000 persons.

The social and economic conditions of families have generally improved throughout the period 1940-1957. This has been largely due to the increasing number of families with more than one earner and especially to the increase of women in the labor force. Despite the increasing number of dependent children in families, the participation of married women in the labor force has increased. On the basis of available data, it is extremely difficult to assess the trend in family stability, but the increasing proportion of remarried persons and the increasing proportion of divorced persons suggest a growing problem of family instability. While many of the trends in American family life, especially since World War II, may be regarded as encouraging, sight must not be lost of the fact that many social problems thought to be closely related to family life have been increasing. These are juvenile delinquency, mental illness, illegitimacy, and living conditions and productive opportunities for elder citizens. A basic step in understanding these problems and effecting preventive techniques lies in a more detailed study of the family as the unit of social, mental, and physical health. The author cites the need of more centralized registration as well as more intensive study of health conditions and of the functions of the family in rehabilitation and in preventing and treating illness.

BOOK REVIEWS

Textbook of Surgery. Edited by H. Fred Moseley, M.A., D.M., M.Ch., Assistant Professor of Surgery, McGill University, Montreal, Canada. Third edition. Cloth. $17. Pp. 1336, with 846 illustrations. C. V. Mosby Company, 3207 Washington Blvd., St. Louis 3; Henry Kimpton, 134 Great Portland St., London, W. 1, England, 1959.

This edition continues to be one of the leading single-volume references in the field of surgery for the medical student, surgical intern, and resident. It contains the work of 40 contributors, some of whom are new and others of whom have drastically revised and improved the sections involving their field of interest. This textbook is copiously illustrated, excellent use being made of the Ciba collection. Many of the plates are in color. The type is clear and easily readable. The chapters which have been added, particularly the section on pediatric surgery, are a great asset to this edition. Other excellent presentations to be noted are the sections on fractures, cardiovascular surgery, the evolution of modern surgery, the diagnosis of the acute abdomen, and pancreatic disease.

If any constructive criticism might be offered for future editions, it would be in the sections on thyroid carcinoma, parathyroid disease, and the surgical management of duodenal ulcers. Much recent experimental work and commentary in these areas has been excluded from this textbook which might have clarified the presentation in these fields. The sections on peripheral vascular diseases are extremely well done, except that on the treatment of peripheral embolization. Immediate operation appears to produce better results as regards limb salvage and usefulness than any conservative measures. The student of surgery is interested in comparative statistics, particularly as pertains to the surgical treatment of carcinoma in varied areas. This edition might benefit by more attention to this item in the future. Despite these minor shortcomings, the book is worthy of the attention of medical students, interns, and residents in the field of surgery.

Bacteriophages. By Mark H. Adams. With Chapters by E. S. Anderson, J. S. Gots, F. Jacob and E.-L. Wollman. Cloth. $15. Pp. 592, with 17 illustrations, electron micrographs by E. Kellenberger, Interscience Publishers, Inc., 250 Fifth Ave., New York 1; Interscience Publishers, Ltd., 88-90 Chancery Lane, London, W. C. 2, England, 1959.

This book should be welcomed by all whose attempts to keep pace with the rapid developments in modern bacteriophage research have been frustrated by an overwhelming array of special articles and reviews. This is the first attempt in over 30 years to bring the knowledge of bacterial viruses under one cover. The book was essentially completed by the author before his untimely death. Its eventual posthumous publication was made possible through the cooperation of a number of specialists who helped to edit the completed chapters and finish the uncompleted ones. The result is a well-written book. With remarkable ease of presentation and readability, a complete perspective of the field is unfolded. The bacterial viruses are first considered as organisms; their chemical, morphologic, and antigenic properties and how they are affected by physical and chemical agents is described. Then follows a detailed account of various phenomena which result from the interaction of the bacteriophages with their hosts. Phage genetics, lysogeny, colicins, phage typing, and taxonomy are also considered. A glossary and valuable appendix covering methods and techniques complete the volume. This book should be of special interest to all students of virology, bacteriology, biochemistry, and genetics. Those who are involved in any phase of virus research should find it a welcome addition to their bookshelves.

Klinische Methoden der Blutgerinnungsanalyse. Von Prof. Dr. J. Jürgens und Doz. Dr. F. K. Beller. Mit einem Geleitwort von Prof. Dr. M. Gänsslen, Direktor der II. Medizinischen Universitätsklinik Frankfurt am Main. Plastic. 56 marks; $13.35. Pp. 391, with 104 illustrations. Georg Thieme Verlag, Herdweg 63, (14a) Stuttgart, West Germany; [Intercontinental Medical Book Corporation, 381 Fourth Ave,. New York 16], 1959.

The advances in the understanding of the physiology and pathology of blood coagulation have been bewilderingly rapid in recent years. Even the experts in the field have difficulty keeping pace. The others, including scientists in related fields and clinicians, have all but given up hope of being able to maintain an understanding of and a critical point of view in relation to these important developments. This is probably the reason for the large number of monographs on this subject written from various points of view. The present contribution is an attempt by two distinguished German investigators to give a comprehensive and critical review of the present-day knowledge of this subject.

As indicated in the title, the emphasis is on techniques. The first chapter deals with the modern concepts of the physiology of blood clotting, which consists of an initial prophase and four phases. During the prophase, active thromboplastin is formed from platelets and plasma factors. Conversion of prothrombin to thrombin, of fibrinogen to fibrin,

---

These book reviews have been prepared by competent authorities but do not represent the opinions of any medical or other organization unless specifically so stated.

clot retraction, and fibrinolysis take place in the four phases of coagulation. The role of inhibitors in all but the third phase is described. The presentation of this complex part of the subject is up to date with relatively few defects. For example, on the basis of a paper published in 1949, Quick is quoted as designating the factor VII principle as a special inactive precursor of prothrombin. This point of view was given up by Quick several years ago.

The second chapter deals with disorders of coagulation. Several practical and important topics including changes of coagulation in various diseases, the use of the artificial kidney, problems met in the use of extracorporeal circulation, diagnosis of impending thrombosis, and anticoagulant therapy are discussed. The equipment of the coagulation laboratory is presented in a brief chapter. Then follow 12 chapters on technique including quantitative and qualitative examination of platelets; plasma factors involved in the prophase and first phase of coagulation; tests for determination of fibrinogen, the fibrinolytic system, coagulation time, and clot retraction; the mathematics of calculation of clotting factors; the steps involved in the elucidation of the causes and in the differential diagnosis in a patient with a hemorrhagic disorder; tests for heparin; and the preparation of the many delicate reagents used in coagulation studies. The bibliographic references are as complete as one would wish. The paper, binding, print, and illustrations are of high quality. The book can be recommended as a most useful source of information to clinicians, pathologists, investigators, and students of blood coagulation.

Diseases of Women. By ten teachers under direction of Frederick W. Roques, C.B.E., M.D., M.Chir. Edited by Frederick W. Roques, John Beattie, and Joseph Wrigley. Tenth edition. Cloth. $8. Pp. 556, with illustrations. Williams & Wilkins Company, 428 E. Preston St., Baltimore 2; Edward Arnold (Publishers) Ltd., 41-43 Maddox St., London, W. 1, England, 1959.

The first edition of this book appeared 40 years ago and was written primarily as a textbook for use by medical students. The present editors have brought the book up to date by including data on vaginal cytology and by rewriting the sections on genital prolapse, tuberculous salpingitis, and gynecologic operations. This edition contains 75 pages more than the previous one. In general, the arrangement of the subjects is the same as before. Because the 10 contributors are experienced gynecologists and teachers the book contains a large amount of practical and useful information. It is well written and abundantly illustrated. It is questionable whether the 48 pages devoted to gynecologic operations should have been included in a book written primarily for medical students. Among the operations described and illustrated are such unusual operations as radical excision of the vulva, construction of an artificial vagina, enlargement of the vaginal introitus, the "sling" operation, and radical abdominal hysterectomy for carcinoma of the cervix. In spite of this minor criticism undoubtedly the book will continue to be popular.

The Physiopathology of Cancer. By 32 authors. Edited by Freddy Homburger, M.D. [First edition edited by Freddy Homburger and William H. Fishman.] Foreword by Joseph C. Aub, M.D., Sc.D. Second edition. Cloth. $33. Pp. 1180, with 189 illustrations. Paul B. Hoeber, Inc. (medical book department of Harper & Brothers), 49 E. 33rd St., New York 16, 1959.

The four parts of this book deal with the biology of cancer, the chemistry and physics of cancer, clinical investigations into the etiology and endocrinology of cancer, and some practical applications of the foregoing in chemotherapy, diagnostic exfoliative cytology, and radiation therapy. The amount of information presented is overwhelming, and the book is not one to be read continuously from cover to cover. Perhaps its size is a good omen, presaging a breakthrough in cancer research, for it reminds one of the large volumes on glycosuria and carbohydrate metabolism that reflected the unhappy state of diabetes research just before the discovery of insulin in 1922.

A few criticisms are offered as suggestions to prospective authors of similar works and to the present authors in case future editions are contemplated. The statistical formulas in this book are not always set up in a way that enables the reader to tell whether a succession of two or more letters denotes the product of two or more quantities or simply represents the abbreviation for a single quantity. The index is rendered tricky by overclassification, so that one finds "plutonium" and "thorium," for example, not under P and T but under C for "carcinogens." Neither the index nor the table of contents helps the reader to locate discussions of such important questions as the existence of precancerous lesions or the alleged carcinogenic action of smegma. These faults, together with some unevenness of space-allocation for various subjects, detract but slightly from an otherwise splendid piece of work. Copious bibliographies follow each chapter. The book should be valuable to everyone engaged in research on the rapidly developing subject of cancer.

Progressive Exercise Therapy in Rehabilitation and Physical Education. By John H. C. Colson, F.C.S.P., M.S.R.G., M.A.O.T., Principal, School of Remedial Gymnastics and Recreational Therapy, and Director of Rehabilitation, Pinderfields Hospital, Wakefield. With foreword by J. M. P. Clark, M.B.E., M.B., Ch.B. Cloth. $4.50. Pp. 184, with 174 illustrations. Williams & Wilkins Company, 428 E. Preston St., Baltimore 2; John Wright & Sons, Ltd., 42-44 Triangle West, Bristol 8, England, 1958.

Except for brief explanations of the conditions for which they are prescribed this book consists almost entirely of exercise directions and diagrams.

The volume is divided into three parts dealing with (1) progressive exercises for the various body parts, (2) specific exercises for use in certain postoperative conditions, and (3) general exercises for supplementary conditioning. In the first section, the progression is developed by classifying the exercises as elementary, intermediate, and advanced with gradations within each of these groups. Exercises for specific therapy are grouped in primary and secondary categories and also in terms of their use at various periods during recovery and rehabilitation. General exercises include warming up exercises, which may be done to music, and "circuit training" routines, which employ a set of consecutively numbered exercises which each performer repeats according to his ability. Exercise gradations are developed with consideration for both strength and mobility. While the progressions apparently are carefully developed on the basis of wide clinical experience, they in no way obviate the need for prudent individual prescription of the exercises. No system of gradation can take the place of painstaking attention to the individual needs of the patient on the part of the physician and physical therapist. Used in this way the progressions should be helpful in planning treatment and rehabilitation programs.

The Investigation of the Relative Function of the Right and Left Lung by Broncho-Spirometry: Technique, Physiology and Application. By Frank Bergan, M.D. Paper. $4.50. Pp. 145, with 85 illustrations. Grune & Stratton, Inc., 381 Fourth Ave., New York 16; 15/16 Queen St., Mayfair, London, W. 1, England, 1957.

This excellent monograph describing the technique, physiology, and applications of bronchospirometry is by the assistant surgeon in charge of the University Institute for Respiratory Physiology in Oslo, Norway. In many situations, particularly where an operation is contemplated or has been performed, it is important to know the respiratory function of each lung. Bronchospirometry provides this information, but the technique of intubing each main bronchus and of getting an accurate and reliable test is so difficult that the procedure is rarely used and more rarely used well. Realizing this, the author has described his technique in detail, listing the difficulties he has encountered and the manner in which he has overcome them. Among other things, he has devised a bronchospirometer tube which is well tolerated and which can be easily constructed. The remainder of the book is devoted to a report of studies on the effect of position on the function of each lung and to the application of the method in preoperative and postoperative studies. The volume is an important contribution, particularly because of the detailed description of the technique of this valuable but difficult procedure.

Pathogenesis and Treatment of Parkinsonism: Sixth Annual Scientific Meeting of the Houston Neurological Society, Texas Medical Center, Houston, Texas. Compiled and edited by William S. Fields, Professor and Head, Division of Neurology, Baylor University College of Medicine, Houston. Cloth. $10.75. Pp. 372, with illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 24-25 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, Canada, 1958.

Such a comprehensive review of the most recent concepts of hyperkinetic disorders has been eagerly awaited by those interested in these diseases. This volume resulted from the symposium held by the Houston Neurological Society in March, 1958. The material is so presented as to delineate clearly what is known about these disorders, while at the same time the reader is made aware of the general misconceptions and dilemmas that persist in regard to Parkinsonism and related entities. Problems of epidemiology and basic experimental studies relating to the genesis of tremor and other hyperkinetic phenomena are discussed. A section on the pathology of Parkinsonism points out the problems involved and the heterogeneous histological changes that may be found. Information on the inclusion bodies previously described by Lewy in these diseases is also included. A historical review of the surgical attempts to alleviate the various abnormal movements and alterations in tone associated with these diseases provides additional color. The advantages of surgical procedures such as cortical excisions, pallidoansotomy, chemopallidectomy and thalamectomy, anterior choroidal artery occlusion, and the more recent ultrasonic irradiation techniques are described in the closing chapters. The controversy about the role of the corticospinal tract in tremor is aired in this volume and should prove exciting to the reader. This volume should prove valuable to all who are interested in the hyperkinetic disorders.

VA Prospectus: Research in Aging. Cloth. $1.50. Pp. 125, with 48 illustrations. Superintendent of Documents, Govern. Print. Off., Washington 25, D. C., 1959.

The brevity and high quality of this monograph should make it appeal to more readers than some of the recent more lengthy publications on similar subjects. This is a collection of the papers and comments of the participants in a conference called by the Veterans Administration Advisory Committee for Problems of Aging, May 16, 1958. Since diseases associated with aging account for a rapidly increasing proportion of the Veterans Administration hospital population, essential elements of current medical knowledge and thoughts concerning aging are presented in order to focus better the future research projects on aging within the Veterans Administration. Research on the aging of the molecules is discussed by Isidore Gersh and research on aging of the cells by Robert J. Boucek.

The volume goes on to a discussion of research on the organs by James E. Birren, research on persons by Charles F. Geschickter, and research on groups by Jack Weinberg. This list of contributors attests to the high quality of the monograph.

Surgery of the Sympathetic Nervous System. By Professor Sir James Paterson Ross, K.C.V.O., LL.D., M.S., Director of Surgical Professorial Unit, St. Bartholomew's Hospital, London. Third edition. Cloth. $8. Pp. 170, with 51 illustrations. Williams & Wilkins Company, 428 E. Preston St., Baltimore 2; Baillière, Tindall & Cox, 7 & 8 Henrietta St., Covent Garden, London, W. C. 2, England, 1958.

In this concise, readable book the drawings are simple and pertinent to the text. The author has had over 30 years' experience with surgery of the sympathetic nervous system and is well aware of its limitations. The section on anatomy and physiology is brief and well organized. The description of Raynaud's disease is excellent and the limitations in surgical treatment are given. The various operations for essential hypertension are discussed and realistic criteria on which patients should be selected for this operation are given. Other conditions discussed include hyperhidrosis, causalgia, and pain. The technique of sympathectomy is described and illustrated. The author's purpose in writing this book was to indicate that there is a rational basis for every sympathectomy and he has succeeded. This book should have its greatest use by those surgeons who are frequently asked to consider one of the operations on the various parts of the sympathetic nervous system for the myriads of conditions that are affected by the autonomic nervous system. Both the usefulness and the limitations are honestly stated.

Treatment of Lung Cavities and Endobronchial Tuberculosis, with Special Reference to Treatment in Malaya. By Beryl E. Barsby, M.D., M.R.C.P. Boards. $4.75. Pp. 147, with 46 illustrations. Williams & Wilkins Company, 428 E. Preston St., Baltimore 2; E. & S. Livingstone, Ltd., 16 & 17 Teviot Pl., Edinburgh 1, Scotland, 1959.

This small volume records the experiences with pulmonary tuberculosis by physicians of excellent qualifications under primitive conditions in Malaya as it is today, a country of widespread disease. The experiences of the staff physicians at the General Hospital at Johore Bahru are recorded in detail. The authors elucidate a condition first described by Carswell in 1838 and about which Zurik noted "Even in 1954, the true involvement of the trachea and bronchi in pulmonary tuberculosis is far from clear, . . . its frequency is still greatly underestimated." Some physicians, although aware of the condition, are not fully conversant with the important part it plays in the treatment of the patient. Even if surgery is not contemplated, the author hopes that this work will clarify certain points and help other workers in the field to understand some of the problems which confront the physician. This study was confined to adults among a population suspicious of modern methods of treatment. Though the patients were later extremely cooperative, a full follow-up system was difficult to attain in a country where communications are poor by modern standards.

The chapters are comprehensive and deal with the social background of Malayans; hospitals, the people, epidemiology, and the problem of endobronchial tuberculosis; histology related to bronchoscopic appearances; incidence of disease; symptoms and signs; pathogenesis; radiologic observations; physiological relationship of bronchial tuberculosis and cavities; effects of drugs; healing and treatment; management of cavities; surgical aspects; management of pyopneumothorax; anesthesia for bronchoscopy; and physiotherapy. This book deserves reading by virtue of its fine observations on endobronchial tuberculosis, its clear description of an area rampant with tuberculosis, and its good quality throughout.

Safe Handling of Radioisotopes. Safety series no. 1. [Also published in French, Russian and Spanish.] Paper. $1; 6 shillings; 350 French francs. Pp. 99. International Atomic Energy Agency, Kärtner Ring, Vienna I, Austria, 1958.

This booklet offers detailed and specific instructions for the handling of both sealed and unsealed sources of ionizing radiation. The importance of organizing, planning, monitoring, and record-keeping is stressed in the introduction. Valuable technical hints are given as to shielding, design of work places, protective clothing, ventilation, storage, transportation, and waste disposal. Two special sections deal with accidents and decontamination. Appendix I gives the accepted figures for permissible doses of radiation with definitions of the terms and units essential in applying the data. Appendix II gives maximum permissible levels for surface contamination of equipment, work places, clothing, and skin. The book dispenses with illustrations, but readers will appreciate the succinctness of the text.

Pathology. By Peter A. Herbut, M.D., Professor of Pathology, Jefferson Medical College and Director of Clinical Laboratories, Jefferson Medical College Hospital, Philadelphia. Second edition. Cloth. $18.50. Pp. 1516, with 1506 illustrations. Lea & Febiger, 600 S. Washington Sq., Philadelphia 6, 1959.

This edition has been increased by 288 pages and 213 photographs. The portions on the general pathological processes have been revised with greater emphasis on mechanisms and pathological aspects. A section on the systemic pathology of the organ or system discussed has been added at the beginning of each chapter. Wherever possible the subject material has a brief summary of the normal physiology; a discussion of specific and less specific deviations from the normal; a correlation, when possible, of morphology and physiology; and a discussion of tests by which altered physiological function can be discerned. The large content of text material is presented in 40 chapters, 7 of them devoted to general pathology as follows: orientation, the autopsy, congenital anomalies, degeneration, *inflammations*, physical disturbances, and tumors. The chapters on systemic pathology deal with the heart; vessels; upper respiratory system; larynx; lower respiratory system; thyroid; parathyroids; upper digestive system; esophagus; stomach; small intestine; appendix; colon; liver and biliary system; pancreas; peritoneum; reticuloendothelial system; blood; spleen; lymph nodes; thymus; adrenals; lower urinary system; breast; bones; joints; fascias, tendons, and bursas; skeletal muscle; skin; and central nervous system. Each chapter has detailed instructions or descriptions pertinent to the topic. The book is well written in a clear direct style; the illustrations are well chosen and of good quality. Suitable bibliographies are given at the close of each chapter. The book is recommended to students in medical schools, residents in specialized training in pathology, and others.

The Treatment of Diabetes Mellitus. By Elliott P. Joslin, A.M., M.D., Sc.D., Physician, New England Deaconess Hospital, Boston, Howard F. Root, M.D., H.H.D., Medical Director, Joslin Clinic, Priscilla White, M.D., Sc.D., Physician, New England Deaconess Hospital, and Alexander Marble, A.M., M.D., Physician, New England Deaconess Hospital. With cooperation of Dr. Robert F. Bradley and others, and associates in Joslin Clinic and Baker Clinical Research Laboratory, New England Deaconess Hospital. Tenth edition. Cloth. $16.50. Pp. 798, with illustrations. Lea & Febiger, 600 Washington Sq., Philadelphia 6, 1959.

Joslin's book continues to be the vade mecum of the physician interested in diabetes. Strictly speaking, it is less Joslin's book than it used to be, for in addition to the co-authors of the earlier editions there now appear a number of new collaborators. Several chapters, however, were written by the senior author alone. They bear his unmistakable imprint and remind one that he has his hand firmly on the helm. This very useful book represents an accumulated experience with more than 50,000 diabetic patients; an experience extending back into the last century, yet it is fully up to date in its inclusion of the latest developments. Among the new contributions are those on physiology by Renold, and on acidosis by Nichols and Root, which are outstanding. The oral methods of treatment are discussed competently and conservatively by Marble and Krall. The degenerative complications receive much attention, since cardiovascular-renal disease has increased steadily, and now accounts for 77.7% of all deaths of diabetic patients. Ditzel, a co-author of the chapter on ocular disease, has studied the small vessel pattern of the bulbar conjunctiva of living subjects with the aid of the stereoscopic dissecting microscope. He describes abnormal patterns in children who have incipient diabetes long before retinopathy is discernible and in 35 to 43% of children of diabetic mothers, as well as in both younger and older patients, with well-established diabetes.

The Joslin group has yielded no ground in its contention that good control of glycosuria tends to prevent vascular disease, while poor control favors it. In support of this contention, they cite their "Victory medal" patients, now numbering 88, who have had well-controlled diabetes for 25 years or more and show no such complications. They refer also to impressive studies reported previously, in which most long-term patients under good control were found to have little or no retinopathy or nephropathy, while most of the poorly controlled patients had severe lesions. Here, however, as in the original reports, the authors regrettably take no cognizance of the sizable minority which, in each group, constitutes an important exception to the rule and in whom factors other than control must be involved. If it is true that dietary fat plays some role in the genesis of atherosclerosis, it would seem to have special pertinence for the diabetic, who has a tendency toward hyperlipemia, anyway, and whose fat intake traditionally has been high because the carbohydrate intake has been low. Such considerations lead the authors to recommend that calories from fat be kept at less than 40% of total calories and that polyunsaturated fats replace animal fats to as great an extent as is feasible. More drastic modifications of diet are not advised.

The book has very few faults. There is some duplication of material in chapters written by different authors, but this is hardly objectionable. The maximum activity of protamine zinc insulin is given as occurring at 8 to 12 hours in one place (page 285) and 12 to 24 hours in another (page 664), the latter being more in accord with general experience. An undue amount of space is given to trauma. The chapter on pregnancy, in which the case for the use of female sex hormones is presented in somewhat new form but with undiminished enthusiasm, is rather dogmatic in some places and occasionally clarity and readability seem to have been sacrificed for brevity.

A Practice of Thoracic Surgery. By A. L. d'Abreu, O.B.E., Ch.M., F.R.C.S. [Second edition.] Cloth. $19. Pp. 619, with illustrations. Williams & Wilkins Company, 428 E. Preston St., Baltimore 2; Edward Arnold (Publishers) Ltd., 41-42 Maddox St., London, W. 1, England, 1958.

The beauty of science is that it is rarely static and never complete. The fault inherent in all textbooks is that they present the subject as it was a year or more before the date of publication. This does not mean that textbooks are not necessary. For the student and for the busy practitioner they provide a compact body of knowledge which, if the particular science is not progressing too rapidly, will give them a basic understanding of the subject and serve as a basis for their reading in the current literature. The ideal textbook avoids this fault and fulfills its purpose by presenting each subject historically, showing how and why it has evolved, and by so doing emphasizing the fact that it *is* still evolving; its great virtue lies in its complete bibliography and in the skill with which a body of literature has been digested and condensed. This type of textbook is a labor in objective scholarship. There is another type of medical textbook, of which the work under discussion is an excellent example, which is also valuable; it presents the current practice and opinion of a single person or of persons connected with a clinic. If these persons are abreast of the times and have the wide experience afforded by years of practice, the textbook should be good. It should be valuable to the student and also of great interest and value to those practicing the specialty of thoracic surgery.

In the introduction to this book, the author states frankly that it is "a" practice of thoracic surgery and not "the" practice. Because he is familiar with what has been done and said in this field and because he has had a wide experience in it, the book presents a good picture of the subject as it is practiced throughout the world. No thoracic surgeon will find much to disagree with or criticize. Everyone, however, is bound to discover some points which, in his opinion, are minor sins of omission and commission. Too little space has been devoted to crushing injuries of the chest. No mention is made of soft tissue traction or the use of the mechanical respirator. In discussing thoracoplasty for pulmonary tuberculosis, the author fails to mention subscapular extraperiosteal paraffin plombage and he is perhaps too ready to classify artificial pneumothorax as a permanently obsolete procedure. These are minor criticisms. This major contribution is excellently written and the illustrations are good and adequate. It is probably the best textbook on the subject of thoracic surgery available today.

Pharmakologie als theoretische Grundlage einer rationellen Pharmakotherapie. Von Knud O. Møller, Professor der Pharmakologie an der Universität Kopenhagen. [Third German edition translated and edited from fifth Danish edition by O. Walker.] Cloth. 65 Swiss francs; $16.25. Pp. 902, with 50 illustrations. Benno Schwabe & Co., Basel 10, Switzerland; [Intercontinental Medical Book Corporation, 381 Fourth Ave., New York 16], 1958.

This is the third German edition, prepared from the fifth Danish edition, of a magnificent textbook of pharmacology. The preface lists the many sections that have been added since the second German edition. The list, too long to reproduce here, includes insect repellents, detergents, emulsifiers and macrogoles (polyethylene glycols of various molecular weights), antimorphines, new urea derivatives, carbonic anhydrase inhibitors, new antidiabetic drugs, ion exchangers, phenindione and other new anticoagulants, and tetracemin and other new chelating agents. Many other sections have been drastically revised. There is an up-to-date bibliography and a good index. In spite of the large size of the work and the rapid rate of change in its subject matter, the facts have been well assimilated and are clearly presented. The simple directness of the German does credit to the translator and will be appreciated by American readers. The book merits the attention of pharmacologists everywhere.

Tuberculosis and Other Communicable Diseases. [Edited] by J. Arthur Myers, M.D., Professor of Internal Medicine and Public Health, Medical, Public Health and Graduate Schools, University of Minnesota, Minneapolis. With introduction by Irvine McQuarrie, A.B., Ph.D., M.D. Cloth. $14.50. Pp. 499, with illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 24-25 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, Canada, 1959.

When the countless advances by medical science during recent decades are appraised in the light of their total impact on human welfare, the most impressive and significant will be concerned with the field of infectious diseases. Many of these achievements are reviewed in this volume in contributions by leaders in their special subjects. The editor is a well-known specialist in public health and preventive medicine whose studies in tuberculosis are outstanding. The present volume fulfills the desire to center attention on the communicable nature of tuberculosis and comparable infectious diseases. This and the concept of early recognition and prompt isolation in prevention of such diseases should make the volume useful to the medical student and practitioner, as well as a textbook in nursing and public health courses. Much preventive work remains to be done even though diagnostic, therapeutic, prophylactic, and epidemiologic measures are well established. None of these diseases has been eradicated and many remain constant threats to every community. Myers cites a smallpox epidemic with 300 deaths, due to lack of information, economic situations, and cultists who opposed preventive measures. If the information presented in this book is adequately disseminated and used, people may live longer, more happily, and more efficiently than preceding generations. The chapters cover tuberculosis, systemic mycoses, acute respiratory diseases, viral diseases, brucellosis, common cold, poliomyelitis, rheumatic fever, meningitis, impetigo, gonorrhea and syphilis, and others. The volume should be in demand among medical students, general practitioners, nurses, public health workers, and all concerned with communicable diseases. It is presented in simple and plain language.

QUESTIONS AND ANSWERS

LIGHTERS AS LUNG CANCER FACTOR

To the Editor:—*Has the possible role of the cigarette lighter as a cause of lung cancer been considered? The lighter may be suspected in view of the facts that cigarettes appear to be blamed more than pipes or cigars and that fumes from the lighter and its fuels might not be trapped in a cigarette. Cigar and pipe smokers may use mechanical lighters too, but not as often. One pack of cigarettes a day would mean 20 lights. Could such fumes cause lung cancer?*

N. F. Slomer, M.D., Cincinnati.

Answer.—It is reasonable to assume that fumes of a cigarette lighter may be a factor in the etiology of lung cancer in a way similar to that of atmospheric deposit and smoke. However, other factors are apparently more significant. For example, in England, where the death rate from lung cancer is higher than in any other country, the cigarette lighter is probably not nearly as widely used for economic reasons as in the United States. In an excellent study of the relationship of cancer to atmospheric deposit and smoke (*Brit. M. J.* 1:74, 1959), Stocks points out that, although there is a much higher incidence of lung cancer and bronchitis in urban as compared to rural areas in England, there was no urban excess for heavy cigarette smokers. According to Doll (*Brit. M. J.* 1:322, 1959), there is a distinct relationship in 16 countries between the reported cigarette consumption in 1930 and lung cancer death rates in 1952 to 1954. A striking exception is the United States, which had a relatively high cigarette consumption but a relatively low incidence of cancer of the lung, in spite of the popularity of the cigarette lighter in this country. A possibly significant additional factor is that the average pipe or cigar smoker is much less likely to inhale the smoke.

POISONOUS MUSHROOMS

To the Editor:—*Is it true that the poisonous mushroom, Amanita phalloides, is not found in North America?*

A. L. Springer, M.D., Philadelphia.

Answer.—Amanita phalloides has been reported growing in most sections of the United States but is most commonly found in the northeastern part of the country. Many cases of poisoning from this species have been reported in the United States, but, because of problems of identification, some poisonings attributed to this species may have been caused by other species of Amanita (Amanita verna or Amanita brunnescens) which contain the same toxin and produce symptoms similar to those of poisoning by Amanita phalloides.

DIABETES SURVEY IN SCHOOL

To the Editor:—*At a recent medical staff meeting, it was decided to secure information on detecting diabetes in school children. Please give advice as to the value of such a program by urine test.*

G. H. Spurbeck, M.D., Bemidji, Minn.

Answer.—The incidence of juvenile diabetes is low—1 per 2,500 children under the age of 15 years. The most profitable case finding will be among relatives of diabetics. The best procedure to follow would be postprandial urine tests, then, if positive, postprandial determination of blood sugar level, and, finally, a glucose tolerance test. Early cases have been diagnosed in school surveys, and it is advantageous to recognize these persons in the preclinical period. Glycosuria not due to diabetes is extremely common in children and many tests may be performed which would be insignificant, but a single case diagnosed early is worth the effort.

LEPTOTHRIX AND STREPTOTHRIX CULTURE

To the Editor:—*A boy has leptotrichosis of the conjunctiva (Parinaud's conjunctivitis) believed to be due to a Leptothrix. The pathologist has been unable to culture it. A consultant has stated that there is a special technique for cultures and smears to demonstrate the organism, but he is not familiar with it. Another patient has a corneal ulcer believed to be due to a fungus, and, again, the organism has not been demonstrable but it is thought to be a Streptothrix. Please give instructions on how to demonstrate these organisms by smear, biopsy, or culture. What is the treatment, if any, and how effective is it?*

C. T. McCoy, M.D., Hutchinson, Kan.

Answer.—Streptothrix and Leptothrix organisms are best isolated from the eye by the removal of concretions in the lacrimal sac or canaliculae. Corneal lesions should be scraped. The Streptothrix is anaerobic and may be grown on peptone glyc-

---

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any medical or other organization unless specifically so stated in the reply. Anonymous communications cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

erine agar (Breed and others, Bergey's Manual of Determinative Bacteriology, ed. 7, Baltimore, Williams & Wilkins Company, 1957). If biopsy is possible, the lesion will consist of loose granulation tissue composed of epithelioid, lymphoid, and polymorphonuclear cells with many giant cells, among which are scattered necrotic areas containing the organisms. Streptothrix is a filamentous fungus with branching ends as distinguished from the Leptothrix, which is unbranched. Streptothrix is also gram-positive and turns blue in the presence of Gram's stain. The organism responds somewhat to sulfonamides, penicillin, thymol in a 1:1,000 solution given locally, and iodides given locally and by mouth. Leptothrix is rather difficult to isolate. Culture may be accomplished on dextrose-serum-agar with rigid attention to the partial oxygen tensions (Verhoeff and King, *Arch. Ophth.* 9:701, 1933). Treatment is the same as for Streptothrix.

FOOD ADDITIVE

To the Editor:—*Dream Whip, a General Foods product, contains "propylene glycol monostearate." Are there any toxic effects from this chemical when added to food?*

Solomon Goodman, M.D., Brooklyn, N. Y.

Answer.—This consultant is unaware of any toxic effects to be expected from the ingestion of this product. Use of propylene glycol monostearate is permitted by the Federal Food and Drug Administration. Records do not indicate it may be harmful. Detailed information regarding it can be obtained from the Food Protection Committee, Food and Nutrition Board, National Research Council, 2101 Constitution Ave., Washington 25, D. C.

ERGOTISM WITH MIGRAINE

To the Editor:—*A patient who received ergotamine tartrate injections and ergotamine-caffeine suppositories for migraine headaches that occur every other day developed circulatory symptoms of ergotism in one leg. Is there any other appropriate treatment? Is there some way of combating the ergotism? The patient is also receiving psychoanalytic treatment.*

Ralph M. Crowley, M.D., New York.

Answer.—Ergot and its alkaloids are the sovereign treatment of actual migraine attacks. However, caution should be exercised in the use of ergotamine in any form. A patient who has migraine attacks every other day and receives the treatment described probably will develop symptoms of ergotism sooner or later. Long-term administration of the drug may often produce central symptoms, with headaches and giddiness, in addition to peripheral symptoms of ergotism. Instead of the ergotamine, dihydroergotamine could be tried with this patient. It is less toxic but somewhat less effective in combating the actual migraine attack. Therefore, its dose should be about twice that of the ergotamine. If the patient has already developed symptoms of ergotism, ergot and its alkaloids are definitely contraindicated and their administration should be stopped. If the symptoms of ergotism do not disappear after this, vasodilators, such as choline esters, nitrites, papaverin, and cyclandelate, in 100-to-200-mg. doses, should be tried to correct the peripheral effects. Large doses (100-500 mg.) of nicotinic acid, which is a potent peripheral vasodilator, should be useful. Instead of the ergotamines, 30-to-60-minute inhalations of 100% oxygen, which the patient could administer to herself while in bed, should be tried. Some of the newer analgesics, such as dextro propoxyphene hydrochloride, in a dosage of 65 mg. four times daily, may be useful in combating the pain connected with the migraine attacks. Because the patient suffers from migraine attacks every other day, reexamination and reevaluation of the migraine should be attempted. The migraine attacks themselves might be psychogenic due to frustration or might be a symptom of allergy. If they are due to allergy, proper desensitization should be tried. If the attacks are purely psychogenic, the psychoanalytical procedure itself may aggravate the condition. If this should prove to be the case, then use of the abreactive technique with sodium amytal or ether should be tried. If the patient reacts to the abreactive technique with a benign catharsis, the psychoanalytic procedure may be resumed later if desired.

GASTROINTESTINAL CHANGES IN MALNUTRITION

To the Editor:—*What x-ray characteristics are found in the gastrointestinal tract in patients with malnutrition, avitaminosis, and starvation?*

N. B. Jaffe, M.D., Bridgeport, Conn.

Answer.—The question refers to conditions now generally grouped together as the "malabsorption syndrome" (Combined Staff Clinic, *Am. J. Med.* 15:790, 1953). These conditions in some patients produce, or at least are associated with, a disorder of motor function in the small intestine manifested by hypotonicity and slow transit time. If a barium-water suspension is used, flocculation or "clumping" of the barium may occur. If nonflocculating barium preparations are used, the caliber of the lumen may be wider and progress of the opaque material may be slower than average but normal limits are difficult to define. Emptying of the stomach may be slow because of inadequate peristalsis. Evidence has been produced that these disorders of motor function are based on inadequate production of acetylcholine in the tunica muscularis. In advanced cases, both the mucosa and the muscle coat may be found atrophic at autopsy. In uncommon instances, the mucosal folds of the jejunum (valvulae conniventes), as shown on barium examination, may be reduced in number or in height or may be obliterated, leaving the inner surface of the intestine smooth. With proper treatment these motor disorders disappear, but they are irreversible in some advanced cases.

Disturbances in motor function of the intestine, similar to those found with milder nutritional disorders, have been seen in patients who are emotionally disturbed. In advanced nutritional disorders, gas distention of the intestine may simulate ileus. This has been described in sprue. It occurs in southern India among poor persons whose diet consists largely of a preparation of millet, and it may be fatal if dietary treatment is delayed. In the United States, cases of gas distention have been reported in which ileus was simulated and in which the disorder responded to vitamin treatment (Leithauser, *Surg. Gynec. & Obst.* 86:543, 1948). Vitamin insufficiency may play a part in some cases of postoperative distention and paralytic ileus (Frazer and others, *J. A. M. A.* 169:1047-1051 [March 7] 1959). Hypoproteinemia and hypokalemia may cause gas distention which is promptly relieved when blood protein and potassium levels are restored to normal.

Variability of the effects on the intestine seems to depend in part on the severity and duration of the nutritional disorder and on the kind and amount of dietary treatment in the past. However, at present some of the vagaries in the manifestations of nutritional disorders in different persons cannot be explained. Starvation presumably refers to acute deprivation of food. No x-ray studies of such persons have been reported.

FAT AND LEAN FISH

To the Editor:—*Please give a list of fat and a list of lean fish.*

E. M. Meek, M.D., Greenwood, Miss.

Answer.—Fat content of fish may vary from less than 1% to more than 12%. The amount of fat in all fish varies somewhat with the season of the year, with the time of spawning, and with changes in feeding conditions. The table, from the book "Nutrition in Health and Disease," by Cooper and others (Philadelphia, J. B. Lippincott Company, 1953), lists the two categories.

Fat Content of Fish, Percentage

Fish Low in Fat		Fish High in Fat	
Bass	2	Bonito	7
Cod	Trace	Herring	13
Flounder	1	Mackerel	12
Haddock	Trace	Salmon, Pacific	17
Pike	1	Shad	10
Trout, brook	2	Whitefish	7

BIFOCALS IN CHILDREN

To the Editor:—*Bifocal lenses are being prescribed for teen-agers and younger children. What are the reasons for prescribing bifocal lenses other than loss of accommodation?*

H. B. Jenkins, M.D., Chandler, Okla.

Answer.—Bifocal lenses are useful in management of the following ocular problems in children: 1. Paralysis of accommodation. This may occur after diphtheria and measles with encephalitis or in children with brain damage. 2. Motor imbalance. The child with an esotropia which is greater at a distant focus than at near focus might be greatly helped by bifocals. Accommodative spasm resulting in an intermittent esotropia will also be helped. 3. Subnormal vision. The child with subnormal vision may use bifocal lenses to provide magnification for near vision. Bifocal lenses in children play an important part in the management of ophthalmological problems. Their acceptance by parents, teachers, and other children should be encouraged by all physicians.

SEA WATER BY RECTUM

To the Editor:—*Is it theoretically possible to maintain the water requirements of the body by instilling ocean water into the rectum? Are there any records of this having been done in an emergency, such as shipwreck, with absence of potable water, in the otherwise healthy adult?*

M.D., Georgia.

Answer.—The question is aptly answered by Critchley in his book entitled "Shipwreck Survivors" (London, J. & A. Churchill, Ltd., 1943, p. 96): "From time to time the suggestion is made that thirst might be relieved and dehydration prevented by the instillation of salt-water into the rectum. A short note in the medical press during the last war suggested that a Higginson's syringe should be part of a lifeboat's equipment. On theoretical grounds, such a practice would appear to be very undesirable, with great risk of producing purgation and increased dehydration. Allison and Critchley instilled sea water per rectum on six occasions in two cases of diabetes insipidus. Thirst was not relieved and in one subject considerable discomfort was produced. Recently Foy, Altmann and Kondi carried out similar experiments on healthy volunteers who were taking no water by mouth; they found that although sea water is absorbed from the rectum, it does not relieve the objective signs of dehydration and haemo-concentration. They found that the subjects who had sea-water enemas lost more weight than those who were simply starved of water. The chlorides, too, rose higher and they thought there was a risk of harm in bringing about still higher grades of tissue dehydration."

SUBCUTANEOUS ADMINISTRATION OF DEXTROSE SOLUTION

To the Editor:—*Is the subcutaneous administration of hypertonic (10%) dextrose solution justified and, if not, why not? Dextrose in distilled water or isotonic sodium chloride solution has been given subcutaneously with hyaluronidase as a diffusing agent when venoclysis was difficult or impossible, and no local or systemic ill effects have been observed.*

L. A. O'Donnell, M.D., Wichita, Kan.

Answer.—There is little to indicate that the subcutaneous administration of hypertonic (10%) dextrose in isotonic sodium chloride solution would do any harm. However, whether it is as easily absorbed as a 5% solution, which is isotonic, is debatable. The subcutaneous injection of hypertonic solutions of dextrose involves its absorption, balance of water, inorganic constituents of the body fluids, and the state of nutrition. There are situations in which a 10% solution of dextrose seems to be optimal, but, under usual considerations, use of a 5% solution would be preferred.

CORNSTARCH INHALATION

To the Editor:—*A man, aged 32, works in a printing shop where cornstarch powder is blown onto each freshly printed sheet. Because of severe cough, twice in the past year he has had bronchoscopic study which has revealed thick mucus in the lower bronchi. Microscopic examination of the washings shows no eosinophils, cells, or pathogenic organisms. All other laboratory reports are normal. Bronchograms are normal. Is the cornstarch responsible for the cough?*

G. H. Nadeau, M.D., Riegelsville, Pa.

Answer.—It is doubtful that the cornstarch powder is responsible for the condition described. Cornstarch powder is a bland material and is not in itself irritating. The quantity involved is not enough to cause any chronic irritation or be likely on inhalation to reach deeper pulmonary surfaces. The possibility might well be investigated that some other substance capable of producing an allergic reaction and subsequent severe cough is a factor in this case.

DIVERTICULOSIS

To the Editor:—*Please give information, particularly experimental data, as to the pathogenesis of diverticulosis of the gastrointestinal tract.*

Alan A. Kane, M.D., Brooklyn, N. Y.

Answer.—A discussion of the pathogenesis of diverticulosis of the gastrointestinal tract is beyond the necessary space limitations of this department. Most of the data available is derived from anatomic observations only; this consultant is familiar with no experimental work on the subject. The inquirer is referred to the article by Welch (*DM*, June, 1958), which gives a complete discussion of the subject.

WITHDRAWAL OF ADRENAL STEROIDS

To the Editor:—*About one year ago, a 38-year-old woman with scleroderma was given three tapered courses of prednisone therapy lasting four to six weeks with rest periods between. The total duration of treatment was six months, and the total prednisone dosage administered was about 400 tablets of 5 mg. each. Potassium chloride and meprobamate were given in conjunction with the prednisone. The only side-effects encountered during the treatment consisted of slight moon face, hirsutism, spindle legs, potbelly, scant menses, palpitation, and emotional lability. After prednisone therapy was withdrawn completely, the following symptoms persisted: restlessness, emotional lability, memory deficit, anorexia, asthenia, fatigue, and palpitation; stress symptoms, with the slightest exertion followed by palpitation, dyspnea, and perspiration alleviated only by rest (the patient feels best in the morning but is completely exhausted after being up and about for two hours, and she has to rest in bed three times during the day); and pseudorheumatism with tenderness of muscles and bones (sternum, heels, and skin over most bony prominences) improved by rest and aggravated by activity.*

It is now six months since steroid therapy was stopped. The original moon face, hirsutism, and thinning of leg muscles are now absent. Menses alternate between scant and heavy and are regular. The patient has taken meprobamate alone for the past six months and requires 800 mg. four times daily to control the emotional lability, palpitation, and tenderness of muscles and bony surfaces. Her appetite is good, and improvement has been gradual but slow. She is still totally incapacitated as far as productive employment is concerned and is confined to her home. Consultants in internal medicine advise no specific treatment and have indicated that, usually, in six months spontaneous return of adenopituitary function occurs. The six months have passed. How much longer are the present symptoms likely to continue to an incapacitating degree? Is any specific corrective or substitution treatment indicated?

M.D., California.

Answer.—One wonders if the symptoms which persist six months after termination of steroid therapy are actually related to depression of pituitary and adrenal function. This seems unlikely, in view of the fact that there is usually good recovery of this function after six months or less, particularly if the therapy with steroid hormones was intermittent, as in this case. Furthermore, relief of some of the symptoms with meprobamate suggests that emotional factors may be playing an important role. An evaluation of adrenocortical function could be made by means of estimations of the urinary 17-ketosteroid and corticosteroid and the plasma corticosteroid levels, if facilities for the latter determination are available. It should be remembered that not much significance should be attached to a low excretion of 17-ketosteroids in a chronically ill patient. In any event, no specific treatment from the standpoint of the pituitary or adrenals seems indicated. Further treatment with steroids is probably not desirable, as this would only prolong suppression of adrenocortical function if this were currently a problem. Likewise, adrenal stimulation with ACTH has little value in this sort of situation. As a general rule, only the passage of time will permit recovery of normal pituitary and adrenal function after prolonged suppression by steroids, and replacement therapy is usually not indicated except in stressful situations, such as surgical operation, trauma, or febrile illness.

OILY SKIN

To THE EDITOR:—*Is there a direct relationship between the lipid and the cholesterol content of the blood and the oiliness noted on the skin? Is oily skin inherited?*

M.D., Tennessee.

ANSWER.—There is no evidence of any direct relationship between lipid and/or cholesterol contents of the blood and oiliness of the skin. Excessive oiliness of the skin, such as observed in seborrhea oleosa, apparently has an intrinsic, largely endocrine and familial basis.

TREATMENT OF FLAT FOOT

To THE EDITOR:—*Please give information on methods of treatment for flat foot. What kind of arches and shoes should be prescribed? Please suggest some references.*

Donald R. Gibbs, M.D., Cortland, N. Y.

ANSWER.—The problem of flat foot is not simple. The causes are manifold and may be congenital or acquired. It may occur after infection, injury, or paralysis. The most common form is the so-called static flat foot. This is the result of foot strain. The foot is decompensated. This means the work demanded of the foot is greater than the strength of the foot. Thus, lack of exercise, such as normal walking, can be a causative factor. At the same time, prolonged standing can be a factor. Ill-fitting shoes that interfere with normal functions are an important factor. There are many other factors, all of which would have to be taken into consideration in the treatment.

Flat foot is the result of alterations in the relationship of the bones to each other. The heel goes into valgus and the mid-position of the foot is pronated, thus lowering the longitudinal arch. Correction requires elimination of the causative factors. It is necessary to bring the heel into varus and correct pronation of the foot, thus restoring its normal position. With the foot in proper position, normal function must then be reestablished. A technique for doing this is described in "Diseases of the Foot," by Hauser (Philadelphia, W. B. Saunders Company, 1950). Another method is described in "Functional Disorders of the Foot: Diagnosis and Treatment," by Dickson and Dively (ed. 3, Philadelphia, J. B. Lippincott Company, 1953).

ROENTGEN EPILATION

To THE EDITOR:—*Is roentgen epilation of the scalp justified in patients with ringworm which fails to respond to any other form of therapy? Have there been any long-term comprehensive follow-up studies in such cases?*

John B. Light, M.D., Lebanon, Pa.

ANSWER.—The usual epilating dose of x-ray does no known damage to the growing hair follicles. Provided the scalp is subjected to no more than the minimal effective threshold dose, there should be no undue concern about permanent latent epilation, blanching of the hair, or other damage. This consultant knows of no follow-up studies on effects of radiation to the scalp. If the dose is kept within proper limits, there should be no latent effects.

YOGHURT

To THE EDITOR:—*What bacteria are found in yoghurt? Is anything known about the bacteriology of a culture of yoghurt that supposedly came from a Canadian monastery which is reported to be the source used by most American dairies?*

M.D., Oregon.

ANSWER.—The characteristic organism of yoghurt is Lactobacillus bulgaricus, although others may be present. Variations in flavor of yoghurts from different sources are due in part to the presence of different micro-organisms. L. bulgaricus was isolated by Grigoroff in 1905 from Bulgarian fermented milk. Metchnikoff suggested that this organism would be a valuable addition to the intestinal flora, but, according to Jordan and Burrows (Textbook of Bacteriology, ed. 14, Philadelphia, W. B. Saunders Company, 1945, p. 484), it does not become implanted in the intestine. This consultant has no information concerning the yoghurt supposed to have come from a Canadian monastery. The nutritive value of yoghurt is almost the same as that of the milk from which it is made. No unique nutritional or therapeutic properties are known that can be attributed to it.

Government Employees' Health Insurance . .
Further Hearings on Problems of Aged . .

FORAND BILL PROSPECTS

The controversial Forand bill to add health care for the elderly to the Social Security system may not be acted on by Congress this year. After the House Ways and Means Committee ended five days of hearings on the measure in July, supporters of the bill said they did not expect action until next year. Sponsor of the legislation, Rep. Aime Forand (D., R. I.), said, "in view of the heavy agenda of the committee, I don't think we will be able to get this legislation to the floor before adjournment this session."

The administration, the American Medical Association, and numerous other organizations have urged the lawmakers to reject the bill on the grounds that the problem is being solved on the local level, that the bill would lead eventually to complete federal control of medicine in this country, and that it would cancel the progress made so far through private, voluntary means.

Representative Forand said after the sessions that he realized the hearings on the subject were not conclusive and that he was open to any alternative proposal that would work. He suggested that the subject of health care for the elderly be reviewed thoroughly, perhaps by a special subcommittee that would hear from all interested groups.

One of the final witnesses was Dr. R. B. Robins, a member of the Board of Trustees of the American Medical Association. He testified on behalf of the American Academy of General Practice. He declared that the Forand measure is compulsory national health insurance on a limited scale. If it became law, he testified, compulsory national health insurance for everyone could soon result.

Dr. Robins described the quality of medical care he found in England on a recent trip. He said that in his opinion the quality has obviously deteriorated, with long queues of patients waiting for hours to see physicians. Medicine in England, he said, is practiced on an assembly-line basis and is a cold, impersonal process. Physicians there are dissatisfied and are leaving the country, said Dr. Robins.

Another witness, E. J. Faulkner, testifying on behalf of the Health Insurance Association of America, said that addition of health care benefits to federal old age and survivors disability insurance benefits "would retard the rapid progress of voluntary health insurance and impose an increasingly heavy tax burden on workers and employers."

The cost of the program, he said, would be enormous—ranging from 2 billion dollars for the first year to 7 billion dollars by 1980. Eventually old-age tax deductions would amount to between 10 and 15% of payrolls, Faulkner testified.

Dr. F. J. L. Blasingame, executive vice-president of the A. M. A., said after the hearings that "the medical profession welcomed the opportunity to demonstrate to Congress that, although things are not perfect, much progress has been made in meeting the health care needs of the aged without intervention by the federal government.

"It was shown that it would be most unfortunate for the federal government to move in for political reasons and attempt in a compulsory fashion to solve by legislation problems which are being thoughtfully considered at the state and local levels by the medical profession and other dedicated members of the health team.

"Spokesmen for state medical societies, in testimony and statements for the record, reported encouraging progress. It added up to a creditable record.

"If government intervention, along the lines of the Forand bill, should occur, it would result, unfortunately, in the end of many of these voluntary programs."

A. M. A. URGES NURSING-HOME PROGRAM

The American Medical Association asked Congress to approve an insured loan program for proprietary nursing homes as part of any over-all housing measure before the lawmakers.

In a letter to a Senate banking subcommittee, which is starting a new round of sessions on housing legislation, Dr. F. J. L. Blasingame, A. M. A. executive Vice-president, said the A. M. A. actively supported the nursing-home provision [illegible] atch-all housing bill vetoed by [illegible] earlier this year.

"We believe there is a critical need for new and improved facilities tailored to the specific health requirements of older citizens," said Dr. Blasingame in a letter to subcommittee chairman John Sparkman (D., Ala.). The American Nursing Home Association and other organizations, he said, "have accumulated evidence over recent years showing that they cannot provide service of the desired quality or quantity, because they are unable to obtain the credit they need on reasonable terms to permit them to increase the number and size of adequate nursing-home facilities."

The provision would authorize guarantees by the Federal Housing Administration of loans for construction or improvement of proprietary nursing homes. Dr. Blasingame declared that there is an immediate need for such guarantees for proprietary homes, "since according to the latest statistics over 70% of nursing-home patients are cared for in such facilities."

The A. M. A. official also proposed eliminating a requirement in the previous housing bill that state Hill-Burton authorities decide whether there is a need for the guarantees. The program should be administered by the FHA, and it should be sufficient that the homes meet standards established by the state, he said.

INTERNATIONAL HEALTH MEASURE BACKED

A House commerce subcommittee launched hearings on the Senate-passed bill establishing a 50-million-dollar international medical research program. Witnesses at the first round of hearings urged congressional approval of the measure, not only to spur medical knowledge but to improve international relations.

The administration's views were scheduled to be presented at a second series of hearings starting early in August. Arthur S. Flemming, Secretary of Health, Education, and Welfare, has opposed some provisions of the measure, including the flat 50-million-dollar yearly authorization.

One of the first witnesses, Dr. Howard A. Rusk, executive vice-chairman of Committee on Health for Peace, told the subcommittee, headed by Rep. Kenneth Roberts (D., Ala.), that the first-year cost for the research program would probably be only 10 or 15 million dollars. He noted that the fiscal year has already started and there would not be time to get the program into full operation for the entire year, even of Congress clears the bill this session.

Also supporting the bill were Gen. Omar N. Bradley, chairman of the Committee on Health for Peace, and Major Gen. Melvin J. Maas, chairman of the President's Committee on Employment of the Physically Handicapped.

General Bradley said the legislation would make it possible for the United States to support and coordinate medical research in foreign countries which could result in "pay-off" answers to killing diseases like cancer and heart disease.

In a statement to the subcommittee the American Medical Association reiterated its support of the measure.

HEALTH INSURANCE FOR GOVERNMENT WORKERS

The Senate overwhelmingly approved, by a vote of 81 to 4, a program of voluntary health insurance for United States employees. The House Post Office and Civil Service Committee immediately slated hearings on the legislation.

The twin actions enhanced prospects for passage of the measure this year. Despite administration opposition to some features of the Senate-passed bill, most Senate Republicans joined with the Democrats in voting for it.

The American Medical Association renewed its support of the principle of the legislation in a statement submitted to the House committee headed by Rep. Tom Murray (D., Tenn.). Dr. F. J. L. Blasingame, A. M. A. executive Vice-president, said the organization continues to endorse legislation which would authorize the Civil Service Commission to make available on a voluntary contributory basis group hospital, surgical, medical, and other personal health benefits for civilian officers and employees in the federal service.

The measure before the committee, he said, meets most of the suggested standards for a health insurance program drawn up by the A. M. A. Council on Medical Service and the Council on Legislative Activities.

Dr. Blasingame proposed two amendments which "can be made rather easily within the framework of this legislation." One would provide coverage on a voluntary, contributory basis for government workers who have already retired, and the other would eliminate a requirement that there be "one government-wide service benefit plan." Dr. Blasingame said, "we feel that the phrase 'one government-wide,' while intended to eliminate the necessity of the Civil Service Commission's entering into contracts with individual service benefit plans, is unfortunate.

"We know of no nationwide service benefit program which could meet the requirement of providing service to all federal employees. In a number of states, the Blue Shield programs operate indemnity plans."

One of the chief administration objections to the bill is the cost to the government—an estimated 145 million dollars a year, compared with the 105-million-dollar ceiling the administration had proposed.

HEARINGS ON PROBLEMS OF AGED RESUME

Sen. Pat McNamara (D., Mich.) called federal officials and spokesmen for national organizations to a series of hearings before his special Senate labor subcommittee in July and August to describe their activities in the field of aging and present their views and recommendations on needed action.

"The subcommittee will be concerned with such matters as whether present activities and policies are adequate to meet the needs of the aging and aged and the kinds of additional legislative action required," he said.

"There is a wealth of information in the experience and study of many voluntary organizations in this field, and we mean to benefit from their advice and consultation," he declared.

Some of the "top priority" problems the subcommittee will consider, he said, will include housing needs of the elderly, job discrimination, medical care, conditions of nursing homes, measures to prevent physical and mental deterioration, adequate income, and "elements of insuring a productive, meaningful life for those who retire from regular employment."

"If we continue our present practice of relegating older persons to the sidelines," said Senator McNamara, "the financial burden for the country in the way of institutions for the aged will be too fantastic to conceive."

"The time has long passed," he said, "for the country to be able to ignore this great domestic challenge of the midcentury. In the decades to come we should never allow it to be said that Americans—young and old alike—were foolhardy enough to waste the productive contributions of an expanding population of men and women reaching the age of 70 and beyond."

Pro-Banthīne®...what it will do and what it will not do...in Peptic Ulcer

Much consideration has been devoted ecently to a reappraisal of the role of nticholinergic drugs in the management of peptic ulcer.

Such reappraisal has presented no difculties at Searle. At no time have we uggested that Pro-Banthīne should be ubstituted for antacids, rest, psychoherapy or even common sense in manging the patient with peptic ulcer.

Action of Pro-Banthīne:

The action of Pro-Banthīne (brand of propantheline bromide) is simple and its ffects, allowing for the variability of the human estate, are predictable. Pro-Banthīne competes with and, in competing, inhibits the action of acetylcholine. This competition is highly effective at parasympathetic effector sites and, except with high dosage, somewhat less so at the autonomic ganglia.

Since parasympathetic nerves are moor and secretory to the stomach and motor to the intestines, Pro-Banthīne reduces both motility and secretions in the stomach and motility in the intestines. These actions have often been demonstrated experimentally and clinically.

What It Does:

Relieves Pain—One of the natural consequences of the actions of Pro-Banthīne is to reduce or to eliminate pain in peptic ulcer. Whether the pain is attributable to acid, to excessive motility or, to steer a middle course, to spasm induced by acid, the pronounced inhibitory effect of Pro-Banthīne on both secretion and motility might be expected to suppress the characteristic distress of ulcer.

In point of fact, relief of pain is one of the most prominent effects of Pro-Banthīne in peptic ulcer. Phrases such as "unexcelled" and "almost invariably effective" dot the literature referring to it.

Reduces Acidity—Since reduction of acid and rest for the hypermotile stomach and duodenum are accepted means of supporting the regenerative processes of the gastroduodenal mucosa, the physiologic modifications induced by Pro-Banthīne should be expected to have therapeutic implications in the healing of ulcers also. They do. Not only does Pro-Banthīne reduce gastric acid and motility but, through these actions, it also potentiates and prolongs the neutralizing property of antacids.

Aids Healing—Schwartz, Lehman, Ostrove and Seibel prescribed 120 to 180 mg. of Pro-Banthīne daily for 129 ulcer patients and found definite evidence, both clinical and roentgenographic, of accelerated healing.

With high doses (270 to 330 mg. daily) Barowsky, Schwartz and Lister reduced the mean duration of treatment in twenty-five patients with refractory ulcers from 135 to 17 days.

Helps Prevent Recurrences—Much the same considerations argue for the value of Pro-Banthīne in holding the reactivation of healed ulcers in abeyance, but the difficulty of regulating the diet, medication and mode of living of ulcer patients over long periods of time makes assessment of the role of Pro-Banthīne in preventing recurrences difficult. Nevertheless, in a study of 250 patients with established patterns of recurrence Texter and associates found that patients maintained on methantheline, less potent analogue of Pro-Banthīne, had significantly fewer recurrences than a control series taking atropine.

Schwartz and his co-workers considered freedom from symptoms when recurrences would be expected, together with tolerance and relief of symptoms, as a standard in establishing successful treatment in 118 of 129 patients.

Provides Selective Action—In inhibiting the action of acetylcholine in the stomach and intestines Pro-Banthīne also, though to a lesser extent, influences other cholinergically activated organs. That this influence sometimes leads to such secondary effects as dryness of the mouth, blurring of vision and hesitancy of urination is well known and bears consideration. It is one of the distinct advantages of Pro-Banthīne that it acts more effectively on the gastrointestinal tract than elsewhere. Secondary effects usually disappear during the course of treatment and only rarely limit therapy.

Evidence of selective action has been recorded by several investigators, but the most interesting confirmation of this selectivity was reported by Barowsky, Schwartz and Lister. They prescribed 30 to 45 mg. of Pro-Banthīne every hour and a half, except for the hour before and the hour following meals, for their patients with refractory ulcers. They were surprised and gratified by how few anticipated side reactions materialized. No serious toxic effects or side reactions occurred. The incidence of good response on double or triple the usual doses rose from 31 to 88 per cent.

Lowers Incidence of Failures—Variable results might be anticipated in a disease in which the psychic component plays such a large part and, of course, response to treatment does vary in patients with peptic ulcer. Observations of Lichstein and associates show that the 11 per cent of their patients who failed to respond to Pro-Banthīne had deeply ingrained anxiety on a psychoneurotic basis.

Successful management of such patients may well depend more on the patient's intelligence, the modification of his social environment and the skill of his physician in psychotherapy than on any medication. However, the successful experience of Barowsky and his colleagues in using large, frequent doses of Pro-Banthīne in patients with refractory ulcers might be borne in mind before Pro-Banthīne is abandoned as ineffective. Also worthy of trial in these patients is Pro-Banthīne® with Dartal® (brand of propantheline bromide with thiopropazate dihydrochloride), which combines the outstanding anticholinergic action of Pro-Banthīne with the highly efficient tranquilizing action of Dartal.

What It Will Not Do:

There are aspects of the medical management of peptic ulcer in which Pro-Banthīne has no demonstrable benefit. There is no reliable evidence that Pro-Banthīne reduces the incidence of complications or the need for surgery.

It will not abolish the obligation of physicians to evaluate each patient individually and to modify therapeutic measures to each patient's requirements. Nor will it do away with the necessity for the patient to regulate his life to the demands of his disease. But the modifying action of Pro-Banthīne on the physiologic activity of the gastrointestinal tract and its beneficial effects on the course of peptic ulcer have been established by too many investigators to be seriously questioned. Wisely used in conjunction with other standard therapeutic measures, Pro-Banthīne can inhibit pain, hasten healing and space out the intervals of peptic ulcer recurrence and do so without serious discomfort to the patient.

OCULAR SURGERY IN THE AGED

Morris Feldstein, M.D., Abraham L. Kornzweig, M.D.
and
Julius Schneider, M.D., New York

The beneficial results of surgery were weighed against the risks in a review of 118 major eye operations on a series of patients from 65 to 94 years of age. Eighty-five operations were for cataract and 18 for glaucoma. Most patients had some form of circulatory disease, 19 had hernias, 16 had pulmonary emphysema, and 11 had diabetes. Nevertheless, there were only two deaths attributable to the operation. The declining years of many of these patients were immeasurably brightened by restoration of vision, which in some cases meant ability to carry on a reasonably self-sufficient and meaningful existence for many years without being a constant burden to others. Undue emphasis on the risks of operation can lead to the withholding of beneficial ocular surgery in the aged.

OLD AGE presents special problems in major ocular surgery. In order to bring the light of experience to bear on this question, we have reviewed the 118 major eye operations done on the residents of the Home for Aged and Infirm Hebrews of New York over the past 15 years. These persons were all over 65 years of age.

We have studied the types of operations, the preoperative medical status, age at operation, the results of surgery, and the complications which we have encountered, both local and general, and have tried to derive some general principles as to the feasibility of surgery and the risks involved in this age group.

Indications and Contraindications

The indications for ocular surgery were fairly limited in scope. Most of the operations were for restoration of vision which had been lost due to cataract formation. Surgery was also used in cases of glaucoma when medical measures had failed. There were other indications, but these were relatively few in number.

Table 1 lists the number of operations in the different categories. Cataract extractions total 85 cases, or 72%. Operations for glaucoma were done in 18 cases, and there were 4 operations for retinal detachment. The balance, as can be seen from the table, is composed of a small number of different procedures.

From the Department of Ophthalmology, the Home for Aged and Infirm Hebrews of New York, and the Ophthalmology Service, the Mount Sinai Hospital.

The most important contraindication for performance of surgery was the presence of a psychotic state which rendered the patient unmanageable or likely to be unaware of his visual status. A second one was the patient's own lack of desire for surgery despite the presence of a material decrease in vision. However, in such cases if there was any condition likely to cause irreversible damage to the eye, such as the presence of glaucoma or a hypermature cataract, the patient was strongly urged to undergo surgery and usually he followed this advice. Occasionally there were situations where surgery would have been considered except for the presence of another condition which was an active threat to life itself. In such instances the elective surgery of the eye was either postponed or abandoned.

TABLE 1.—*Types of Ocular Surgery Performed on Persons over Sixty-five Years of Age in 118 Cases*

Cataract extraction	85
Intracapsular	68
Extracapsular	17
Discission	4

Enucleation	2
Retinopexy	4
Dacryocystorhinostomy	1
Biopsy of lacrimal gland	1
Tarsorrhaphy	1
Sphincterotomy	1
Dacryocystectomy	1
Total	118

*See table 5.

However, numerous serious medical conditions which coexisted at the time surgery was indicated were considered as deterrents rather than absolute contraindications. These included coronary sclerosis with severe insufficiency, severe diabetes, status after recent myocardial infarction, status after recent cerebrovascular accident, advanced hypertension, and severe asthma. No attempt was made to set up hard and fast rules, since each problem was discussed and evaluated with the medical staff. The complicating conditions and their frequency are listed in table 2. Hypertension of varying degrees was by far the commonest condition encountered at the time of operation. Arteriosclerotic heart disease was present in many patients. Hernias of all types, pulmonary emphysema, peripheral arteriosclerosis, general arteriosclerosis, varicose veins, and hypertrophy of the prostate were also encountered.

Risks Versus Gains

There were limited goals in the operations performed, particularly those concerned with cataract or glaucoma. Each operation was a calculated risk in itself, and oftentimes, in questionable cases, the patient's demands for vision were the deciding factor. The following case is of particular interest in this regard.

An 83-year-old male had bilateral cataracts. However, the medical department was loath to give permission for surgery because he suffered from left-sided heart failure, pulmonary emphysema, hypertension, epidermoid (squamous cell) carcinoma of the vocal cord, chronic cholecystitis, and severe orthopnea, which presented a special problem since cataract operations are usually performed with the patient in the recumbent position. When the patient finally threatened to commit suicide if something were not done to restore his vision, the medical department reluctantly, with the consent of the psychiatric department, agreed to permit the patient to undergo ocular surgery. A combined intracapsular cataract extraction was done on the right eye. The patient was operated on in a semirecumbent position. He was allowed out of bed the day of the operation, being permitted to sit up in a wheel chair. The postoperative course was completely uneventful. His medical condition showed no deterioration as a result of surgery. Within four weeks the patient was fitted with glasses, and his resulting vision was 15/30 in the right eye. Although he lived for only eight months after the operation,

TABLE 2.—*Antecedent General Diseases of Patients Undergoing Eye Surgery*

	No. of Patients
Hypertension	62
Arteriosclerotic heart disease	37
General arteriosclerosis	14
Peripheral arteriosclerosis	16

Asthma	1
Pulmonary atelectasis	2
Epidermoid (squamous cell) carcinoma of vocal cord..	1
Syphilis	1
Amputation, leg	1
Senile schizophrenia	1

those months were immeasurably brightened by his ability to see. All members of our staff agreed that the risks taken in this case were thoroughly justified.

There were other cases with similar considerations in varying degrees. These older persons stand to gain a great deal by the restoration of vision in their declining years in spite of whatever risks may be entailed. This became more apparent as we realized that these risks have frequently been overestimated. It would be well indeed for physicians in general to approach this problem with a fresh viewpoint.

Age Distribution

Most of the operations were done on patients between 75 and 84 years of age (70 patients). The balance of cases was evenly distributed between those in the age groups 65-74 (28 patients) and 85-94 (20 patients). Operative indications were not encountered in anyone over 94 years of age.

Results

The results of the cataract extractions were extremely encouraging (table 3). In 59, or 87%, of 68 intracapsular cataract extractions there was vision of 15/70 or better as a result of operation. Of 17 extracapsular cataract extractions done, 12, or 71%, resulted in vision of 15/70 or better. When both types of procedures are considered together, a total of 71 eyes, or 84%, showed a vision of 15/70 or better. This is sufficient vision to enable the patient to take care of himself.

Table 3.—*Vision After Cataract Extraction in Eighty-five Cases*

Vision	Intracapsular	Extracapsular
15/20	3	...
15/25	8	1
15/30	14	4
15/40	18	6
15/50	8	1
15/70	8	...
15/100	2	...
15/200	7	5
	68	17
15/70 or better	59(87%)	12(71%)

Postoperative vision after cataract extraction is shown in table 4 according to age group. The majority of patients had vision of 15/70 or better in every one of the age groups. Detailed analysis of the cases in which vision was 15/200 or less revealed adequate reason for the poor vision; each patient showed pathological changes which could not be attributed to surgery, except for one case of severe vitreous hemorrhage. It is important to note that in these cases, with the exception of those of optic neuritis and vitreous hemorrhage, all patients had a return of useful peripheral vision after cataract extraction. Their central vision was defective by reason of their particular eye lesions. However, they were usually grateful for the peripheral vision that they obtained as a result of the operation. It is important to appreciate the full value of the vision provided by the retina outside of the macular area. Even though the macula is destroyed, the vision remaining in the rest of the field is sufficient to enable the person to carry on a reasonably self-sufficient and meaningful existence without being a burden to others around him. Therefore, even though visual acuity may be reduced by reason of macular damage, cataract extraction in this older age group is still definitely indicated when cataracts are present together with macular degeneration.

Table 4.—*Vision After Cataract Extraction, by Age Group*

Age Group	15/20	15/25	15/30	15/40	15/50	15/70	15/100	15/200 or Less
65-74		2	6	6	2	2	0	1*
75-84	2	6	10	13	5	6	1	10†
85-94	1	1	2	5	2	0	1	1‡

* Optic neuritis.

† Preoperative senile macular degeneration, 4; old glaucoma, 3; diabetes with macular degeneration, 2; and vitreous hemorrhage, 1.

‡ Diabetic retinitis.

The cases of glaucoma are listed in table 5 according to type of operation and result obtained. Most were controlled either with or without medication after surgery. Two cases were uncontrollable even after surgery and went on to total blindness. In general, we favor the use of iridencleisis and found it reasonably successful in the comparatively few cases of glaucoma that we treated. However, this experience is too small to justify any general conclusions.

Complications

The postoperative complications were few in number, especially in view of the age of our patients (table 6). The complications are divided into two types, general and ocular. In most of the cases there were no general complications. This is of particular interest because of the fears that attend any ocular surgery in this age group, not only in the minds of the patient's family but also in the mind of the attending physician. Many patients had the usual diseases found in this age group, in both number and severity, yet it was extremely gratifying to find that there were relatively few postoperative general complications. Of the 10 patients with general complications, 6 suffered from transient postoperative psychosis. In more recent experience this complication has largely been eliminated be-

Table 5.—*Results of Treatment of Glaucoma in Eighteen Patients*

Cyclodiathermy	3	...	2	1

At the time of this writing, four weeks after the anaphylactic reaction, the patient is up and about, his blood pressure and pulse rate are normal, and his cardiovascular findings are quite satisfactory. He remains disoriented as to time and place, and this is perhaps best explained by the cerebral injury due to anoxia during the severe cardiovascular collapse in an elderly arteriosclerotic person. There is no paralysis.

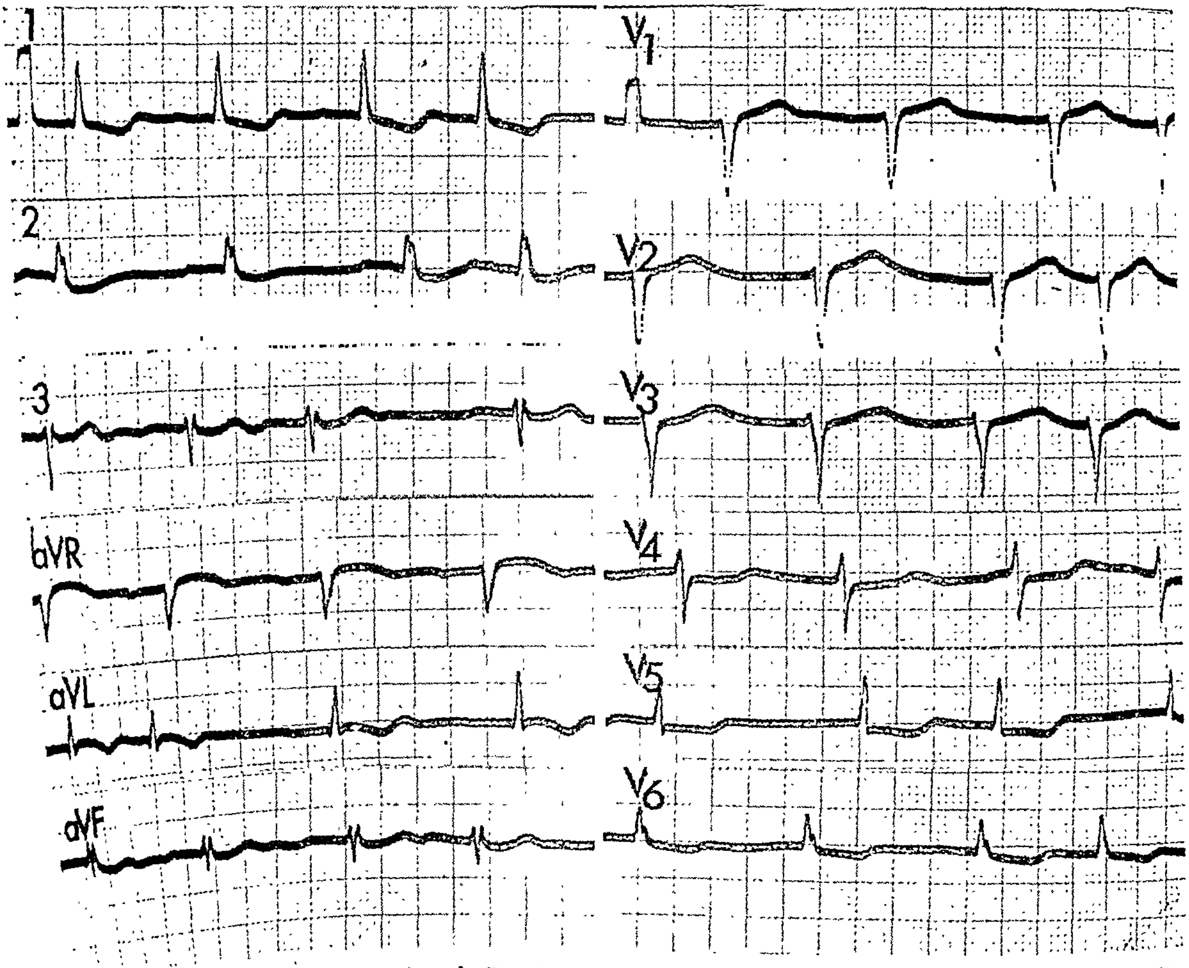

Fig. 2.—Electrocardiogram taken approximately 50 minutes after that in figure 1. Auricular fibrillation has changed to sinus mechanism, and occasional auricular premature contraction is present. The P-R interval is prolonged to 0.24 seconds. There is evidence of left ventricular strain and insufficient coronary circulation. Intraventricular conduction disturbance, as well as injury pattern, has disappeared.

SIMPLE BEDSIDE TEST OF RESPIRATORY FUNCTION

Thomas H. Snider, M.D., John P. Stevens, M.D., Freeman M. Wilner, M.D.
and
Benjamin M. Lewis, M.D., Dearborn, Mich.

The ability of a patient to blow out a match at a distance of 6 in. (15 cm.) was found to be a useful clinical test if conditions were duly standardized. This ability was tested in 126 patients and shown to be well correlated with the results of two other tests of respiratory function, namely, the tests for one-second vital capacity and maximum breathing capacity. The match test is feasible as a bedside procedure for detecting signs of airway obstruction. If it gives positive results, more specific tests for pulmonary function should be performed.

The bedside signs of obstruction to air flow, such as wheezes and prolonged expiration, do not give the quantitative information needed to properly evaluate respiratory function. Two quantitative tests for airway obstruction in common use today, determination of the maximum breathing capacity[1] and determination of the timed vital capacity,[2] require special equipment not available at the bedside. In this report a simple, semiquantitative, bedside test for airway obstruction is evaluated.

The inability to blow out a match held near the open mouth depends on the velocity of air flow and thus may be affected by airway obstruction. We have standardized this procedure and in this report correlate the ability to blow out a match with the maximum breathing capacity and with the one-second timed vital capacity in 126 patients with various forms of pulmonary disease.

Method

Standard book matches are used. After the initial flare, when the match is burning steadily, it is held 6 in. from the patient's open mouth. The patient is first instructed to inspire maximally and then expire rapidly in an attempt to extinguish the burning match. It is important that the patient not purse his lips, for he must expire with his mouth completely open to measure true air-flow velocity. This procedure is repeated several times to assure maximal effort on the part of the patient. All patients tested in this study performed the timed (one-second) vital capacity (with use of the Gaensler-Collins Vitalometer) and maximum breathing capacity[3] tests, and results of these tests were correlated with those of the match test.

Results

A total of 126 patients were tested. Seventy-four were able to extinguish the match, using the method described, while 52 could not. The mean value of the one-second vital capacity for those who could not blow out the match was 0.97 liter with a standard deviation of ± 0.47 liter. For those who could extinguish the match the mean value for the one-second vital capacity was 2.49 liters with a standard deviation of ± 0.57 liter. Eighty-five per cent of the 52 patients who could not blow out the match had a one-second vital capacity below 1.60 liters, while 85% of the 74 patients who could blow out the match had a one-second vital capacity greater than 1.60 liters.

The 52 who could not blow out the match had an average maximum breathing capacity of 40.7 liters per minute with a standard deviation of ± 16.53 liters per minute. The 74 who could blow out the match had an average maximum breathing capacity of 93.0 liters per minute with a standard deviation of ± 25.85 liters per minute. Eighty per cent of the 52 who could not blow out the match had a maximum breathing capacity below 60 liters per minute, while 80% of the 74 who could extinguish the match had a maximum breathing capacity above 60 liters per minute (fig. 1 and 2).

The match test appears to be a fairly reliable semiquantitative guide to airway obstruction. It may fail to differentiate, however, certain patients with a greatly reduced total vital capacity due to pulmonary fibrosis and other conditions limiting expansion of the lungs from patients with airway obstruction. This is because the one-second vital capacity may be a normal percentage of the reduced total vital capacity but still inadequate to extinguish the match. The normal patient with a total vital capacity of 4,000 cc. usually exhales at least 3,200 cc. of this in the first second and, since this exceeds 1,600 cc., is able to extinguish the match. The patient with obstructive emphysema with a total vital capacity of 3,000 cc. cannot blow out the match, for it takes him over one second to exhale 1,600 cc. Results in two patients with restrictive pulmonary disease due to pulmonary fibrosis

cause only one eye is covered after operation. In previous years, when both eyes were usually covered after surgery, postoperative psychosis was more apt to occur. In this connection, it is worthwhile describing the following experience.

A 73-year-old female had only one functioning eye, and this eye had a mature cataract. A combined intracapsular cataract extraction was done and this one eye was dressed, leaving the patient in total darkness. The second day after operation she developed an acute postoperative psychosis. On the third postoperative day the patient was removed from the hospital and taken back to the Home. In addition, the dressing was removed and a plastic shield containing a +10 D. sphere in its center was placed over the eye and taped on securely. Underneath the shield, the eye was open. After transfer, the patient's psychotic condition began to improve, and in 48 hours she was again normal. The eye itself suffered no damage, healing uneventfully. Her final postoperative vision in this eye was 15/40.

TABLE 6.—*Postoperative Complications of Ocular Surgery in 118 Patients*

General	No.
No complications	108
Complications present	10
Myocardial infarction with recovery. Preexisting history of 1 occlusion and anginal syndrome for 2½ yr.	1
Acute postoperative psychoses	6
Pulmonary infarction	1
Death	2
Female, aged 75: postoperative congestive failure with death after 14 days	
Female, aged 83: acute myocardial infarction with death on 2nd day after operation	
Ocular	
No complications	106
Complications present	12
Mild iritis due to lens cortex in anterior chamber after cataract extraction. Recovered	
Postoperative cataract. Choroidal detachment after 8 days. Reattached spontaneously	
Extracapsular cataract extraction. Temporary postoperative glaucoma and iritis	
Postoperative cataract extraction. Iris prolapse. No further surgery. Result good	
Cataract extraction. Vitreous hemorrhage. Slow recovery over period of 3 yr.	
Cataract extraction. Postoperative glaucoma. Controlled with medication (2 patients)	
Cataract extraction. Vitreous loss during operation and postoperative hyphema. Eventual recovery of vision	
Cataract extraction. Postoperative hyphema. Absorbed quickly	
Cataract extraction. Postoperative retinal detachment. Operation successful for retinal detachment	
Cataract extraction. Postoperative corneal dystrophy. Eventual loss of vision	
Cataract extraction. Endophthalmitis. Eventual phthisis bulbi	

The two cases in which death occurred are worthy of special consideration. In one there had been a history of previous myocardial infarction and repeated bouts of cardiac failure over the preceding two years. However, the operation was performed because the patient was completely disabled by her cataracts and personally requested that cataract extraction be done. Death due to myocardial infarction occurred two days postoperatively. One can only wonder whether this death was due to the operation or might not have occurred anyway. The second case, in which congestive heart failure and death occurred 14 days after operation, raises the same question. Since people in this age group are continually suffering incidents of myocardial infarction, pulmonary infarctions, and other emergencies, an occasional complicating incident of such type may be expected to occur coincidentally with surgery. However, even if we attribute these unfortunate sequelae to the surgical intervention, they still constitute an extremely small percentage of the total.

The effect of hypertension requires special comment. This condition was present in 62 of the 118 patients operated on. In spite of this, the incidence of hemorrhage or other complications feared as a result of hypertension was extremely low. Only one vitreous hemorrhage was encountered and one hyphema. This actually is less than the usual percentage encountered in the average published series in younger persons. One should not be fearful, therefore, of hypertension when one is considering the feasibility of ocular surgery.

The ocular complications were few in number. There is a total of 12 such cases, and these are enumerated in table 6. One patient developed mild iritis, presumably due to the presence of lens cortex in the anterior chamber after cataract extraction. There was an uneventful recovery from this. Another patient suffered postoperative choroidal detachment; reattachment occurred spontaneously. Postoperative glaucoma and iritis turned out to be a temporary condition which resolved under medical treatment in one case. A case of postoperative iris prolapse after cataract extraction was merely observed. The patient continued to enjoy good vision and the condition of the eye remained quiet. The case in which vitreous hemorrhage was encountered was of particular interest. The patient's case was followed over a period of three years, during which time there was slow recovery of vision. Eventually vision was 15/40 with correction.

Two cases of glaucoma developing after cataract extraction were controlled with medicaments. Another patient in whom vitreous loss was encountered during operation and development of postoperative hyphema followed had poor vision for several years. However, eventually the vision became 15/50 in this eye with correction, which was a most unexpected result. Another case of cataract extraction with postoperative hyphema was followed by uneventful absorption of the hyphema. A patient with

600,000 units of penicillin the morning of the operation and within a few minutes experienced severe respiratory distress and quickly collapsed. Pulse and blood pressure became unobtainable five minutes after the administration of penicillin, and the patient appeared in extremis. At this time epinephrine, 1 cc., and hydrocortisone sodium succinate (Solu-cortef), 100 mg., were administered intravenously and levarterenol (Levophed), 4 cc. in 500 cc. of dextrose, was given as an intravenous drip.

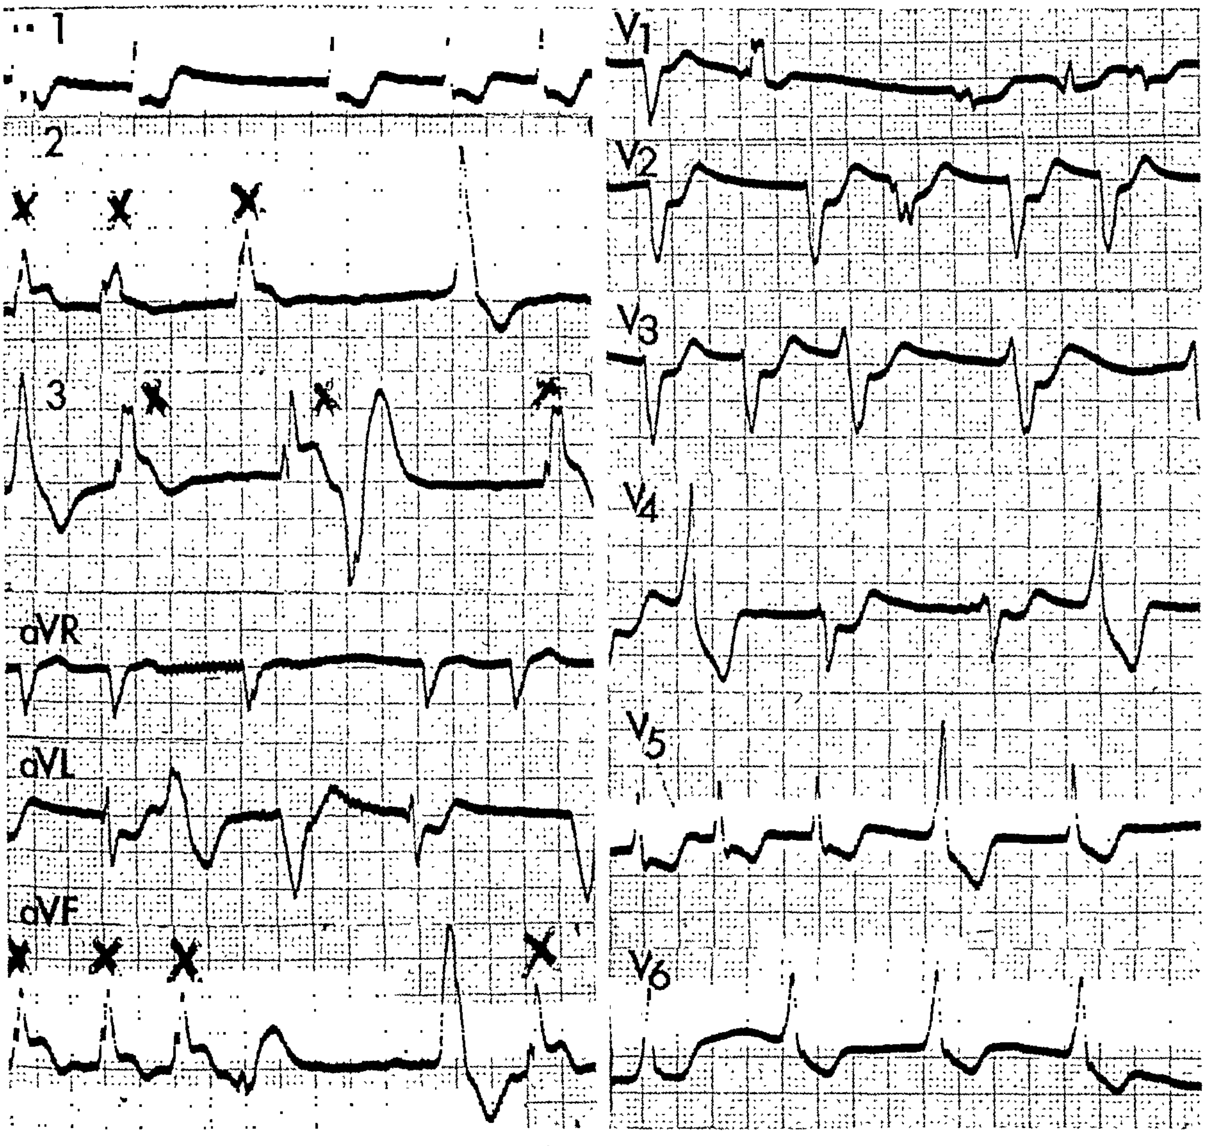

Fig. 1.—Electrocardiogram taken 15 minutes after administration of penicillin, showing auricular fibrillation, multifocal ventricular ectopic beats, and intraventricular conduction disturbance. Findings in leads 2, 3, and aVF (marked X) indicate severe coronary insufficiency and injury in posterior wall of left ventricle.

An electrocardiogram taken 15 minutes after the penicillin administration (fig. 1) and while the patient was in severe shock showed auricular fibrillation, intraventricular conduction disturbance, severe coronary insufficiency, and marked injury to the posterior wall of the left ventricle. A second electrocardiogram (fig. 2), taken approximately 50 minutes after the first, showed a remarkable change toward normal. The patient was regaining consciousness at that time, and a giant urticaria-like eruption became apparent over the entire body. From then on the patient made a complete recovery as far as his cardiovascular system was concerned. A third electrocardiogram was taken about three weeks later. This showed a regular sinus rhythm, with a slightly prolonged P-R interval, left ventricular strain, and insufficient coronary circulation. (No tracing before the occurrence of shock was available for comparison.)

At the time of this writing, four weeks after the anaphylactic reaction, the patient is up and about, his blood pressure and pulse rate are normal, and his cardiovascular findings are quite satisfactory. He remains disoriented as to time and place, and this is perhaps best explained by the cerebral injury due to anoxia during the severe cardiovascular collapse in an elderly arteriosclerotic person. There is no paralysis.

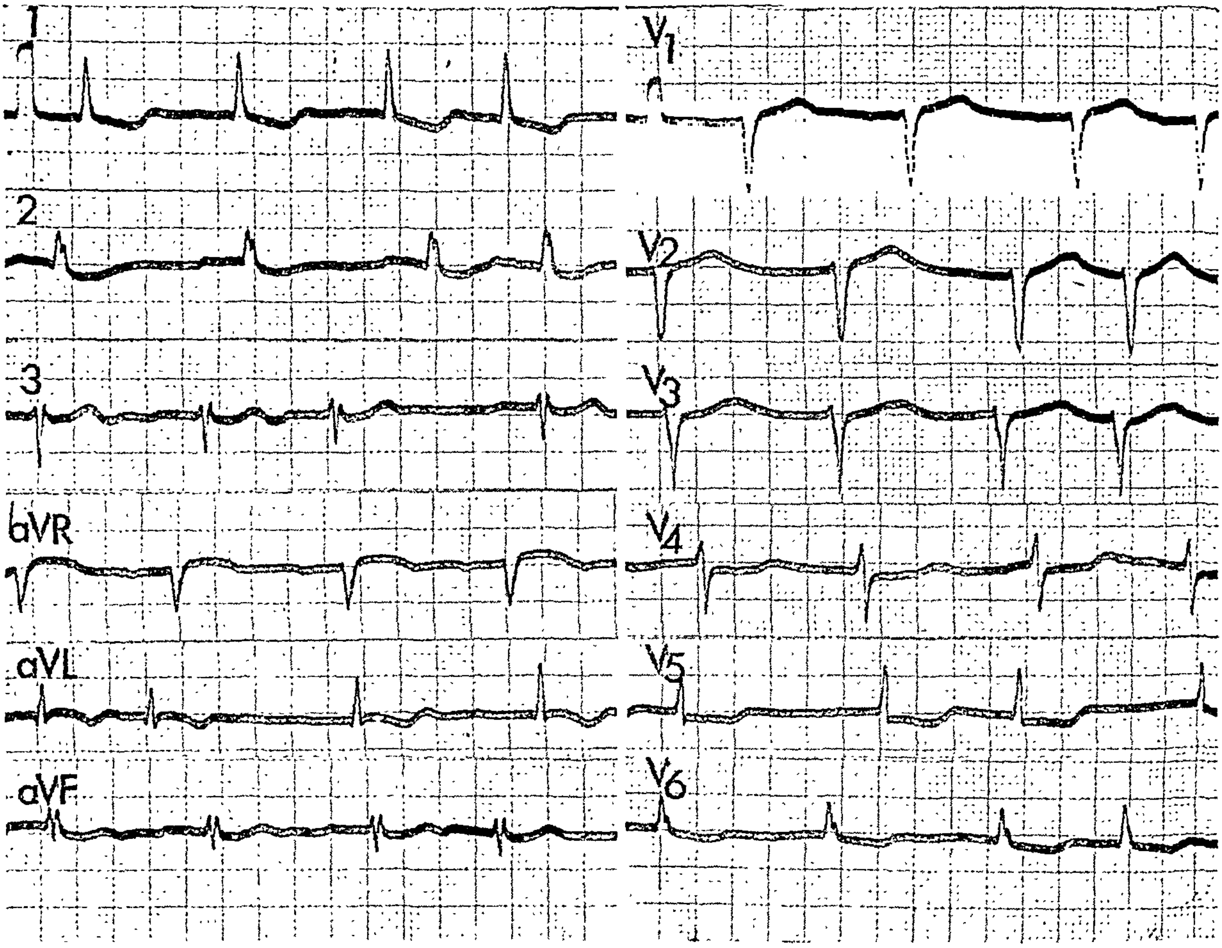

Fig. 2.—Electrocardiogram taken approximately 50 minutes after that in figure 1. Auricular fibrillation has changed to sinus mechanism, and occasional auricular premature contraction is present. The P-R interval is prolonged to 0.24 seconds. There is evidence of left ventricular strain and insufficient coronary circulation. Intraventricular conduction disturbance, as well as injury pattern, has disappeared.

Summary and Conclusion

A case of severe, nearly fatal, anaphylactic reaction to penicillin occurred in an elderly man. An electrocardiogram was taken at the height of the shock and approximately 50 minutes later. The severe electrocardiographic changes were transient. The patient made a complete recovery as far as his cardiovascular system was concerned, but the central nervous system showed less satisfactory recovery. The efficacy of the treatment in promptly reversing the electrocardiographic abnormalities strongly suggests that the myocardium and the coronary circulation are capable of participating directly in anaphylaxis and that sudden death during such reaction may be explained on this basis.

SIMPLE BEDSIDE TEST OF RESPIRATORY FUNCTION

Thomas H. Snider, M.D., John P. Stevens, M.D., Freeman M. Wilner, M.D.
and
Benjamin M. Lewis, M.D., Dearborn, Mich.

The ability of a patient to blow out a match at a distance of 6 in. (15 cm.) was found to be a useful clinical test if conditions were duly standardized. This ability was tested in 126 patients and shown to be well correlated with the results of two other tests of respiratory function, namely, the tests for one-second vital capacity and maximum breathing capacity. The match test is feasible as a bedside procedure for detecting signs of airway obstruction. If it gives positive results, more specific tests for pulmonary function should be performed.

The bedside signs of obstruction to air flow, such as wheezes and prolonged expiration, do not give the quantitative information needed to properly evaluate respiratory function. Two quantitative tests for airway obstruction in common use today, determination of the maximum breathing capacity[1] and determination of the timed vital capacity,[2] require special equipment not available at the bedside. In this report a simple, semiquantitative, bedside test for airway obstruction is evaluated.

The inability to blow out a match held near the open mouth depends on the velocity of air flow and thus may be affected by airway obstruction. We have standardized this procedure and in this report correlate the ability to blow out a match with the maximum breathing capacity and with the one-second timed vital capacity in 126 patients with various forms of pulmonary disease.

Method

Standard book matches are used. After the initial flare, when the match is burning steadily, it is held 6 in. from the patient's open mouth. The patient is first instructed to inspire maximally and then expire rapidly in an attempt to extinguish the burning match. *It is important that the patient not purse his* lips, for he must expire with his mouth completely open to measure true air-flow velocity. This procedure is repeated several times to assure maximal effort on the part of the patient. All patients tested in this study performed the timed (one-second) vital capacity (with use of the Gaensler-Collins Vitalometer) and maximum breathing capacity[3] tests, and results of these tests were correlated with those of the match test.

Results

A total of 126 patients were tested. Seventy-four were able to extinguish the match, using the method described, while 52 could not. The mean value of the one-second vital capacity for those who could not blow out the match was 0.97 liter with a standard deviation of ± 0.47 liter. For those who could extinguish the match the mean value for the one-second vital capacity was 2.49 liters with a standard deviation of ± 0.57 liter. Eighty-five per cent of the 52 patients who could not blow out the match had a one-second vital capacity below 1.60 liters, while 85% of the 74 patients who could blow out the match had a one-second vital capacity greater than 1.60 liters.

The 52 who could not blow out the match had an average maximum breathing capacity of 40.7 liters per minute with a standard deviation of ± 16.53 liters per minute. The 74 who could blow out the match had an average maximum breathing capacity of 93.0 liters per minute with a standard deviation of ± 25.85 liters per minute. Eighty per cent of the 52 who could not blow out the match had a maximum breathing capacity below 60 liters per minute, while 80% of the 74 who could extinguish the match had a maximum breathing capacity above 60 liters per minute (fig. 1 and 2).

The match test appears to be a fairly reliable semiquantitative guide to airway obstruction. It may fail to differentiate, however, certain patients with a greatly reduced total vital capacity due to pulmonary fibrosis and other conditions limiting expansion of the lungs from patients with airway obstruction. This is because the one-second vital capacity may be a normal percentage of the reduced total vital capacity but still inadequate to extinguish the match. The normal patient with a total vital capacity of 4,000 cc. usually exhales at least 3,200 cc. of this in the first second and, since this exceeds 1,600 cc., is able to extinguish the match. The patient with obstructive emphysema with a total vital capacity of 3,000 cc. cannot blow out the match, for it takes him over one second to exhale 1,600 cc. Results in two patients with restrictive pulmonary disease due to pulmonary fibrosis

---

From the Medical Service, Veterans Administration Hospital, Dearborn, Mich., and Wayne State University College of Medicine, Detroit.

are shown in figure 3 along with those of a normal subject and of a patient with pulmonary emphysema. Both patients with pulmonary fibrosis have low total vital capacities. However, one can exhale 1,600 cc. in the first second and can therefore blow out the match, while the other with a total vital capacity less than the required 1,600 cc. cannot blow out the match, even though neither has airway obstruction. Obviously, if the patient cannot extinguish the match more specific tests of pulmonary function should be performed.

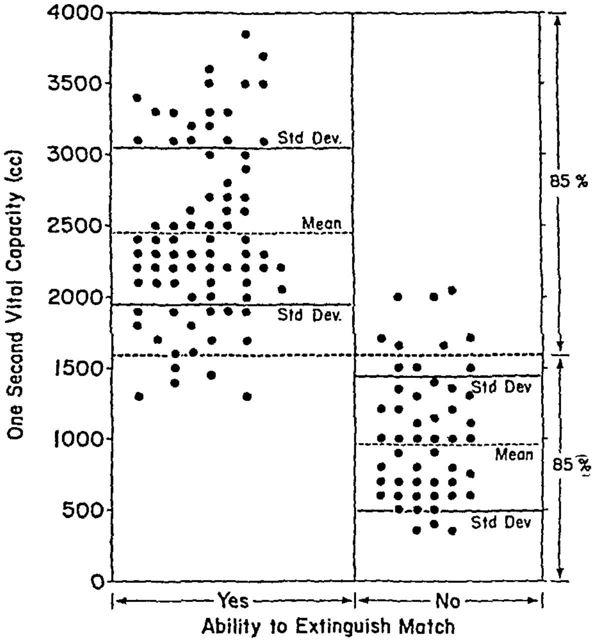

Fig. 1.—Results of one-second vital capacity match test.

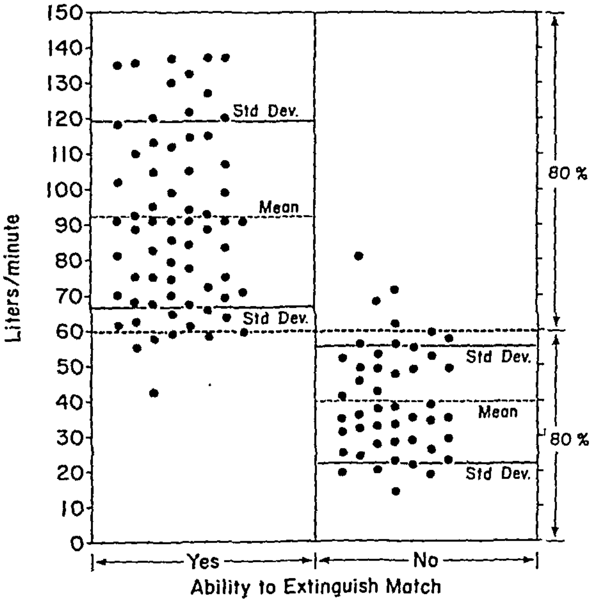

Fig. 2.—Maximum breathing capacity test results.

Summary

A simple semiquantitative test for airway obstruction is based on the patient's ability, by maximal expiration, to extinguish a match held 6 in. from the open mouth. Results of this test can be correlated with those of the one-second vital capacity and the maximum breathing capacity tests. Eighty per cent of the patients with a maximum breathing capacity above 60 liters per minute could extinguish the match, while 80% of those with a maximum breathing capacity below 60 liters per minute could not. Eighty-five per cent of those with a one-second vital capacity above 1.6 liters could extinguish the match, while 85% with a one-second vital capacity below 1.6 liters could not.

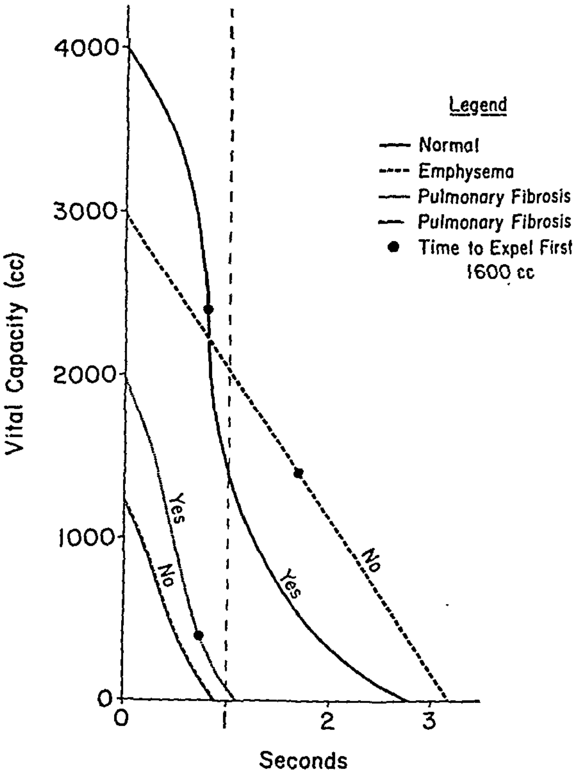

Fig. 3. Timed vital capacity in pulmonary disease.

Occasionally, patients with restrictive pulmonary disease will give results similar to those found in airway obstruction. Therefore, this test should be used only as a screening procedure; if results are abnormal, more specific tests of pulmonary function should be performed for exact diagnosis.

CLINICAL EVALUATION OF SALINE SOLUTION THERAPY IN BURN SHOCK

II. COMPARISON OF PLASMA THERAPY WITH SALINE SOLUTION THERAPY

Kehl Markley, M.D., Manuel Bocanegra, M.D., Augusto Bazan, M.D., Roberto Temple, M.D.
Miguel Chiappori, M.D., Guillermo Morales, M.D.
and
Alberto Carrion, M.D., Lima, Peru

In 79 burned adults, including 11 with burns of over 50%, treated with saline solution alone, there was no two-day mortality. In 74 other adults, including 14 with burns of over 50%, treated with plasma plus dextrose and water, there was a 12% two-day mortality. Selection of patients was made on a strictly alternating basis. In 73 burned children treated with saline solution alone, there was a 19% two-day mortality. In 92 other children treated with a combination of plasma and saline solution, there was only a 9% mortality. Saline solution therapy is considered good emergency therapy for adults, and addition of plasma to saline solution reduced the over-all acute mortality in children, particularly in the more severely burned.

This report of mortality and clinical data collected during the burn shock study in progress in Lima, Peru, is the second one of a series in which the efficacy of saline solution therapy is being evaluated. The administration of large quantities of saline solutions in burn shock stems from the experimental work summarized in a review by Rosenthal and Millican.[1] In the present study, the saline solutions for both oral and intravenous administration were isotonic saline solutions with electrolyte concentrations of sodium, chloride, and bicarbonate similar to those found in plasma of normal, healthy persons. The details of preparation are given in the earlier report.[2]

In the first report of this series,[2] one group of burned patients receiving only saline solution therapy in quantities roughly equivalent to 15% of body weight during the first 48-hour period after thermal trauma was compared on a strictly alternate case basis with another group receiving colloid (mostly plasma) supplemented by dextrose and water. Mortality during the shock period (48 hours) was used as the main criterion in evaluation of the efficacy of these therapies, since at the termination of the shock period there was no further difference in treatment of the two groups compared simultaneously. (The term "two-day mortality" is now being used in preference to 48-hour mortality, since the early mortality has been calculated in this paper, as it was in the first, to include all deaths up to 60 hours after burning.)

In adults, there was no mortality during the shock period in 40 patients treated with saline solutions as compared to a 10% early mortality in 43 patients treated with colloid supplemented by dextrose and water. The quantity of colloid administered was less than that recommended by Evans and co-workers[3] but represented the usual amount given to burned patients in Peru. Both groups showed a total mortality of 35%. Since the number of patients studied in each therapy group within each body-burn substratum was not sufficiently large at that time, it was not possible to conclude that the difference in two-day mortality was significant.

In a similar comparison of 110 burned children, there was no significant difference in two-day mortality between one group who received only saline solutions and the other group who received an adequate quantity of colloid supplemented by dextrose and water. The two-day mortality was 20% in both groups, with a 56% total mortality in the saline-treated patients as compared with a 62% total mortality in the colloid-treated patients.

In children, then, the mortality data demonstrated that adequate colloid therapy (mostly plasma) without adequate electrolyte therapy was not superior to treatment with saline solution alone. Since, however, most surgeons feel that treatment of burned patients with plasma is preferable to that with electrolytes alone,[4] the decision was made to investigate whether plasma combined with saline solution could significantly lower the early mortality below that seen with saline solution alone. This comparison was carried out in children, because (1) the results of the first therapy comparison in children were conclusive, while those in adults were not for lack of a large number of patients, and (2) since there was no (or very small) mortality from

---

shock in the adult patients treated with saline solution it would not be possible to demonstrate an added benefit from plasma during the shock period.

For purposes of clarity this report is divided into two sections: series A, a continuation of the adult study as before with data presented now over a seven-year period and after an accumulation of 153 cases and, series B, a four-year study in 165 children comparing two groups receiving the same total amount of saline solution but with one group receiving as part of the therapy an adequate amount of plasma.

Series A—Methods and Materials

This report presents the results on the study of 153 severely burned adults (83 of whom were included in the first report) between the ages of 12 and 73 years. Ninety per cent of the burns were due to flames or fire, while the rest were due to hot fluids. The following types of cases were excluded from the study: (1) burns involving less than 10% of body surface area, (2) pulmonary burns, (3) burns in patients over the age of 73, (4) burns not treated within eight hours after burning, and (5) cases in which death occurred within two hours after treatment had begun. The patients were brought to the hospital from one-half to four hours after thermal injury had occurred, at which time they were placed, with strict alternation, into one of the two therapy groups, "saline" or "colloid."

The patients in the saline group received an average quantity of isotonic saline solution (given by oral or intravenous route exclusively or by a combination of the two) equivalent to 10% of body weight during the first day after thermal trauma and half that amount the second day. No additional liquid was administered either orally or intravenously. At no time was blood, plasma, or colloid given to these patients during this 48-hour period.

The patients in the colloid group with more than 25% of their surface area burned received in divided doses an average quantity of 0.43 ml. of plasma, blood, or povidone per kilogram of body weight for each percentage of area burned up to a 50% burn (averaging 1.7% of body weight) during the first 24 hours after injury and approximately half that amount (averaging 1.1% of body weight) during the second 24-hour period. All additional liquid in this group was given as water orally or as 5% dextrose in water intravenously. Of the 33 patients with 10 to 25% of their surface area burned, 21 received an average quantity of colloid equivalent to that received by those with more extensive burns, while 12 received only dextrose and water but no colloid therapy, due to an inadequate supply of colloid during the early part of the project. The patients who received only dextrose and water have been included in the colloid group for completeness of presentation, since their exclusion would not alter the final results, due to the fact that no two-day mortality occurred in adults with this degree of burn either in this or in the saline group (table 1).

Of the 62 patients receiving colloid, 52 (84%) received plasma or dehydrated normal human blood plasma (Lyovac) during the first 48 hours after burning in quantities of 0.2 to 1.2 ml. (average, 0.61 ml.; standard deviation, ± 0.19 ml.) per kilogram of body weight for each percentage of area burned; 6 (10%) received blood during the first 48 hours after thermal injury in quantities varying from 0.08 to 0.6 ml. per kilogram of body weight for each percentage of area burned; and 4 (6%) received povidone during this period in quantities varying from 0.6 to 1.3 ml. per kilogram of body weight for each percentage of area burned. The total amount of liquid (dextrose, water, and colloid) given during the first 48 hours after burning averaged 10% of body weight.

It must be emphasized that treatment of the two simultaneously compared groups differed only during the first 48 hours after injury. When patients had survived that period, there was no difference in therapy between the groups, since plasma and blood were given when necessary thereafter.

Blood pressure, pulse rate, respiration rate, and rectal temperature were recorded on admission, and, if the patient manifested signs of shock with a systolic blood pressure lower than 90 mm. Hg, intravenous therapy was started and followed by oral administration of fluid when the patient's blood pressure rose above 90 mm. Hg. In both therapy groups, half of the liquid administered during the first 24 hours after burning was given 8 to 12 hours after burning. The oral administration of the saline solution was accomplished simply by drinking of the liquid. If repeated vomiting or diarrhea occurred, oral administration of fluid was suspended and the intravenous route was utilized. The speed and quantity of fluid ingested were carefully controlled and recorded, and vomitus and urine were collected and accurately measured during this period when possible. Blood pressure, pulse rate, respiration rate, and temperature were measured every two hours during the first two days. Clinical notes were made every six hours.

All accessory antibiotic and supportive therapy was identical in both groups compared simultaneously.[2] Local therapy consisted of the open method for a period of nine days, after which the burned areas were covered with Vaseline-coated gauze and a heavier layer of dry gauze. Grafting was practiced initially within the first 18-28 days after burning in the majority of patients.

Series A—Results

As a consequence of strictly alternating cases between the two therapy groups, material was obtained in comparable groups with respect to the following pertinent variables: (1) percentage of body surface area burned, (2) percentage of body surface area with full-thickness burn, (3) causative agent, (4) age, (5) sex, and (6) interval between thermal injury and commencement of therapy. The resulting data, therefore, can be analyzed by overall groups or by subgroups wherever the total numbers are large enough to permit valid comparisons.

Table 1 gives the number of patients in each stratum of percentage body burn, two-day mortality, late mortality, and total mortality in each group, and 95% confidence limits on the percentage of two-day, late, and total mortality. In adults, there was no two-day mortality over a seven-year period in 79 patients (including 11 patients with burns over 50% of body surface area) treated with saline solution and a 12% two-day mortality in 74 patients (including 14 patients with burns over 50%) treated with colloid supplemented by dextrose and water. Of the nine patients in this group who died from shock, eight received plasma or dehydrated normal human blood plasma and one received blood as the administered colloid therapy. This difference in early mortality is statistically significant and demonstrates the superiority of treatment during the shock period with large volumes of saline solution over treatment with "inadequate" colloid supplemented with dextrose and water. In the late and total mortality, however, there is no significant difference between the two groups. It is noteworthy that patients in each substratum with burns over 25% of the body surface area showed a total mortality of over 50%.

* 95% confidence limits connote that in repeated sampling 95% of the mortality percentages will fall between these limits. Any value that falls outside these limits is designated as significantly different. This statement will be expected to be incorrect with a probability of 1 in 20.

Percentage cumulative mortality in adults is plotted against time in figure 1*A*. The saline curve approaches the colloid curve only a fortnight after burning, and there is nothing to suggest that the administration of saline solutions caused an increase of mortality after the initial shock treatment period.

The routes by which the saline was given are listed in table 2. In burns of less than 50% of the body surface area in adults the majority of patients received the saline solution solely by the oral route, while more of the administered saline was given intravenously in the more serious burns, even though a fairly high percentage of these patients received some saline solution orally.

* Data for entire seven-year period.

Table 3 shows the incidence of toxic symptoms, including vomiting, diarrhea, and pulmonary edema, in adults and children treated over the seven-year period. In the adult patients who received only colloid supplemented with dextrose and water, the incidence of vomiting was significantly greater than in those who received saline solutions, while the incidence of diarrhea was slightly greater in the saline groups. It must be emphasized that no generalized and/or pulmonary edema was observed from clinical evidence or autopsy findings.

Table 3.—*Toxic Effects of Therapy During Shock Period*

Treatment Group	No. of Cases	Vomiting, %*	Diarrhea, %	Pulmonary Edema, %

Colloid	74	45	3	0
Series B, children				
Saline	73	14	12	0
Saline plus plasma	92	4	4	0

* Includes any vomiting after commencement of therapy.

As in the previous studies, an attempt has been made to evaluate therapy on the basis of its effect on clinical shock. Again blood pressure was selected as being, perhaps, the least subjective sign of shock. The incidence of hypotension in both therapy groups is illustrated in figure 2*B*. In general, the more extensive the burn, the greater was the incidence of hypotension at any time selected during the first 48-hour postburn period. In addition, the incidence of hypotension always increased for a minimum time of four hours after admission to the hospital, regardless of the therapy administered. In adults, both therapy groups showed a lower incidence of hypotension after fluid therapy had been administered than during the early course of the burn period, but the group that received inadequate colloid with dextrose and water demonstrated a higher incidence of hypotension at any time selected compared to the saline group.

Figure 3 illustrates the daily average urinary output with burns of increasing severity. In burns of 10 to 50% of the body surface area, where the number of patients studied was sufficiently large for statistical comparison, the 48-hour urinary output significantly ($p < 0.05$) decreased as the extension of the burn increased. The daily volume of urine was usually greater during the second 24-hour period after burning in both therapy groups. When the urinary volume was plotted as the percentage of ingested fluid excreted via the kidneys, the colloid group demonstrated a higher percentage of fluid excreted by the kidneys. Only the patients with 10 to 25% burns, however, showed a total 48-hour urine volume significantly different ($p < 0.05$) due to therapy.

Figure 4 demonstrates average weight changes over the initial weight and the percentage of fluid retained of the total amount of both adult groups. In burns up to 50% of the body surface area the patients in the saline group retained approximately 45% of the fluid administered during the first 24 hours after burning. This amount of fluid retained was 14% higher than that retained by a group of normal Peruvian persons given the same quantity of saline solution orally during the same time period.[5] Patients with extensive burns retained less fluid than those with moderate burns. Regardless of the severity of the burn, patients in the colloid group retained much less fluid than those in the saline group.

Series B—Methods and Materials

This study included 165 severely burned children between the ages of 2 months and 12 years. Sixty-one per cent of the burns were due to hot fluids, while the rest were due to flames or fire. Similar criteria for the exclusion of patients from the study were adopted as for adults. If the burn involved 10% or more of the body surface area, the patient was placed in one of the two therapy groups, "saline" or "saline plus plasma," with patients strictly alternated between these groups. The composition of the saline solutions administered was the same as of those given to adults.

The children in both the saline and saline plus plasma groups received a total amount of saline solution or saline solution plus plasma equivalent to 10% of body weight during the first 24 hours after burning and 5% of body weight during the second 24-hour period. Children in the saline plus plasma group, however, received as part of the total amount of fluid administered a quantity of plasma equal to 1 ml. of plasma or dehydrated normal human blood plasma per kilogram of body weight for each per-

Columns (*left to right*) represent admission, first 48-hour period after burning for minimum period of four hours, and end of 48 hours. Numbers above bars represent number of cases studied in each group.

centage of area burned, up to a maximum of 50% of the surface area burned (averaging 2.1% of body weight), during the first 24 hours after burning and half that amount in the second 24-hour period. The plasma was administered in divided doses, and the total quantity given was calculated from the formula of Evans and associates.[3] At no time during the first 48-hour period after thermal injury was any other type of fluid administered.

After 48 hours, there was no difference in therapy between the two groups. The clinical management was similar to that of adults. Infants were given fluid orally by constant drip technique with a tube passed through the nose to the stomach, whereas children over 2 years of age drank the saline solution. The criteria for giving the saline solution intravenously were the same as for adults.

Antibiotic therapy consisted of tetracycline in doses of 10 mg. per kilogram of body weight combined with polymyxin in doses of 2.5 mg. per kilogram of body weight. Because of the serious problem of Pseudomonas infection and septicemia as a major cause of late mortality,[6] a clinical evaluation of human gamma globulin was started during the last year and a half on the basis of the good results obtained with gamma globulin in the treatment of experimentally induced infections in mice.[7] Gamma globulin was administered intramuscularly on an alternate case basis in doses of 1 ml. per kilogram of body weight on the first, third, and sixth postburn days. The details of the gamma globulin study, which is under the direction of Dr. N. A. Kefalides, will be published later.

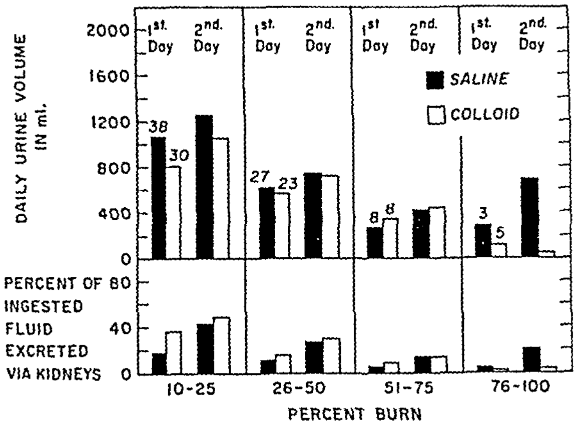

Fig. 3.—Average daily urinary output in burned adults (only patients in whom accurate urine collections could be accomplished are included). Numbers above bars represent number of cases studied in each group.

Accessory supportive therapy was the same as that previously described,[2] except that none of these children received desoxycorticosterone acetate. Local therapy consisted of washing the burned area with soap and saline solution, applying Prontyl (5.0 Gm. of azosulfanilamide, 0.05 Gm. of tetracaine, 12.5 Gm. of a solution of colloidal gelatin, and 100 ml. of distilled water) or an antiseptic to the wound, and covering the burn with Vaseline-coated gauze and dry gauze. Grafting was practiced initially within the first 18-28 days after burning in the majority of all patients.

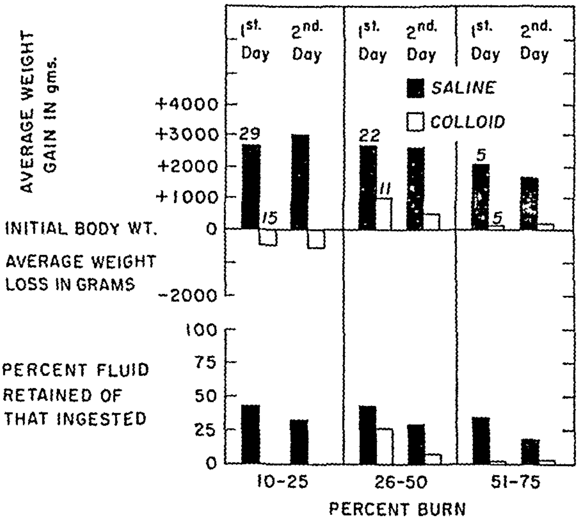

Fig. 4.—Average body weight change in burned adults. Numbers above bars represent number of cases used in computation of mean.

Series B—Results

The two-day mortality, late mortality, and total mortality are given in table 4 along with the 95% confidence limits. Again, as a consequence of strictly alternating the cases for treatment, material was obtained in comparable groups with respect to the same pertinent variables listed in the adult study. In children, there was a 19% two-day mortality in 73 patients treated with saline solutions and a 9% two-day mortality in 92 patients treated with ade-

quate plasma and saline. (The reason for the unequal numbers in these two groups is due to the fact that at the commencement of the project a strict alternation was used of two saline plus plasma cases for every one saline case, but after a year this plan was changed to alternation of single cases.) The over-all difference in early mortality is statistically significant and demonstrates that plasma combined with saline solution, as compared with saline solution alone, does improve survival, at least in children in Peru.

In the subgroup of 10 to 20% burns, the late mortality was significantly lowered by saline plus plasma therapy ($p < 0.05$), while the over-all late mortality showed no difference of statistical significance. The beneficial effect of plasma combined with saline solution was not only evident, therefore, in increasing survival during shock but also in decreasing late mortality in the 10-20% burns. The total mortality, nevertheless, remains high (over 59%) in burns of over 20% of body surface area regardless of initial therapy during the shock period.

Table 5.—*Influence of Age on Early and Late Mortality in Burned Children*

	Saline Solution Therapy						Saline Plus Plasma Therapy					
	10-30% Burn			31-100% Burn			10-30% Burn			31-100% Burn		
		Mortality, %			Mortality, %			Mortality, %			Mortality, %

Total	61	10	40	12	67	33	76	5	25	16	25	62

Percentage of cumulative mortality is shown in figure 1*B*. These curves demonstrate that in the third to seventh postburn days a 9% increase in mortality above the difference at the end of two days was reached by the saline group as compared to the saline plus plasma group, after which time there was no appreciable change in mortality difference between the two groups.

Table 5 shows that 47% of the total number of children treated were infants below 3 years of age. Both immediate and late mortality varied inversely with age in both therapy groups in burns of 10 to 30% of the body surface area, where the number of patients was sufficiently large to detect this trend. The table also shows that plasma added to saline therapy decreased acute and late mortality only in infants below 3 years of age in the 10-30% burn group. There was no significant increase in survival of children over 3 years of age treated with plasma. In the severe burns of more than 30% of the body surface area, however, plasma significantly decreased over-all immediate mortality.

The routes by which the saline solution was given to children are listed in table 2. In burns of less than 30% of the body surface area, the majority of patients receive the saline solution solely by the oral route, while with the more serious burns more of the administered saline solution was given intravenously, even though a fairly high percentage of these patients received some saline solution orally. Data have also been listed for the saline plus plasma group to demonstrate that there was no significant difference in the manner by which the saline solution was administered to account for the difference in mortality between the two therapy groups in children.

Table 3 shows that the incidence of vomiting and diarrhea was low in both groups with even fewer untoward effects observed in the group who received adequate plasma and saline. The data of the saline group presented here compared with that in the earlier publication[2] show a 50% decrease in the incidence of both vomiting and diarrhea during the past four years. This difference may be due to the experience gained in the more regularly spaced oral administration of saline solution and to the strict limitation of saline solution intake to 15% of body weight. Again there was no evidence of generalized or pulmonary edema.

The incidence of hypotension in both therapy comparisons is illustrated in figure 2*A*. In general, the more extensive the burn, the greater was the incidence of hypotension. The saline plus plasma group demonstrated a much lower incidence of hypotension at the termination of 48 hours than the group that received saline solution alone.

Comment

The two-day mortality data in adults demonstrate that a quantity of isotonic saline solution that is equivalent to 15% of the body weight is good therapy during the shock period, since there was no 60-hour mortality, even among 11 patients with burns of more than 50% of the body surface area. On the other hand, in the plasma plus dextrose group the over-all early mortality was 12%, while in 41 patients with greater than 25% surface area involvement it was 22%. The less favorable response in this group may be attributed to inadequate electrolyte therapy as well as inadequate plasma therapy. The fact remains, nevertheless, that therapy with adequate amounts of plasma could not improve on the zero mortality in the saline-treated patients, although it is possible that plasma given during the shock period might decrease late mortality. Whatever the arguments may be for the ideal therapy, we believe that all will agree that saline solution is good emergency therapy.

On the other hand, children treated with saline solutions demonstrated a 19-20% two-day mortality during two separate therapy comparisons. Why, then, was saline solution therapy more efficacious in adults than in children? The large number of infants below 3 years of age in whom early mortality was higher than that of the older children may have been responsible for this difference. The high early mortality may also have been related to the frequency of malnutrition in Peruvian infants.[8] The addition of plasma to saline solution therapy, at any rate, effectively reduced the overall acute mortality in children.

The influence of age on mortality was even more striking in late deaths. The high late mortality may have been related to the known susceptibility of infants to infection. Indeed, a large percentage of late deaths in infants was found to be associated with a Pseudomonas septicemia.[6] Plasma therapy may have reduced the late mortality in infants by the antibodies it supplied.

The question arises again as to whether these data from Peru are applicable in other parts of the world. Although no controlled comparison similar to the one in Peru has been made, Fox,[9] Moyer,[10] and Griswold [11] have reported success in the treatment of burned patients with the administration of large amounts of saline solutions during the early postburn period. Since there is no reason to believe that the mechanism of shock and the principles of replacement therapy are different in other parts of the world, even though differences in susceptibility may exist, there is every reason to expect similar results in other localities.

Summary and Conclusions

A study was made of 165 children and 153 adults from Peru suffering from burns that involved 10% or more of the body surface area. In burned children, treatment was strictly alternated between two groups receiving the same total amount of saline solution (15% of body weight) during the first 48-hour period after burning, but with one group receiving as part of its saline solution therapy an adequate amount of plasma (3.1% of body weight). In burned adults, treatment was strictly alternated between one group receiving a quantity of isotonic saline solution that was equivalent to 15% of body weight in the first 48-hour postburn period and another group receiving a quantity of colloid (mostly plasma), averaging 2.2% of body weight, supplemented by a quantity of dextrose and water equivalent to 7.8% of body weight.

The saline solution was administered almost exclusively by the oral route in burns of less than 50% in adults and less than 30% in children; nevertheless, even in the patients with more severe burns in both age groups a fairly high percentage of the saline solution administered was given orally. In general, saline solution was received by the patients without difficulty, and there was no serious evidence of toxic effects, such as persistent vomiting or diarrhea, generalized edema, or pulmonary edema.

There was no two-day mortality in 79 burned adults (including 11 with burns of over 50%) treated with saline solution alone, while there was a 12% two-day mortality in 74 burned adults (including 14 with burns of over 50%) treated with inadequate colloid supplemented with dextrose and water. This difference in two-day mortality was statistically significant. The late and total mortality, while fairly high, showed no difference of major significance.

In 73 burned children treated with saline solutions alone there was a 19% two-day mortality, while in 92 children treated with adequate plasma and saline solution there was only a 9% early mortality. This difference in early mortality showed statistical significance. The late mortality in the children with 10 to 20% burns was significantly lower in the saline plus plasma group, but the overall late mortality showed no difference of statistical significance between the two groups.

The two therapy comparisons reported here, in addition to a previous study comparing saline solution alone with adequate colloid and dextrose and water, furnish sufficient evidence to make the following conclusions: 1. In burned adults, isotonic saline solution given in quantities of 15% of body weight is effective therapy in preventing early deaths due to shock, since there was no mortality during the shock period in 79 burned adults. 2. In Peruvian children and infants, adequate plasma therapy combined with adequate amounts of saline solution is more effective than saline solution alone or adequate colloid and water alone in reducing early mortality. The effect of plasma in reducing early mortality was most prominent in the treatment of severe burns of more than 30% of the body surface area, whereas in the less severe burns the additive effect of plasma in decreasing early as well as late mortality was limited to infants below 3 years of age.

This study was supported by a grant from the National Institutes of Health and sponsored by the National Institute of Arthritis and Metabolic Diseases in cooperation with the Universidad Nacional Mayor de San Marcos, Lima, Peru.

Drs. I. S. Ravdin, Carl Moyer, and Jonathan Rhoads aided in formulating the procedures used. This work was carried out as a clinical extension of the findings of Drs.

Rosenthal, Tabor, and Millican in experimental animals and was conducted under the general supervision of Dr. Sanford M. Rosenthal.

Mr. Jacob Lieberman, National Institutes of Health, aided in statistical aspects of this study. Dr. Alberto Hurtado furnished laboratory space in the Departamento de Fisiopatología; Drs. Gilberto Morey and Carlos Martinez furnished facilities in the Hospital del Niño; and Drs. Belizario Sanchez and Fortunato Quesada furnished facilities in the Hospital Loayza and Hospital Dos de Mayo respectively.

The sterile solution for intravenous administration used in this study was supplied by Laboratories Unidos, Lima, Peru.

THE MECHANICS OF COMMON FOOTBALL INJURIES

Donald B. Slocum, M.D., Eugene, Ore.

Classifying the injuries incurred by football players has given valuable clues for prevention, diagnosis, and treatment. The upper extremity is less liable to injury than the lower because usually it bears little weight and is not fixed, but certain typical injuries to it do occur and are here analyzed. The lower extremity is usually fixed by contact with the ground and burdened by the weight of the rest of the body; injuries to the pelvis and lower extremity are therefore more frequent and severe. The head and vertebral column have rightly received more attention than other body segments because of the frequency of damage to the face and the seriousness of damage to the brain and spinal cord. Here probably the most lethal weapon in football is the oncoming knee, which exerts forces that must either be absorbed by the head or transmitted to the vertebral column. It may be necessary to redesign some of the protective equipment now in use, including the present-day facial protection bars.

It is the basic premise of this paper that football presents certain inescapable injury hazards, due to the very nature of this vigorous body-contact sport, and that a knowledge of the mechanics of these injuries is essential to adequate medical history and definitive diagnosis. It is not the purpose to discuss preventive measures, such as preparticipation physical examination, proper training and conditioning, thorough knowledge of game techniques, and proper use of protective equipment. Nor is the objective to discuss the proper classification of participants into different categories according to age, weight, coordination, and physiological and mental maturity. The manner in which injury may be incurred and the injuries most likely to occur in a given situation will be discussed. This subject has received only scant attention by the medical profession at large, but a small corps of active observers—the team physicians, the coaches, and the trainers—has long recognized the constantly recurring pattern of situations from which injuries are likely to arise. To minimize these situations they have developed rules and regulations, encouraged research and development of protective equipment (fig. 1), and altered coaching methods for the protection of the player.

From the Orthopaedic and Fracture Clinic.

Read before the Western Orthopedic Association, Portland, Ore., Oct. 22, 1958.

Be this as it may, injuries will occur and the value of an appreciation of injury mechanics under normal playing and practice conditions cannot be overestimated. It is fundamental that the early detection and prompt diagnosis and evaluation of injury is essential to the successful treatment of athletic trauma. Diagnosis can usually be made most accurately in the first few minutes after injury, prior to the onset of swelling and protective muscle spasm. Unfortunately, the physician seldom sees the player until hours or days after he has been injured. The well-trained player moves automatically, depending on training, instinct, and conditioning, and his attention is directed toward the constantly unfolding pattern of play rather than his position, posture, balance, speed, and mode of body contact. It is more than likely that he cannot give an accurate history until his memory is refreshed by the probing questions of a physician familiar with the type of injuries likely to occur and the mechanics of those injuries.

In this discussion, I will outline the mechanics of some of the more common injuries which are unique to the game and attempt to translate the "locker-room" slang for these injuries into medical terminology.

The Upper Extremity

The shoulder complex actually consists of four joints which, through coordinated interplay, place the arm in the many positions required in daily use. Of these, the sternoclavicular and scapulothoracic joints are rarely injured in football, and it is with the acromioclavicular and shoulder joints that the physician is primarily concerned. By nature these joints have little inherent mechanical stability but depend on ligamentous strength and muscle balance for their integrity. The glenoid fossa forms a shallow socket for the reception of the humeral head and articulates with only a small portion of its cartilaginous surface at any time. The articulation between the acromion and clavicle is of fingernail size, yet it represents the articular-osseous connection between arm and trunk. Variations in the shape of the joint lead to further instability: the joint may be smaller than normal in size, may be slanting rather than at right angles at the face of the joint, or may be set with the clavicle riding high at the acromial junction. The majority of injuries to these two joints result from contact with other players (63%), although contact of the shoulder with the ground forms an appreciable group (30%) and there are a few miscellaneous causes of injury.[1]

The types of injury, in order of frequency, are contusions of the shoulder, acromioclavicular joint injury, shoulder muscle strains, sprains and dislocations of the shoulder, fractures of the clavicle, and other miscellaneous traumatic conditions.[2] In athletic parlance,[3] the "shoulder pointer" means contusion of the acromion and adjacent deltoid at the "point" of the shoulder. "Shoulder separation" applies to sprains, subluxations, and dislocations of the acromioclavicular joint. "Shoulder strain" designates actual strain of the internal rotator cuff by direct pull, contusions of the rotator cuff by indirect force impinging it between the humeral head and acromion, and sprains and subluxation of the posterior aspect of the shoulder joint. "Dislocation" of the shoulder applies to anterior and inferior capsular involvement with subluxation or dislocation. "Shoulder nerve injury" is a syndrome characterized by pain and swelling of the deltoid, numbness of the hand of about five minutes' duration, followed by weakness in abduction lasting for about two weeks; it is due to contusion of the deltoid in combination with a mild traction injury to the brachial plexus or direct injury to the axillary nerve in the quadrilateral space. "Knocked-down shoulder" is the term applied to the protective position assumed after musculotendinous injury to the shoulder-neck interval and usually involves local muscle spasm of the trapezius, rhomboid, and cervical erector spinae muscles, accompanied by acute unilateral pain. The term "glass arm" does not apply to football since it is not primarily a throwing sport. Let us now look more specifically at the various mechanisms of injury.

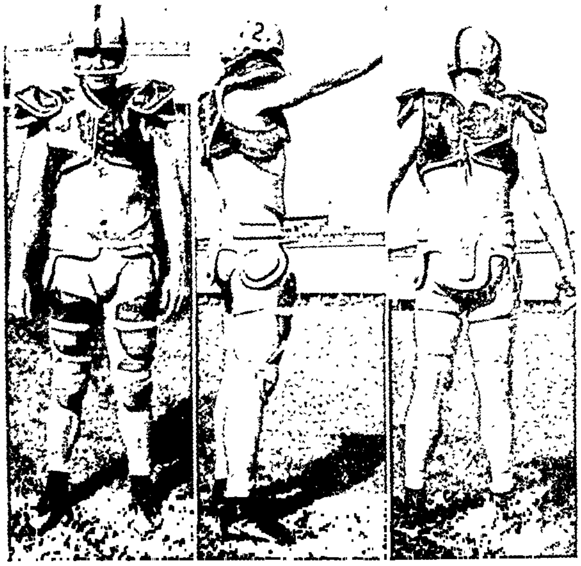

Fig. 1.—Football protective equipment. *Front view*, note headgear with bar protecting face. Within headgear is suspension, to distribute force of blow, with ⅝ in. clearance between scalp and shell. "Line-backer" shoulder pads distribute blow to shoulder area and thorax. *Side view*, note protection to roof of shoulder and deltoid region by shoulder pads. *Back view*, note protection to lower part of back and sacrum.

Mechanisms of Injury to Upper Extremity

The contusion of bone, muscle, or nerve is due to a direct blow. The roof of the shoulder and the shoulder-neck area are fairly well protected from such a blow by shoulder pads as long as these pads are properly sized and adjusted (fig. 1, *side view*). Only the trapezius and lateral part of the neck are exposed, and injury to this area most often occurs when the defensive player flinches and looks away from his opponent, taking a direct blow from the oncoming player's hip, thigh, knee, or elbow (fig. 2*A*). Trapezius injury may be incurred either from a direct contusion or sudden strong jerk on the arm while the head is being forced and rotated to the opposite side in a "pile-up" situation. Contusion of the brachial plexus usually results either from direct injury by the oncoming knee or thigh or from a downward blow on the shoulder resulting in impingement of the plexus between clavicle and ribs. Quadrilateral space injury is rare and is caused by a kick or blow from the knee. Contusion is usually of only transient importance since recovery time is seldom prolonged. Physical therapy methods are the chief form of treatment.

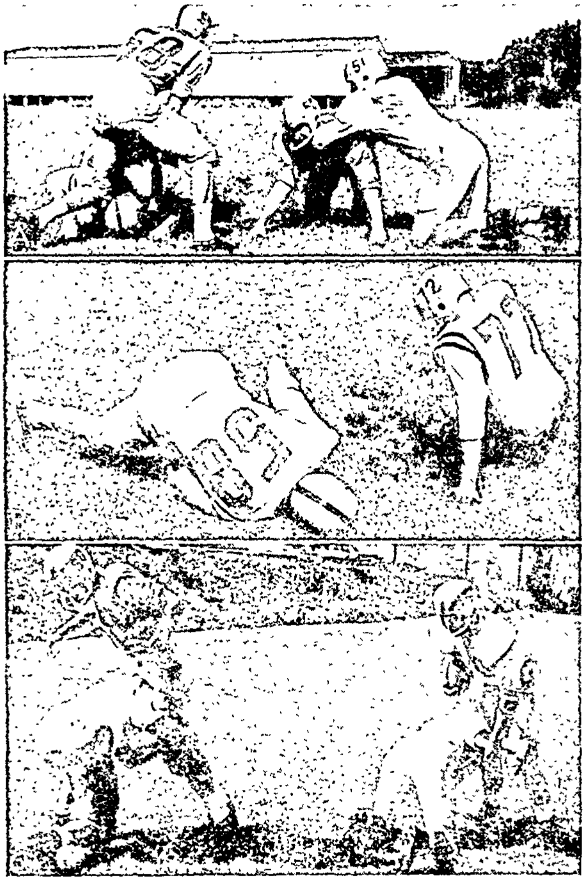

Fig. 2.—Injuries to shoulder-neck area. *A*, neck injury: defensive player exposes neck to block by dropping his head and failing to lift, probably due to flinching and closing eyes before moment of impact. He is likely to receive contusions of trapezius, cervical spine, and joint sprain. On right, player 50 looks away from defensive block, likely to cause head, neck, or facial injury. *B*, shoulder injury: player 58 is falling on "point" of shoulder, exposing himself to possibility of contusion of deltoid muscle and acromion, fracture of clavicle, and acromioclavicular sprain or dislocation. On right, player 72 has fallen with his arm at his side, exposing him to injuries of the wrist, elbow, and shoulder. *C*, two phases of mechanism of anterior dislocation of shoulder. On left, defending player tackles low and wide as ball carrier goes past. On right, his arm is being forced into abduction, extension, and external rotation.

Fractures of the clavicle are most often due to falls on the outstretched hand in which the force is transmitted upward through the shoulder and acromioclavicular joints to the clavicle. A lesser number are due to a fall on the point of the shoulder with inward force being carried through to the clavicle (fig. 2*B*). Fracture through direct injury is most rare because of the protective equipment, and for this reason fractures of the clavicle involving the underlying brachial plexus and subclavian vessels are seldom seen. It is obvious that most clavicular fractures are due to the failure of the player to absorb proper coaching techniques; in this case he fails to keep the body under control and to consummate a "body roll," in which the force of the blow is diffused by rolling backward over the posterior thorax and then into a prone position or onto the feet.[4]

The acromioclavicular articulation is subject to sprain, subluxation, or dislocation, all of which are due to essentially the same mechanics and are a matter of degree. Theoretically, this joint may be dislocated superiorly, anteriorly, posteriorly, or inferiorly. In football only the superior and anterior dislocations are seen. The superior dislocation is the usual one below the professional level of play and involves both the superior articular ligament of the acromioclavicular joint and the coracoclavicular ligaments. Its usual cause is a fall on the point of shoulder with forceful depression of the acromion. The arm is usually in moderate abduction, forward flexion, and internal rotation, i. e., the ball-carrying position. Such a dislocation is rarely the result of a blow directly on top of the shoulder because of the protection of the shoulder pads.

Cox[5] points out that in professional football a great number of anterior dislocations are seen, in contrast to college and high school football, in which practically none are to be found. There would seem to be two reasons for this: first, most professional players do not fall on the point of the shoulder because of previous training and developed agility; second, until recently, in professional football a player was permitted to get up and continue forward progress after his knee had touched the ground and, as he scrambled back to an erect position, an opponent or opponents would pile on his back, forcing his body forward and downward while the shoulder girdle was fixed by the extended arm or elbow.

Bateman[6] has pointed out that one result of superb mobility of the shoulder is frequent anterior dislocation and that the essential episode is the head of the humerus being forced against the weak anterior capsule. While the usual cause in civilian life is a fall on the outstretched hand in which the body weight carries forward and the elbow flexes, throwing the upper arm into abduction, external rotation, and extension, this only occasionally occurs in football because of training and the lack of a surprise situation. Here it is usually the result of a tackle in which the tackler looks away from his opponent and passes him too widely while attempting to grasp his thighs (fig. 2*C*); the momentum of the moving player and oncoming opponent then forces the abducted upper arm backward into full extension and levers it out of the joint. The inferior and the posterior dislocations have not occurred in my experience.

Sprain of the posterior capsule and posterior subluxation of the shoulder are frequent occurrences. They usually occur in unskilled players who have not learned falling techniques. The injury is most often sustained in ball carriers who fall on the point of the flexed elbow with the humerus in full forward flexion and moderate internal rotation. Force is transmitted upward through the humerus, and the humeral head is forced against the posterior capsule. Pain along the back of the shoulder joint and posterior instability of the shoulder may result. This injury does not often occur with falls on the outstretched hand, because there the elbow flexes and causes the shoulder to extend and the force is transmitted to the front rather than to the back portion of the shoulder capsule.

The internal rotator cuff may be damaged in several ways. In a fall with the arm near the side, force is transmitted directly upward, sandwiching the rotator cuff between the humeral head and the overlying acromion with resulting contusion. When the rapidly moving player is grasped by the arm and jerked, the downward or lateral traction against the fixed cuff muscles may strain or tear the muscular or tendinous fibers. In blocking, a strong blow on the abducted arm again may strain the fibers of the cuff.

Because of standard protective equipment, blows on the shoulder from above seldom traumatize the rotator cuff. Recognizable major tears in the cuff rarely occur in the football age group.

The upper arm is seldom affected by serious injury. Bruised muscles are frequent, and muscle strains are often encountered. Myositis ossificans occasionally develops in severely contused muscles. The radial nerve may be traumatized at the posterolateral aspect of the arm at the level of the middle third of the humerus.

Injuries to the elbow are usually easy to diagnose. Hyperextension sprain is common and results either from a fall on the outstretched arm or, more commonly, from a posterior blow on the fixed extended arm. Posterior dislocation has a similar mechanism. Other types of dislocation are unusual. Fractures of the medial epicondyle with tear of the medial ligaments are not infrequent; they follow a lateral blow on the extended elbow when the hand is fixed. In two cases seen this year, one player was grasping the jersey of an opponent and another had his hand on the ground and elbow extended while arising from the prone position. In contrast to nonsports injuries, lateral dislocation of the elbow is seldom found in conjunction with this injury. Radial head fractures result from the usual fall on the outstretched hand. The injuries associated with the throwing sports are scarcely ever encountered.

The forearm is seldom involved except through contusion. The hand is involved by the usual fractures, dislocations, and sprains with well-known mechanisms.

Pelvis and Lower Extremity

In general, the trauma sustained in the pelvis and lower extremity is more frequent and severe than that in the upper limb. In ligamentous injuries this results from the fact that the leg is fixed by the ground below and the body above when the force of a blow or indirect torsion strain is sustained. In contusions, the injury may be more severe than in the upper extremity because the part involved, the leg, is heavier than the arm, is probably moving with greater rapidity, and, of even greater significance, is superimposed by the entire body weight.

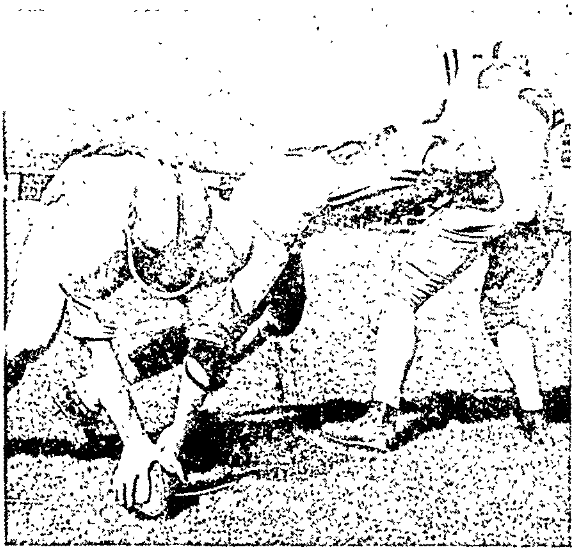

Fig. 3.—Mechanics of injury to iliac crest, flank, or lower chest wall. In this trap play, player 72 would have been faked out of position when ball was snapped and right guard would have pulled out behind center and would have struck defensive lineman from his blind side, forcing him out of play.

Contusions to the brim of the pelvis are called "hip pointers." These result from direct blows to the iliac crest and the musculature immediately above or below and are usually accompanied by hematoma formation (fig. 3). About 70% result from contact with other players (usually from "blind side" blows) or in pile-up situations.[1] In most instances they occur in spite of protective padding, but its absence or misuse will increase the likelihood of injury. The remaining 30% result from contact with other objects, such as the ground. With the exception of contusion of the greater trochanter of the femur, injuries to the hip region are few. The joint itself is seldom involved due to its protection by heavy muscles and the angle of application of traumatizing forces. Contusions of the thigh involving the quadriceps muscle are called "charleyhorses." These vary in severity from mild bruises to severe crushing injuries with rupture of muscle fibers and hematoma formation. When the latter occur in the vastus medialis, myositis ossificans may follow because of the intimate relation of this muscle with the underlying femur. In the majority of cases, the charleyhorse results from a strong shoulder block by the opponent, although the knee or foot may occasionally be the cause. It is more likely to occur if the thigh pads are loose or inadequate, but will often occur in spite of good protective equipment if the traumatizing force is great enough.

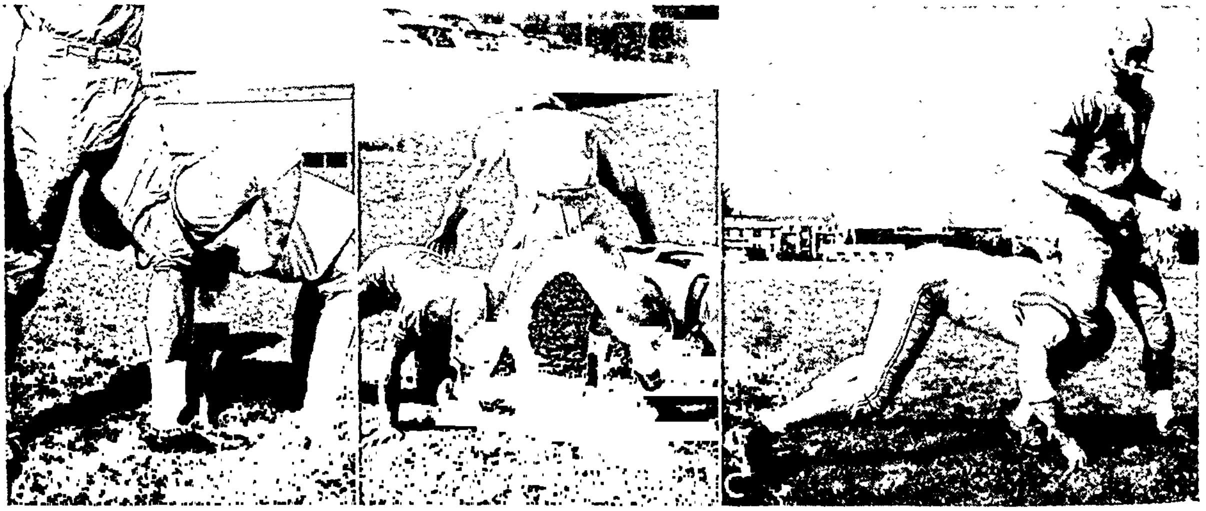

Fig. 4.—Knee injuries. *A*, contusion of knee by shoulder pad striking between thigh and knee pads. *B*, ligamentous injury to knee when defensive player 50 is subjected to "two on one" block by two offensive players. Normally, player would have his legs closer together and his feet in constant motion so that force could not be applied against his knees when his feet are solidly planted. *C*, player on left demonstrates typical clipping injury in which shoulder forces runner's knee inward and medial, while his cleats are fixed solidly to ground. Runner has complete loss of control and is subject to internal derangement of right knee. Injury varies, depending on whether force is applied from straight lateral or posterolateral position.

The knee presents a most vulnerable target for injury, due to its exposed position and to the fact that its movements are largely restricted to flexion and extension with little medial or lateral "give" (fig. 4). In contact injuries, 63% occur from the side, 28% from the front, and only 9% from the rear.[1]

Blows to the lateral side of the knee usually follow clipping, side-swiping, or trap blocking. To sustain ligamentous injury the foot must be fixed to the ground so that the force of the blow levers the inner side of the joint apart, with the outer bony rim acting as a fulcrum. If the foot is not fixed on the side of contact but the opposite foot is planted firmly on the ground, the force may be carried through to the opposite leg to lever the joint open laterally, rupturing the fibular collateral ligaments. The extent of cruciate ligament damage depends on the degree that the joint is opened on the side opposite the blow and the angle backward or forward of the lateral midline from which force is applied.

In frontal injury, contusions of the patella and suprapatellar region are incurred most frequently. The suprapatellar bursa which lies in the interval between the thigh and knee pads is most often injured by shoulder blows in tackling and blocking (fig. 4*A*). When a player takes blocks or tackles on his knees it is usually evidence of lack of ability, poor football preparation, or both. Bruises to the patella are often due to failure to use the protective knee pad; sometimes the pants are too tight, binding and restricting knee motion; often the pocket in which the pad should be inserted has shrunk from laundering until it is impossible to use the pad in it properly.

Contact at the back of the knee results in a straight forward or medial-and-forward force causing ruptures of the anterior cruciate and tibial collateral ligaments. In this instance, avulsion of the tibial collateral ligament at its distal attachment results in a tear which is greatest anteriorly; when it occurs at the femoral attachment it is greatest posteriorly; in the continuity of the ligament the tear may be at different levels in the superficial and deep layers of the ligament, and incomplete tears are located in the anterior or posterior side of the ligament in relation to their proximity to the upper or lower ligamentous attachment. In extremely severe contact injuries where torsion is present, the meniscus may be damaged. Muller,[7] reporting on 21 surgical cases of repair of severe ligamentous damage, states that in none of these was the meniscus injured. His findings suggest that twisting forces are not a major factor in most instances.

Noncontact injuries of the knee most frequently involve the meniscus and, to a lesser extent, the ligaments. They occur when the flexed knee is under a severe twisting strain, such as in the act of "cutting" where the player suddenly changes directions, often pivoting 90 degrees on the fixed foot. The question usually arises as to whether football cleats add to the likelihood of such an injury because of the fixation they afford. The weight of evidence points to the fact that aluminum, plastic, or composition cleats are readily withdrawn from the ground (in contrast to the old leather cleats) and are only dangerous when the foot is fixed, a situation which seldom occurs in the well-coached player. A second question which is often posed is whether ankle strapping, by restricting motion, causes more stress on the knee. Unquestionably it does but not to a degree which is dangerous to a properly trained player. Ankle injuries present no new problem as far as mechanism is concerned and will not be dealt with here except to point out the protective value of ankle wrap and ankle strapping; these reduce the incidence of sprain about 90%.

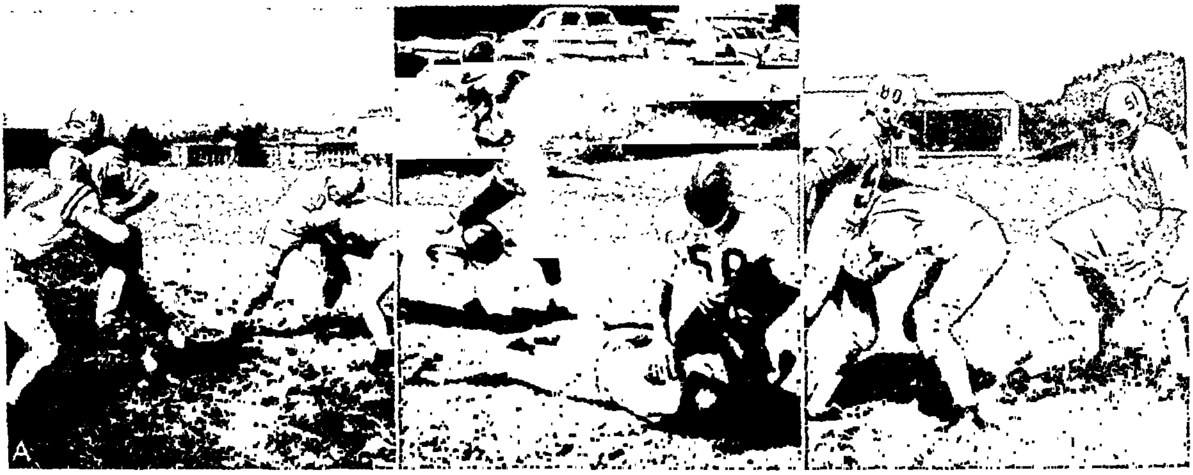

Fig. 5.—Injuries to head, neck, and spine. *A*, offensive player on left is out of football position while being tackled. Defensive player has used good technique, striking on-coming player immediately above belt line with his head, grasping his buttocks, and lifting upward to throw the ball carrier on his back. Helmet striking chin is likely to cause dental, facial, and neck injuries. Defensive player, driving in hard, will lift his head and shoulder, forcing his shoulder pads upward inside facial bar. This can result in facial injury or severe twisting of head and neck. *B*, player on left, tackling too low, is likely to sustain injury to trapezius muscle, cervical spine, or brachial plexus. Players on the right demonstrate second move of same play. Defensive player has completely lost control; spine is thrown into twist with possible back injury, and shoulder is rotated backward with possible contusion by offensive player's knee. He could sustain head or neck injury from offensive player's left knee. Situation is particularly bad in "gang" tackle. *C*, players on left demonstrate flexion injuries of the head, neck and back. Player 72 shows poor football technique by dropping his head on impact. This will result in blow on head plus acute flexion of neck. If player 80 moves forward he will raise his right thigh, throwing his opponent's back into acute flexion and exposing him to spinal injury through staggering force developed by oncoming knee. Defensive player on right is coming into his opponent too low—center of gravity is overbalanced, he has no lift to stop his opponent, and his head is twisted into position of possible neck injury. Spine is arched, which makes him liable to back injury as well.

The Head and Spine

Because of the frequency of facial injury and the seriousness of damage to the brain, the problem of trauma to the head has received more attention than that to any other body segment. Blows to the head may either injure the head itself or be transmitted to the spine, depending on their force and the angle of application (fig. 5). Blows are of two types: (1) the low-energy impact blow and (2) the high-energy impact blow. In the former, the current football helmet affords adequate protection against single or repeated blows, but these forces may be transmitted to the cervical spine where chronic sprain or cervical arthritis and its sequelae may result. The high-energy impact blow is the one which is potentially most dangerous and is responsible for the majority of fatalities. A study of location of the blow in fatal injury revealed[8] that "the left and right front side of the head incur 22.08 percent of all injuries. Blows on the top of the head (resulting in spine injuries) incur 18.83 percent. Internal injuries rank third with 18.18 percent. Traumatic blows to the back of the head incur 12.34 percent of all injuries."

The percentage of fatalities is relatively low (2 per 100,000 participants or 17.44 per year over the 1931-1956 period). Although no accurate statistics are available as to how these injuries have occurred, it is my feeling that the most lethal weapon in football is the oncoming knee. To give a rough example, a typical varsity fullback weighing 185 lb. (83.9 kg.) and running the 100-yard dash in 10.5 seconds was asked to kick a dynamometer with his knee. Standing, he could kick 500 lb., with one step 625 lb., and with two steps 725 lb. Add to this the increment of forces developed by rapidly moving players based on the formula "momentum equals mass times velocity" and a more realistic picture is presented. An aggressive, alert player may receive a serious head injury, and the weak, fatigued, or "loafing" player may be doubled up in flexion and receive serious spinal trauma.

Injuries to the spine are of two types: direct contusion and flexion or twisting injuries. The direct contusions are seldom serious, except for kidney blows. The indirect flexion injuries usually happen when a player (blocker or tackler) looks away from his opponent and is literally "doubled up" by the impact of the thigh or knee of an oncoming player. These may range from sprain to fracture of the cervical, thoracic, or lumbar spine. When a player loses body control at the time when strong body contact is faced, twisting injuries may be the result.

The face presents the single body area most vulnerable to injury. Here fractured teeth are most common, with the causative agent being the opponent's foot (25%), the head (18%), the knee (16%), and the arm (12%).[1] At a recent postgraduate conference, four outstanding college trainers seriously doubted the efficacy of present-day facial protection bars in reducing the incidence of facial injury; in fact, they felt that they might be responsible for a number of cervical sprains of the twisting type when grasped by an opponent, which frequently happens in spite of the 15-yard penalty rule.

Summary

Injuries due to football are the inherent risk of a vigorous body-contact sport. Early diagnosis is difficult under field conditions because of the pressure of time and lack of facilities for examination. Late diagnosis is handicapped by swelling and muscle spasm. A comprehensive understanding of injury mechanisms will often reveal the essential clues in the medical history that lead to prompt diagnosis and treatment.

CONSEQUENCES OF LIGATING THE PULMONARY ARTERY.—In the absence of infection, the pulmonary artery does not become thrombosed beyond the ligature, but comes into communication with vastly enlarged bronchial arteries by means of precapillary peripheral anastomoses. . . . It is remarkable that the lung can survive ligature of both pulmonary arterial inflow and pulmonary venous drainage. Collaterals arrive from both sides, in a manner characteristic for each when it alone is stimulated to expand as described. It is astonishing that the ingrowth of newly formed vessels arriving transpleurally is orderly, in that arterial collaterals invariably establish connections with pulmonary arteries, and the venous collaterals invariably come to drain pulmonary veins. The forces that guide these vessels to their appropriate destinations are mysterious, but must be chemical, rather than purely mechanical. If they were simply mechanical, then the larger than capillary connections should be in the direction of the greatest pressure drop, *i. e.* from collateral systemic arteries to collateral systemic veins. Such "short circuits" have, however, never been observed in the vinylite casts. Instead, the course of the blood flow is apparently the most circuitous possible: from systemic collaterals directly, by precapillary anastomoses, to pulmonary arteries, to pulmonary capillaries, to pulmonary veins, and thence, by large anastomoses, to systemic collateral veins. More than one influence must, therefore, be considered in the attempt to reply to John Hunter's still perplexing question, asked 200 years ago, "What makes vessels grow?"—A. A. Liebow, M. R. Hales, and W. E. Bloomer, Relation of Bronchial to Pulmonary Vascular Tree, edited by W. Adams and I. Veith, *Pulmonary Circulation,* 1959.

TISSUE NECROSIS AND SLOUGH PRODUCED BY METARAMINOL BITARTRATE

Walter E. Dippy, M.D.
and
Edward R. Dorney, M.D., Atlanta, Ga.

Tissue necrosis and slough occurred in a patient with generalized arteriosclerosis after intravenous infusion of metaraminol during which extravasation occurred along the course of the vein. Previously, multiple intramuscular injections of metaraminol had been well tolerated, as had intravenous infusions. It is suggested that, when metaraminol is used, all precautions against tissue damage, such as polyethylene catheters and phentolamine, should be used after extravasation in the presence of vascular insufficiency.

It has been reported that subcutaneous or intramuscular infiltration of metaraminol (Aramine) bitartrate causes no local tissue injury.[1] The purpose of this communication is to present a case of tissue necrosis caused by subcutaneous injection of metaraminol.

Report of a Case

A 65-year-old man was admitted to the Emory University Hospital, Atlanta, Ga., because of the sudden appearance of hemiplegia on the right side. He was said to have previously had transient episodes of slurring of speech and weakness of the right arm. No further medical history was available.

Physical examination revealed a blood pressure of 110/80 mm. Hg in the right arm, pulse rate 100 per minute; and temperature 98.6 F (37.5 C). There was a complete right-sided hemiplegia, with sensory loss on the same side and inability to speak or swallow. There was a loud systolic bruit heard over the left carotid artery at the angle of the jaw. A systolic thrill was palpable in the same area. A bruit of less intensity was heard in the same area on the right side. The heart and lungs were within normal limits. The abdomen was flaccid. The aorta could be palpated to the level of the umbilicus, but no pulsations were present below this level. No arterial pulses were noted in femoral or popliteal arteries or arteries of the feet. Pulsations were noted in the right radial artery but not in the left. Oscillometry revealed less than 0.2 of one unit of oscillation in the thighs, calves, and feet bilaterally at 60 mm. Hg. The lower right arm showed 2.5 units, upper right arm 2.5 units, lower left arm less than 0.5 units, and upper left arm 1.5 units at 60 mm. Hg. A diagnosis of generalized arteriosclerosis with left carotid artery thrombosis was made, and the patient was placed on therapy with anticoagulants.

On the ninth hospital day, a drop in the blood pressure was noted and 2.5 mg. of metaraminol was given intravenously. The pressure was then maintained with 10 mg. of metaraminol and 1,000 cc. of a 5% solution of dextrose and water for the next seven hours. After this, intramuscular injections of 2.5 mg. of metaraminol at two-to-four-hour intervals were continued for the next several days. On the 14th hospital day, the blood pressure again dropped to 70/40 mm. Hg and could not be restored by use of metaraminol intramuscularly. An intravenous infusion was then instituted in the right antecubital vein. Over the next three hours the patient received 1,600 cc. of the infusion containing 30 mg. of metaraminol per 1,000 cc. The infusion was stopped when subcutaneous infiltration occurred. To facilitate nursing care, the infusion was restarted in the right great saphenous vein at the ankle. A total of 75 mg. of metaraminol in 2,600 cc. of 5% solution of dextrose and water was given over the next 24 hours. The infusion was terminated when mild swelling of the lower portion of the leg was noted. Approximately nine hours later a discoloration was noted to extend along the course of the right great saphenous vein to the knee. In 72 hours the area had become dark and necrotic and drainage was noted. Treatment consisted of soaks, streptokinase-streptodornase (Varidase) topically, antibiotics parenterally, and débridement. Amputation was decided on, but the patient died of bronchial pneumonia before this could be carried out.

Postmortem examination showed generalized arteriosclerosis with occlusion of the terminal aorta just below the origin of the renal arteries, occlusion of the left internal carotid artery, and partial occlusion of the right internal carotid artery.

From the Emory University School of Medicine.

Comment

Tissue necrosis and slough occurred in the leg of a patient with severe atherosclerosis who was subjected to a slow intravenous infusion of metaraminol over a period of 72 hours. Concentrations of the agent used were not excessive, but there was subcutaneous extravasation along the course of the vein. Multiple intramuscular injections in the adequately vascularized upper arms and shoulders were well tolerated, as were intravenous infusions and one episode of subcutaneous infiltration. It seems logical, however, that any potent vasoconstrictor drug, when used in the presence of arterial insufficiency, is a potential cause of tissue necrosis.

It is suggested that, when metaraminol is used, all precautions against tissue damage, such as polyethylene catheters and phentolamine (Regitine)[2] in the local area after extravasation, should be utilized, particularly in the presence of vascular insufficiency.

SOCIOCULTURAL STRESSES AND THE PHYSICIAN-PATIENT RELATIONSHIP

Rodger L. Buck, M.D., Cambridge, Mass.

The phrase "physician-patient relationship" is heard more today than ever before, and it seems destined to be the object of even greater interest in the immediate future. The concept is not new, but it has been undergoing considerable modification and clarification.

Throughout the greater part of the history of modern medicine the interaction between a physician and his patient has been known to be important. Few physicians today would challenge the observation that success and prestige in the community depend more on "the little things" that impress the patient than on mastery of the technical skills. "Old Doc Brown may not be up to date, but he understands me." "Dr. Jones has a way with people." How often have we all heard similar comments? And that old wheeze "bedside manner" still pops up from time to time. Have we not all at one time or another noted a seeming disparity between competence and popularity with patients? Perhaps we have even heard a somewhat embittered colleague mutter something to this effect, "I'm not trying to win a popularity contest, I just want to practice good medicine."

Having a "way with people" is certainly no substitute for sound medical principles. Nor, on the other hand, are these two in any way antagonistic. It is better to perceive them as complementary forces. One need not exert his imagination to recall valid reasons why a good physician-patient relationship is essential for optimal patient care. Only a few examples need be listed here.

"History is 60% of the diagnosis" has long been a medical axiom. But history-taking involves the always complicated process of communication, which, in turn, is heavily dependent on the relationship which exists between patient and physician. Communication, faith in the physician, and the content of the interpersonal relationship may well determine to what extent, or how accurately, the patient follows his physician's orders.

There is a growing awareness, especially among the behavioral scientists, that the total content of the physician-patient relationship might well influence the speed or extent of a patient's recovery from almost any form of illness. This hypothesis remains to be tested thoroughly, but research with burned patients, patients undergoing colostomies, and those with cardiac disease, to name a few examples, has brought significant findings to light. I anticipate that further research may well extend even to such areas as convalescence after appendectomy or cholecystectomy.

If one might accept as a given fact that a successful physician-patient relationship is, indeed, important in the over-all patient care, consideration can be given to the thesis of this paper: a number of social, cultural, and economic forces are acting to widen the gap between physician and patient. Furthermore, many of these factors which create

---

From the Department of Social Relations, Harvard University.

stress in the physician-patient relationship are, paradoxically, elements which demand a narrowing of this gap.

Some of the elements which exert pressures predominantly on the patient side of this relationship will be reviewed first. Then, after considering those involving both sides simultaneously, the elements affecting the physician primarily will be discussed. The shift from one area to another will be almost imperceptible. This is as it should be. The interest here is in the meeting ground between patient and physician, and any stress (regardless of its primary focus) will be felt throughout the whole.

Publicity Pressures

A high proportion of newspapers now carry daily columns discussing health and illness. One after another, diseases, their symptoms and treatment, are sketched. Many leading magazines find it profitable to feature sections on medicine. Campaigns for funds and for the dissemination of information on poliomyelitis, tuberculosis, multiple sclerosis, muscular dystrophy, heart disease, cancer, cerebral palsy, arthritis, and influenza bombard the laity from all sides via every medium of advertising. (Diabetes even influenced the Davis Cup matches.) All of these lead to an increased awareness on the part of the laity of the potential hazards that jeopardize their chances for a long and healthy life. Anxiety is created, not only about their health but about their illness or their real or supposed symptoms. Mental illness statistics and the whole problem of mental health are claiming greater degrees of public attention, serving to bring the awareness of the possibility of developing a mental disease ever closer to each individual. Add to this the anxiety engendered by the succession of international crises, tension, and the threat of total annihilation of mankind, and the sum is the realization that our very existence is threatened—internally as well as externally.

All of these forces—increased medical knowledge, stimulated awareness of diseases, the threat of mental illness, and the imminence of annihilation—create an increasing need for the services of the physician. They also serve to make the patient more demanding (whether overtly or covertly) of increased time and attention from his doctor. Patients want more explanations, need more reassurance, and require more understanding.

These forces acting on the patient, although tending on the surface to draw the physician and patient closer together, actually make the existing gulf more apparent. A patient without these increased expectations, given a certain unit of the physician's time, will be more satisfied than the anxious and demanding patient given the same time. Perception of the physician-patient contact thus suffers a temporal distortion.

Further stress is exerted on the physician-patient relationship by the publicity so often given to attacks on the medical profession. Malpractice suits with skyrocketing claims and settlements make headlines. Sensational literature "exposing" hospital practices and physicians' conduct seems to be in vogue. Who can doubt the damage this does to the physician-patient relationship? Suspicion of the physician and diminution of faith in his skills are certain to take their toll.

Of course, there is another edge to this sword of damaging publicity. The physician finds himself more and more on the defensive—at times even apologetic. He is, at the same time, kept constantly aware of the threat of a malpractice suit. He is never certain just which of his patients may decide to take advantage of him; he may feel impelled to adopt an overly conservative style in all his therapy; and he is, in general, working under added pressures of anxiety. These factors may easily influence his relationship with all his patients. An optimal physician-patient interchange is undoubtedly based on mutual trust and respect. When suspicion, fear, tension, and loss of faith enter into one or both sides of the relationship, the entire relationship quite obviously suffers. Damage is done. The extent will depend on the degree to which these destructive elements are present.

Stresses due to Change in Therapy Environment

During the past 50 years, and especially during the span of the last generation, there has been a noted shift from home and family centered treatment to that of the hospital environment. Most of us will recall that during our own childhood the vast majority of illnesses were treated at home. The patient's family were constantly present to lend emotional support, to show their concern, and to be available at the patient's beck and call. The physician who attended the patient in the home became well acquainted with the family, the patient's living conditions, and other environmental factors. In essence, the physician was exposed to the psychological, social, and cultural factors, as well as the biological.

Today, as is well known, we are in the age of technological medicine. A far broader spectrum of diseases are treated in the hospital, where are concentrated a most imposing array of new techniques and technical personnel. Routines and procedures approach automation.

The technical advantages of hospitalization to the patient could not, for the most part, be duplicated in the home. Unfortunately, however, the psychological and social advantages of the family milieu are not sufficiently reproduced in the impersonalized hospital routine. The paradox is defined more sharply by our growing awareness that the dichotomy between the biophysical and the sociopsychological aspects of medicine is not a valid one. Man is at the same time a biological, a psychological, a sociological, and a cultural organism.

The stresses placed on the patient as the result of the change to a hospital environment are becoming more apparent as further sophistication in a more holistic approach to medicine is gained. It is realized, further, that in this age of technological medicine the physician is frequently denied the insights he previously gained from observing the patient in his home and with his family. It is evident, therefore, that the physician-patient relationship suffers stress bilaterally.

Problem of Specialization

Some of the side-effects of the current trend toward specialization are a further problem arising from our technological status. The mushrooming accumulation of medical knowledge precludes the attainment by any one physician of sufficient knowledge of all the specialties. Specialization is an obvious necessity; the only question concerns the optimal extent to which it should be carried. However, the very fact that there are general practitioners plus multiple specialties and specialists sets in motion considerable forces opposing a good physician-patient relationship.

The already doubting patient may harbor further suspicions that his family physician may not be quite qualified to handle his present illness. Or, if under the care of a specialist, he may wonder if the proper one has been engaged. Again a lessening of faith in the physician weakens the relationship. On the other side of the coin, it is conceivable that quite the opposite reaction may occur. A patient may enter his contract with a specialist with unjustifiably high expectations.

Effects of Prepaid Insurance

It is hoped that research may soon be initiated to determine the effects of prepaid insurance and group health plans on the physician-patient relationship. It is conceivable that under these circumstances there might be a tendency for people to view the physician as a salaried employee who is obliged to render all due medical care. Aside from the possibility of abuse of the medical plan and of the physician's time, there may well be other factors here that will have bearing on the relationship. For example, does the physician lose prestige to the extent that his leverage is decreased? Or, on the other hand, is there a tendency for the physician to perceive his patients as detached case numbers to be inserted in form 2A4XY? It may well be that more advantages than disadvantages will accrue from prepaid plans, but until adequate studies are done we must be cognizant of both possibilities.

Educational Lag

Returning to the matter of the accelerating accumulation of medical knowledge and the evolution of the holistic approach, it is noted that there are resultant educational lags. Practicing physicians are unable to avail themselves sufficiently of the growing mass of literature on the behavioral sciences. Medical schools, for that matter, are only beginning to include behavioral science material in the medical curriculum. Not the least of their problems derive from the dilemma of how to include this in an already overcrowded four-year program.

Partial solutions to many of the physician-patient relationship perplexities are becoming available as a result of significant interdisciplinary research in the field of social science in medicine. Adequate dissemination and implementation of this information has yet to be achieved. And the very absence of these new methods in their armamentarium causes many physicians to feel uneasy and insecure when confronted by psychosomatic cases. Lack of training in the behavioral sciences, and the resulting incertitude, may well reflect on relationships with patients.

Economic Stress

Stresses of economic etiology are equally apparent. Increased costs of living, of equipment, office rent, office personnel, malpractice insurance, etc., seem to leave the physician with but two alternatives, if he is to maintain his standard of living. He may (1) charge higher fees for services or (2) handle more patients. The first may arouse antipathy in certain patients, on the one hand, or compound the anxiety and reluctance that many physicians suffer from the discussion of fees, on the other. The second alternative increases the physician's pressures and fatigue and, at the same time, shortens the period of contact with each patient (many of whom need more, rather than less, time).

Sociopolitical Factors

I will not attempt to discuss the reasons, but physicians today seldom assume the community leadership roles of their predecessors. A family physician who was at the same time a leader in the community commanded prestige from his patients. He was respected for his active concern in the patient and in the patient's community. There was less chance of his having to labor under the stigma of a label of commercialism imposed by a suspicious or poorly informed public.

Conclusions

It has been the purpose of this paper to create further awareness of the sociocultural factors which cause stress in the physician-patient relationship. In revealing the widening gap between a patient and his physician it was not my intention to be pessimistic. There is too much of this already. Instructors of executive development courses say, "The definition of the problem is the biggest step toward its correction." Once we are aware that trouble does, in fact, exist, we must determine as precisely as possible the factors involved and how they may be remedied.

Examination of the problem of the widening gap in the physician-patient relationship demonstrates that forces are involved that necessitate assistance from beyond the ranks of the medical profession. Solution of this problem will be a task for research and other collaboration between social science and medicine.

THE PSYCHOTHERAPEUTIC APPROACH TO NEUROSIS IN THE PAVLOVIAN SCHOOL

George Serban, M.D., Elmhurst, N. Y.

According to Pavlovian principles, the social factor is important in forming the personality. Hence, in a Marxist society there should be little conflict between society and the individual. Conflict can, however, result from disequilibrium between social forces and individual capacities. Deviations must be corrected by persuasion, suggestion, punishment, or in special cases by treatment. Three case histories illustrate the application of these principles in patients with anxiety reaction, depressive reaction, and hysterical conversion. Little attention is paid to infancy as a nucleus of later conflict, to sexual problems, which are solved by the relative sexual freedom of the adolescent, or to worries about the social security, which has to be accepted by the individual as it is offered by society. In this context, the psychiatrist and his patient, as products of the same society, have no choice, and psychotherapy simply aims to reconstruct the broken socially conditioned reflexes by verboverbal associations to a certain type of nervous system.

American writers whose studies refer to Pavlovian psychiatry and psychology appear surprised by the lack of information about Pavlovian psychotherapy in the Russian medical literature. Similarly, American textbooks of psychiatry or psychotherapy [1] do not mention any point of view about it. Salter presents a conditioned reflex therapy fragmentarily, but not quite in the Pavlovian conception. Laughlin [2] discusses Russian brainwashing without any special theoretical approach.

Inevitably then everybody has the impression that psychotherapy is not taken into consideration by the Pavlovians. Consequently, the question might arise as to the method of treatment and kind of psychotherapy they would use, if any. Generally the same drugs, shock treatment, and other physical therapies are used all over the world. Knowing that these cannot always heal the patients, this raises the question, "Are they treated in the best way?" Moreover, the fact that only the usual medication in the treatment of psychiatric disorders is referred to in the Soviet books [3] strengthens the impression that the patients are treated by no other means.

What is the explanation of the silence that covers Pavlovian psychotherapy? To understand the underlying facts of this situation is to understand the philosophical and practical approach to human relations in the Soviet type of society. It is necessary, therefore, to discuss briefly the formulation of the human concept in the dialectical materialistic view, which considers, according to Marx, "men as a product of circumstances and upbringing, and, consequently, changed men are products of other circumstances." [4] However, it would be a scientific error to interpret the above principle mechanically. The human being, in the materialistic philosophical concept, is not mere passive matter yielded to the power of environmental influences but an active purposive participant in it. Under these conditions the man creates his own milieu by his own work and activity, and any transformation in the content or form of everyday activity can produce changes in the psychic properties and in any stage of formation of mental processes.[5]

From City Hospital at Elmhurst.

Read before the periodic neuropsychiatric meeting, Beth Israel Hospital, New York, Dec. 4, 1958.

In this sequence of logical deduction, mental activity becomes the result of a report of interrelations between the human being and his environment. Generalizing the idea, human life became a new mode of existence of matter developed at a certain level. In supporting this point of view, it is best to quote directly from the materialistic philosophical interpretation of matter in motion according to Ananiev [6]; this will provide a clearer understanding of Pavlovian psychological orientation: There are different forms of movements of matter, from simple mechanical movements to the complex sensation. Sensation is an image of matter in motion as the most elementary element of consciousness directly reflecting the external world image. Space and time are regarded as the basic form of existence of matter in motion.[6A] This sustains the dialectical materialistic concept of quantitative changes being succeeded by qualitative changes as a transitory form of matter in motion to a new stage of existence. In other words, mental activity is conditioned by the form of existence of living beings and changes with the change in the existence, because "the matter is primary and the consciousness is secondary."[6A]

From this idea arises the well-known axiom of dialectical materialism that nothing can appear in consciousness which is not a reflection of some aspect of the objective world. But how?

We have to keep in mind that mental activity is the result of matter in its highest form of organization as a nervous system. The material basis for consciousness is the function of the brain. According to Pavlovians, consciousness is determined by existence but conditioned through the physiological activity of the nervous system. If mental activity is inseparably connected with the functioning of the brain, being a result of the latter, they might be studied by the same methods—materialistic methods. The successful representatives of this physiological school are Sechenov, Pavlov, and Ivanov-Smolensky. Russian psychiatry, oriented physiologically and sociologically, in its desire to find a solid ground in the explanation of the mental disorders had to consider the same approach.

Viewpoint of Russian Psychiatry

Although I have no intention of extensively discussing the point of view of Russian psychiatry, an outline of their general opinion is necessary for a better understanding of their psychotherapy. According to them, the general lines of mental activity of the brain are organized through unconditioned reflexes (which are inherited and, therefore, constant and phylogenetic) and through conditioned reflexes (which represent temporary bonds, highly variable in their connection, as the expression of the relations between environment and organism). The latter are acquired in the course of ontogenesis. Stated in broad terms, the conditioned reflex is formed due to an excitation which occurs simultaneously at two points in the central nervous system, making a connection or a coupling of them. Among the most important laws governing their formation, the laws of irradiation, concentration, and reciprocal induction play an important part in the explanation of the formation of the neuroses. According to these laws, mental disorders could be produced by disequilibrium between the processes of excitation and inhibition at the cortical and subcortical center, with the result of uncontrolled excitation foci which disorganize the normal brain functioning.

Pavlov [7] introduced the idea that the interplay of excitation and inhibition varies from individual to individual, depending on the type of nervous system. He categorized the mechanism of conditioned reflexes and their results according to the type of nervous system. As a sketchy review, there are four types: (1) strong unbalanced, (2) strong balanced, mobile, (3) strong balanced, immobile, and (4) weak. Every Russian psychiatry book discusses this at length.

The interrelation between the activity of the brain in the formation of cognitive processes and the type of nervous system might be summarized as follows: The sensation which represents the external stimuli is sent to the primary cortical sensory area, which has the function of analyzing, and it is synthesized by a secondary area into perception, into a conscious integrated nature, obtaining a stereotype of reaction.[8] The cognitive process, therefore, is always the reflection of the reality of the external world, but, as we know, there is a potential conflict between the amount and the quality of excitation and inhibition, as a physiological process in the mechanism of cerebral activity, in a certain type of nervous system. It remains necessary for the psychiatrist to recognize the quantity and the quality of stimuli that can be sustained by the individual with his particular type of nervous system in the formation of the dynamic stereotype. In support of the above idea, one has to recall the experimental work of Ivanov-Smolensky, who produced in the laboratory so-called neuroses of excitation and inhibition in healthy human beings.

In corroborating their view about the type of nervous system, Saprykin and Milerian [9] found that a conditioned reflex, established by pressing a colored button and the resulting appearance of a light of the same color, easily became strict; and by changing the speed of reaction they introduced the element of differentiation of conditioned stimuli in determining the type of nervous system. (The basic work was done by Ivanov-Smolensky.)

To summarize the general facts presented above, the psychotherapist has to keep in mind both the dialectical materialistic orientation of the society in which the individual is a purposive actor and the reaction of the individual, with his distinct personality, including his type of nervous system.

The physiological interrelation between the external world and the nervous system is presented by Bâkov,[10] referring to Pavlov, in this way: "Any element in the external environment which is indifferent for the organism may, under a certain condition, become a factor acting upon its central nervous system through the receptors. Under this condition, the action of neutral elements of the external environment may produce change in the organism." In line with this, Ilyina[11] made the same strong connection between the social reaction and the different types of nervous system (experiments correlating galvanic skin reflexes and the establishment of social contact).

Social Factor in Development of Personality

Briefly, all the Russian psychological papers, emphasizing dialectical materialistic thinking and physiological Pavlovian orientation, stress the importance of the social factor in the formation of personality. If this is so, first, in the Russian-Marxist society what may influence the development of the individual? Second, since the Russian psychiatrist is convinced that the personality is developed through social interaction, according to the type of nervous system, how will he analyze the social factor as a possible source of conflict for the individual?

The point of departure is the materialistic theme that the consciousness is a reflection of the objective world, is formed by the process of labor, and appears during human activity. This means that the society influences the individual by its people and by its principles.[12] But what are the principles of this society? Can these principles of society become a source of conflict between the society and the individual?

To understand all these remarks and the position of the psychotherapist, we have to take a brief look at the Russian-Marxist social organization. A society with an economic and social organization planned and directed by the central government implies in its structure, as a decisive factor, that the state has a dominant role over the individual. In this situation, the individual, regardless of his aims, is subordinated to the interest of the state. This society has strict regulations and dogmas in which the individual is supposed to believe, without hesitation, after a long process of learning and education organized by the state. The child's upbringing, education by the school, literature, radio and television, and social life are directed to form these temporary nervous bonds (conditioned reflexes) in supporting the aims of the state and stimulating the individual to them. Even the instinctual drive is channeled according to the necessity of the state.

Any deviation, sometimes unintentional, has to be corrected by persuasion, suggestion, or any form of social punishment. The individual, as in any society under social pressure, may present signs of neurotic reaction and, fighting more or less consciously and deliberately against the unlimited state authority, escape into sickness. The psychiatrist, using scientific methods, has to establish a balance of forces between the individual and the state, thus recuperating the individual for society. But the psychiatrist himself, as a member of this society, cannot admit that the conflict is caused completely by the social organization. According to philosophical materialism this society has solved the conflict of interests of the individual and society. Only the social productive relation and economic factors in the capitalistic order can be a source of personality conflict (Marx). The psychiatrist does not overlook the social factor, but, since it is a generalized phenomenon to which all the people have to adjust successfully, he admits that only some of them might have problems because of their type of nervous system, where the external stimuli might form disturbed conditioned reflexes by prolonged inhibitory reaction or by overexcitation. If the state is to carry out, successfully, social and philosophical education for almost all the people, it remains for the psychiatrist to continue the work of the state by shaping personalities.

In what way will psychotherapy help him? It is generally accepted that the purpose of psychotherapy is to influence by means of words the state of mind of the patient, thus making him accept society and integrate himself better into it. The difference between the Freudian and Pavlovian psychotherapeutic approaches is the difference in interpretation of conflict. According to Teplov,[13] behaviorist psychology is mechanistic because it interprets all psychological phenomena in physiological terms. Nevertheless, Watson asserts that there are subjective processes of human consciousness which cannot be studied by objective methods. Zalkind,[14] in trying to describe Freudian psychology, defines it as oriented toward the past. He goes on to say: "The past is at war with the present and is more powerful than the present. The conscious is subordinated to the unconscious. Man is preserved from the demands of society in a private little world in which he constitutes a special strategy of behavior. If the man is a pawn of internal elemental forces, what sort of result will we get?" Furthermore, he asks himself, how can we use the Freudian conception of man for socialist construction? The psychiatrist cannot allow the patient to sustain the idea of guilt by the unprofitable internal conflict of his own insight. The psychiatrist has "to quickly take people, socially open and easily collectivised, and completely transform their behavior," according to the general social directive. Psychotherapy will help him to reestablish the broken social conditioned reflexes by establishing a new verboverbal association, according to his type of nervous system.

Case 1.—A young male worker, 30 years of age, in good health, with a healthy background, was politically attached to the aims of the worker class.

He was without training except for seven years of elementary school and was promoted by the government after two years of political law school to a high social position as a judge. The tremendous responsibilities, with the difficult burdens of his occupation, had completely changed the life of the patient. He worked between 16 and 18 hours a day to keep up his social duties. After dealing with difficult justice problems, having to contend with the skill of lawyers, the pressure of the party, and the making of decisions, the patient started to present signs of anxiety, irritability, sweating, and precordial pressure. Over a period of two years, according to his complaints, he was seen at many medical services and was always considered as a cardiac neurotic.

At the time under discussion, while dealing with a difficult political, economic trial involving the lives of some innocent people, he started to doubt his abilities to give a right decision. He started the investigation two weeks previous to this trial, but he could not participate in any decision. The anxiety increased, he could not sleep well at night, and he began to experience feelings of foreboding that something terrible would have to happen to him. On the night prior to the trial, the patient, while reading papers presenting an accusation against some party members trapped by inexperience, identified with them and compared their situation with his, whereby he might be trapped by the lawyer. The patient became excited, with obsessional thought and hypnagogic hallucination. The patient was given a diagnosis of anxiety reaction, with a strong-unbalanced nervous system. The treatment was psychotherapy and sleep therapy to induce protective inhibition.

On looking into the patient's history, one finds that the change of his life from a manual to an intellectual worker increased the imbalance of the mechanism of cortical activity by excessively increasing the process of differentiation. Accordingly, he was advised to change his job to a less intellectual and theoretical one. The preferred procedure, in this case, was to soothe the conflict between him and the authority of the society represented by the party and to strengthen the socially conditioned constellation of motivation through other useful work with less excitatory differentiation processes.

To better understand the psychotherapeutic mechanism, it is necessary to again refer to the Pavlovian theory of motivation action. Human action is considered to be determined by any kind of status motive and directed toward a special goal. According to this conception all motives are derived from these needs, whether they are moral or material. The society holds all the aims in each structure, as well as the choice of those to whom permission to fulfill them might be given. The process of attaining the goal (being chosen) is directed by the social education with its special rules, established by the authority. In this condition, the action is determined by the conscious belief accepted by the society. It is a belief in the social structure of the state and the ability to arrive at a decision in accordance with the personal possibility. The role of the psychiatrist is to weigh the potentiality of the nervous system to support the social burden of the goal.

Case 2.—A woman, 28 years of age, was admitted to the hospital for a depressive reaction. The history indicated a normal childhood and adolescence. She successfully attended all the required schools and obtained a title as engineer. In college, she fell in love with an officer in the army. They were married, but at the end of the studies she was sent to a plant hundreds of miles from her home. As a matter of fact, not only was her marital life broken but even the love became doubtful. Under the new condition, she started to feel isolated and alone, at times presenting a spell of sadness. Her work, in her opinion, was not efficient and she was warned many times that she was a delayer of production. The place and the people were completely unfriendly to her and, even more, she missed the comfort of her home city. She could not give up the job because she might be sued by the state as a saboteur. Gradually, she lost any interest in life and wanted to commit suicide. When brought into the hospital, she was given a diagnosis of depressive reaction, with a weak type of nervous system.

The psychiatrist, by psychotherapy, worked to strengthen her social motivation above her personal and emotional needs by explaining that the conflict was caused by her weak nervous system and that the party could not trust this in any emergency. The social pressure was too strong to permit any deviation from the official line. Any fight to change position, city, or place of work is useless without official permission. She was taught to adjust herself to the need of the collectivity, to adapt to the new condition by solving the personal problem in accordance with the official requirements. The patient was cured.

Infancy and Childhood as Source of Neurosis

It is surprising to observe the lack of attention paid by the Pavlovians to infancy and childhood as a nucleus of later conflict and problems of adult neurosis. The psychological approach is limited to follow strictly the general pattern of education imposed by the state. The well-known conflict between the child and its parents has to be shifted to an abstraction—the collective authority. The long series of authority figures starts with different nurses in nursery homes and is continued with the teacher in kindergarten, elementary school, professional training, and so on, obtaining an impersonalized authority figure which helps the formation of the notion of symbolic authority. However, Pavlovians agree that the development of the personality is influenced by the social relationship in family life, education, and working collective.[12] According to them, childhood is a period in the life of the organism when, on the basis of the connection formed between organism and environment during phylogenesis, there is intensive building up of a structure of temporary connection that is acquired in the course of individual life.[15]

The individual at birth is under the influence of the environment in what he reacts to, with his anatomic-physiological nature and his innate interests. From the early motor and sensory activity of infancy, after the formation of the self-image, the child shifts gradually by developing his interests to the general and social meaning of the activity. Development is achieved by a process of imitation, as an expression of the unconditioned reflexes, and verboverbal nervous connection, as referred to the second system of signals.[16]

The early collective life, with its rigid taboos and obligations, completely changed and modeled the behavior and shaped the personality, according to the social concept. Therefore, the claims of the Russian psychiatrist and psychologist Rudik [17] about the typical new Soviet man who puts all his life in the service of the society, excluding his personal status motives, are not surprising. Even if their personal motivation is not excluded, they have to put in time in the interest of the state. Generally, this is the meaning of their Stakhanovism. Zachepitsky [18] agrees with the theory that neuroses are conditioned by psychic trauma, but the trauma is referred to early human social relations which might be in the early childhood.

The conflict could not be found in the childhood trauma of sexuality; the problem of the Oedipus complex is denied by the Russian psychiatrist as influencing the development of the individual, since the interest of the child, in that period, is directed toward the socialization of his needs. The solution of the sexual problem cannot represent a nucleus of the conflict, since relative sexual freedom helps the teen-ager to solve the problem. His interests and preoccupations are to cope with other dominant social needs and aims. The problem cannot represent a conflict for the patient if the society gives immediate, efficient, and harmless solutions. Therefore, all the efforts of the psychiatrist are directed to the dominant problem of the neurotic patient: to solve the social conflict of security.

Because the security of childhood is continued by social security, accorded by the state, the nucleus of the conflict is between the individual and the state and not in the individual-parent relationship. The state is entitled to affection, which is expressed by the individual through the quality and quantity of work done, and the state, consequently, gives security to the individual. The psychiatrist has to rework the process of socialization of personality in the light of the patient's nervous system. In reestablishing the socially conditioned reflexes, the psychotherapist uses the resources of mental activity of the patient but not of his unconscious. The Russian psychiatrist does not accept the idea of the unconscious as it is understood in the West.

This hypothesis is not accepted, but this does not mean, as many believe, that the Pavlovians do not accept the concept of forgotten repressed memory. They agree with the psychological materialistic theory of the amnestic mechanism of the forgotten memory. The memory represents all the past experiences obtained through perception. The perception reflects the object by the mechanism of the sensation, analyzed in the sensory cortical area and synthesized into the secondary or perceptal area. The memory represents its storage. It is influenced by the attention, which is based on induction of the psychological process of excitation and inhibition. The mneme has an affective color, which either will or will not help the process of recollection. Participation of the mneme in formation of the personality is through the process of learning and education, in other words, by experience. Therefore, it cannot constitute an element of unconscious conflict, since an unpleasant experience is not forgettable as an element of conflict, while a pleasant one might not be forgettable because of the importance of the experience to the patient. Repressed memories do enter in the formation of the stereotype reaction but cannot enter in the mechanism of the neurosis formation as a source of conflict, as long as they are forgotten experiences. At the moment of their reappearance as a part of the conflict, they are conscious. The process of neurosis formation remains an imbalance between overexcitation and the weak inhibitory process. The imbalance contributes to unbalanced stereotype reaction formed as a disequilibrium between their own demands and their resources. In this light, the duty of the psychiatrist is to look through the life history of the patient to study the imbalance between motivation and resource reality as a possible cause of the conflict. Accordingly, for example, hysteria is regarded as a condition which might appear in children for whom the environment has acted as a factor of too much excitation on the nervous system, regardless of whether their response is negative or positive.

Case 3.—The patient, a 27-year-old man with a bachelor's degree who had obtained a position as an employee in a plant, came to the hospital for paralysis of the right arm which appeared in the morning while going to work. The social history showed a cranky child who always did things in his own way and was very upset when he could not get what he wanted. In school he was an average student, obtaining many good marks fraudulently. He remembered an incident at the age of 15 when he fainted when he could not do a difficult task. Then he received attention and care which gave him a pleasant feeling. As a matter of fact, he repeated the same pattern of reaction whenever he could not solve his problems. (For instance, he fainted many times after he could not pass the examination to enter a university and was obliged to face life by working as an employee.) The conflict increased because his family always wanted him to have a brilliant career. The solution of the conflict was always found in his daydreaming. Going into the army, he had a hard time and spent a long time in the hospital for various sicknesses, more or less real. After the termination of his military service, he held various jobs until the last one. The unpleasant condition of the job appeared clear from his presentation. According to the law, he could not resign, and his hate against the job increased day by day. On the morning previous to the paralysis accident he had a conflict with his superior. He could not obtain a leave. The next morning he presented a paralysis of the arm, developed during the night.

The psychiatrist directed his work to reconstructing the personality according to the patient's real responsibilities in the social organization. His life was analyzed, point by point, showing him his inadequacy to cope with the situation of being promoted to a better position. The paralysis was treated as a syndrome with a short course, and healing was suggested as obligatory. Social motivation was emphasized in supporting the resolution of the conflict.

Comment

In conclusion, the psychotherapeutic work of the psychiatrist is to strengthen the social pattern established by the society and to look on the patient as an integral whole with a functional relation to the external factor activity. For the psychiatrist, the environment requires a particular dynamic character because the individual is in society which puts its seal on his development.

The psychiatrist and the patient, as products of the same society, have no other choice. The psychiatrist has to have a determined position in relation to pseudo-scientific manifestations of other ideologies. Even neutrality in the war against the other theory (Freud) is as contemptible and impossible as a tendency to compromise with it. A new orientation based on a nonmaterialistic philosophical doctrine means a mistake in science, and such a mistake is a political error.

This doctrine has to be satisfactory to the Pavlovians because it gives them the explanation of the creative processes which, according to Boico, are explained on the hypothesis of interaction of conditioned reflexes, a process that occurs partially as a result of spatial coincidences of excitation in the cerebral cortex cell. Different systems of connection function simultaneously and redistribute the nervous impulses entering the brain by forming, at a new qualitative level, the mental process.[16]

Summary

According to the Pavlovians, mental activity is a result of the function of the brain and is determined by the person's existence. Since it is mediated by the physiological mechanism, it has to be studied with the same materialistic methods, conceptualized by Pavlov. Since it is determined by the existence, it is influenced by the external world—society.

The psychotherapeutic approach has to be physiological and materialistic, philosophical and dialectical. It has to reestablish and reconstruct the broken socially conditioned reflexes by verboverbal associations to a certain type of nervous system. Any other approach, based on any nonmaterialistic philosophical, dialectical, and non-Pavlovian concept, is a scientific error.

DIHYDROSTREPTOMYCIN DEAFNESS

George E. Shambaugh Jr., M.D., Eugene L. Derlacki, M.D., Wiley H. Harrison, M.D., Chicago
Howard House, M.D., William House, M.D., Victor Hildyard, M.D., Los Angeles
Harold Schuknecht, M.D., Detroit
and
John J. Shea, M.D., Memphis, Tenn.

Cases of irreversible hearing loss attributable to dihydrostreptomycin are continuing to occur, usually without the knowledge of the prescribing physician, because of the latent period of from several weeks to as long as six months between administration of the drug and onset of the hearing loss. There is no known effective treatment for this type of nerve deafness. In view of the ototoxicity of dihydrostreptomycin and, in particular, in view of the unique latent period, this antibiotic should be omitted from commercial combinations of antibiotics or, if it is included, its presence should be clearly indicated in the name.

Four years ago attention was called[1] to the permanent deafness that may occur after administration of comparatively small doses of dihydrostreptomycin. Unfortunately, cases of irreversible hearing loss attributable to this antibiotic are continuing to occur, usually without the knowledge of the prescribing physician, because of the latent period of from several weeks to as long as six months between the administration of the drug and the onset of the hearing loss. This latent period is unique for dihydrostreptomycin. Other known ototoxic drugs, including quinine, streptomycin, neomycin sulfate, and kanamycin, produce an impairment of inner ear function usually immediately during or shortly after the time of administration.

The ototoxicity and the unique latent period before the onset of ear symptoms were first pointed out for dihydrostreptomycin in 1951 by Glorig,[2] who found that approximately one-third of a group of tuberculosis patients who received dihydrostreptomycin in doses of 2 to 7 Gm. weekly over a period of several weeks subsequently developed a hearing loss that began in some cases as late as five months after the medicament had been given.

Because of the known toxic effects of streptomycin on the vestibular function and the toxic effects of dihydrostreptomycin on the cochlear function, it was thought that by combining streptomycin and dihydrostreptomycin in equal parts the total dosage of each would be reduced and the undesirable vestibular and auditory toxic reactions would be eliminated.[3] What was first thought to be a logical therapeutic improvement has actually turned out to be an added danger, particularly when drug companies market multiple combinations of antibiotics combining penicillin, dihydrostreptomycin, and streptomycin under names that do not clearly indicate the presence of dihydrostreptomycin. In some cases injections of such combinations have been given not for severe infections as lifesaving measures but prophylactically in uninfected surgical patients or for mild common infections, and their administration has resulted in irreversible nerve deafness.

We have observed 32 cases of permanent hearing loss after the use of dihydrostreptomycin since the first report four years ago (see table). Additional cases of permanent hearing impairment, probably the results of administration of this drug but in which the total dosage or the exact preparation used was not known, have been encountered but are not included in this report. Cases 1-6 are from the office of Drs. H. House, W. House, and Hildyard; case 7 is from Dr. Schuknecht; cases 8-10 are from Dr. Shea; and the remaining cases were observed in the office practice of Drs. Shambaugh, Derlacki, and Harrison.

Summary of Thirty-two Cases of Dihydrostreptomycin Deafness

Case No.	Age, Yr.	Commercial Preparation Administered	Reason	Total Dose, Gm.	Time Before Onset of Hearing Loss After Drug Was Given, Mo.	Average Loss for Speech Frequencies, Db.
1	54	Dihydrostreptomycin	Cystitis	5	2 days	52, bilaterally
2	31	Dihydrostreptomycin	Influenza	3	2	40, bilaterally
3	65	Dihydrostreptomycin	Tuberculosis	60	During treatment	23, bilaterally
4	66	Dihydrostreptomycin	Tuberculosis	60	3	33, bilaterally
5	22	Combiotic	Influenza	1.5	3	35, bilaterally
6	65	Penicillin, Dihydrostreptomycin	Influenza	8	1½	80, right ear; 63, left ear
7	35	Dicrysticin	Tuberculosis	18	3	50, bilaterally
8	20	Combiotic	Cold	1	Immediately	35, bilaterally
9	40	Dihydrostreptomycin	Pleural effusion (smear positive for acid-fast bacteria)	15	2 (after last injection)	15, bilaterally
10	29	Dicrysticin	Bronchial asthma	2	Several	28, bilaterally
11	54	Neomycin, streptomycin-dihydrostreptomycin	Nephritis	6 4	3	30, bilaterally
12	51	Districillin	Panhysterectomy	18 cc.	4	25, bilaterally
13	41	Dihydrostreptomycin	Furuncles	2	1	42, bilaterally
14	70	Combiotic	Upper respiratory infection	3	5	50, bilaterally
15	64	Streptomycin-dihydrostreptomycin	Eye infection	7.5	4½	30, bilaterally
16	21	Dicrysticin	After appendectomy	2.5	5	30, bilaterally
17	29	Streptomycin-dihydrostreptomycin	Urinary infection	20	1	40, bilaterally
18	45	Combiotic	After hysterectomy	4	¾	57, bilaterally
19	39	Strocillin	After hysterectomy	8	3	37, bilaterally
20	54	Durycin	Pneumonia	6	4	50, right ear; 55, left ear
21	5	Streptomycin-dihydrostreptomycin	Meningitis, pulmonary tuberculosis	150 for 11 mo., 1 daily after	Indefinite	Total deafness
22	38	Combiotic	After appendectomy	3	2	48, right ear; 60, left ear
23	66	Strocillin	Urinary infection	17	5	30, bilaterally
24	45	Dihydrostreptomycin	Pneumonia, pneumonectomy	30	Time of therapy	85, bilaterally
25	16	Dihydrostreptomycin	Mononucleosis	30	4	20, bilaterally
26	31	Dihydrostreptomycin	Tuberculosis	100	6	88, right ear; 95, left ear
27	53	Dihydrostreptomycin	Sinusitis		Few days	60, right ear; 65, left ear
28	57	Dicrysticin	Bladder infection	14.5	3	50, bilaterally
29	46	Dihydrostreptomycin	Hernia, pneumonia	2	1	40, bilaterally
30	33	Streptomycin-dihydrostreptomycin	After appendectomy	21	¾	55, bilaterally
31	21		Encephalitis	14	4	30, bilaterally
32	29	Dihydrostreptomycin	Dry socket	7 injections	½	32, bilaterally

Report of Representative Cases

Case 18.—A woman, aged 45, with apparently normal hearing, was given eight doses of Combiotic (penicillin and dihydrostreptomycin) over four days as prophylactic therapy after an uneventful hysterectomy. The total dosage of dihydrostreptomycin was 4 Gm. Three weeks after the last injection of the antibiotics hearing loss was noted. The patient's hearing declined rapidly within the course of several days and then stabilized at the level shown in figure 1.

Case 19.—A woman, aged 39, had apparently normal hearing and received 16 doses of Strocillin (penicillin and dihydrostreptomycin) over an eight-day period after a hysterectomy. The total dosage of dihydrostreptomycin was 8 Gm. Tinnitus began 12 weeks afterward, and hearing loss was noted four months after the last dose. This patient was a telephone operator and became considerably disabled and depressed over her loss in hearing (fig. 1).

Case 28.—A man, 57 years of age, had cystitis and apparently normal hearing when he received over a two-week period Dicrysticin (procaine penicillin G, buffered crystalline sodium penicillin G, streptomycin, and dihydrostreptomycin) containing a total of 14 Gm. of dihydrostreptomycin. Hearing loss was noted within three months and became stable at the level shown in fig. 2.

Case 12.—A man, aged 41, suffering from furunculosis, had apparently normal hearing. He received four injections of dihydrostreptomycin, totaling 2 Gm., and noted hearing loss four weeks later (fig. 2).

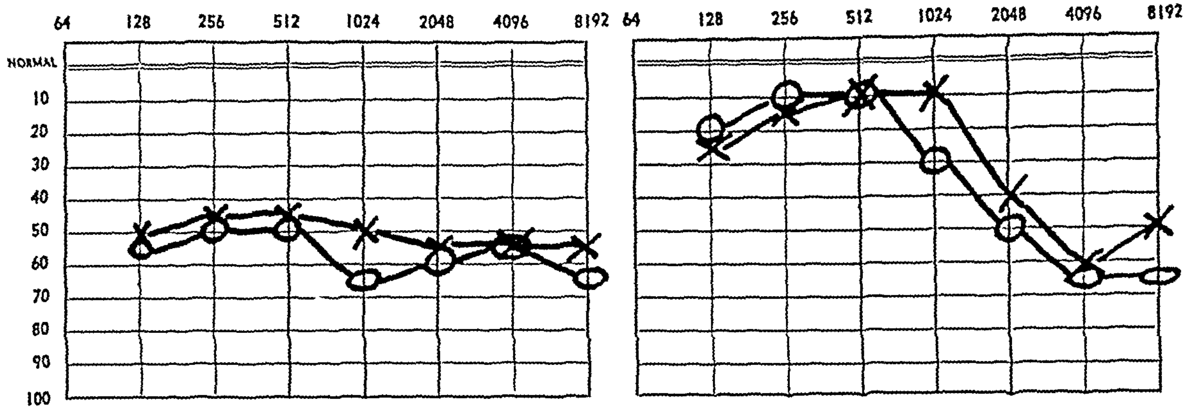

Fig. 1.—Results of hearing tests by air-conduction audiograms in cases 18 and 19. *Left*, case 18, audiogram showing loss for speech frequencies 512, 1,024, and 2,048 between 45 and 65 db. in both ears (*right ear, circles; left ear, crosses*), onset three weeks after receiving 4 Gm. of dihydrostreptomycin over four days. Discrimination score in right ear was 8% and in left ear, 18%. *Right*, case 19, audiogram showing loss for high frequencies greatest at 4,096 with discrimination score in right ear of 48% and in left ear of 72%, onset four months after receiving 8 Gm. of dihydrostreptomycin over eight days. (For good use of hearing aid discrimination score should be 90 to 100%. Score of less than 50% indicates great difficulty in understanding speech with or without hearing aid; score as low as 18% indicates that it is almost impossible for patient to understand speech by any means.)

Comment

Due to the latent period that frequently occurs between the administration of this antibiotic and the onset of the irreversible hearing impairment, dihydrostreptomycin is a particularly treacherous ototoxic drug. The small total doses of dihydrostreptomycin, 2 or 3 Gm., which effected permanent irreversible hearing loss in some of the patients observed (see cases 2, 5, 14, 22, and 29 in table), are noteworthy. In some cases the injections of the antibiotic, usually in combination with penicillin and streptomycin, were given not as lifesaving measures, but prophylactically in uninfected surgical patients or for mild, self-limiting infections such as influenza. The prescribing physician usually had not the remotest idea of the eventual disastrous results.

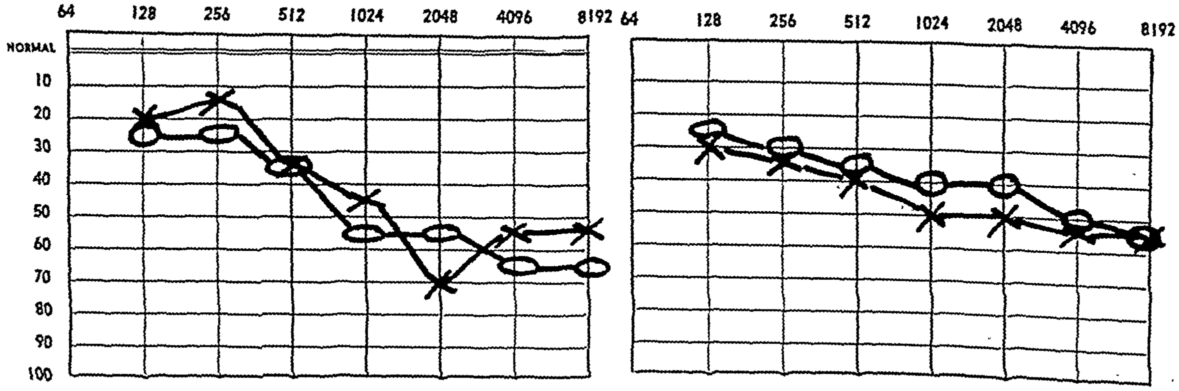

Fig. 2.—Results of air-conduction audiograms in cases 28 and 13. *Left*, case 28, showing loss of 35 to 70 db. for speech frequencies of 512, 1,024 and 2,048 in both ears, onset three months after administration of 14 Gm. of dihydrostreptomycin over 14 days. Discrimination score in right ear was 78% and in left ear, 40%. *Right*, case 13, audiogram showing loss of 35 to 50 db. in both ears, onset four weeks after administration of 2 Gm. of dihydrostreptomycin over four days. Discrimination score in right ear 74%, left ear 76%.

The typical hearing loss was one of high-frequency impairment, involving the lower frequencies to a lesser degree and varying with the dosage and the individual susceptibility. In many cases a mild or moderate hearing loss in the pure tone audiogram was accompanied by a disproportionate impairment of speech discrimination, so that the patient's ability to understand speech was more impaired than the pure tone loss would indicate and seriously affected or even prevented effective use of a hearing aid (fig. 1).

Such commercial preparations as Bicillimycin, Cillimycin, Combiotic, Crysdimycin, Dicrysticin, Dihydrocillin, Distrycillin, Durycin, SRD, and Strocillin* are mixtures containing dihydrostreptomycin, usually in combination with penicillin and streptomycin. All of these have been followed by permanent hearing loss in cases that we have observed.

There is no known effective treatment for this type of irreversible nerve deafness. The most that can be done for these patients is to make extensive trials with amplification of sound through hearing aids and instruction in lip reading to fill in the gaps missed by audition.

Because of its known ototoxicity, neomycin is now recommended for nonparenteral use except as a lifesaving measure. Kanamycin may soon be similarly restricted. In view of the less well-known ototoxicity of dihydrostreptomycin and, in particular, in view of the unique latent period before the onset of deafness, this antibiotic should be omitted from commercial combinations of antibiotics, or if included its presence should be clearly indicated in the name.

Since streptomycin is as effective as dihydrostreptomycin for gram-negative and acid-fast infections,[4] and since toxic reactions from streptomycin occur immediately and are more easily recognized and less permanently disabling, there seems to be little reason to use the more dangerous drug.

55 E. Washington St. (2) (Dr. Shambaugh).

This report was sponsored by the Committee on Conservation of Hearing of the American Academy of Ophthalmology and Otolaryngology.

FEEDING THE POTENTIALLY ALLERGIC CHILD.—A potentially allergic child is defined as one having one or more allergic parents or siblings. . . . Recent surveys show that in some instances as much as 25% of the pediatrician's time is spent in dealing with allergic children. Some of this increase is due to improved diagnostic awareness of allergy on the part of doctors but it is also due, among other things, to the marked decrease in breast feeding by our modern mothers. . . . Seven times more infants develop atopic dermatitis from cow's milk than breast milk and 80% of these infants later develop respiratory allergies. . . . There is active sensitization in utero. . . . Because the human placenta is permeable to the passage of undigested food antigen, large quantities of a highly allergenic food eaten in the last trimester may give rise to active sensitization of the fetus. The infant may then manifest symptoms on first ingesting that food. . . . The first step in the program of prevention starts with the mother during the last trimester. The mother should be allowed no egg or chocolate and one pint of cooked milk a day. . . . Vitamin D and calcium are given as supplemental therapy. The mother is to practise a diversified feeding program, particularly of sensitizing foods, by eating small amounts of a variety of foods. Food cravings should not be satisfied. . . . Food excesses tend to increase allergic manifestations. Excessive eating of seasonal foods produces some of our most severe reactions. Some of these coincide with our holidays, such as eggs at Easter and nuts at Christmas.—J. E. Stroh, M.D., and J. W. Georges, M.D., *British Columbia Medical Journal,* March, 1959.

CLINICAL NOTES

RESERPINE-INDUCED GASTROINTESTINAL HEMORRHAGE

Donald A. Duncan, M.D.
and
William Fleeson, M.D., Minneapolis

It is well recognized that reserpine, the crystalline alkaloid of Rauwolfia serpentina, can produce such undesirable effects as mental depression or Parkinsonism. An equally severe, but less well known, complication is acute upper gastrointestinal hemorrhage. Some patients in whom this has occurred have had a previous ulcer history,[1] whereas others have not.[2] Hollister [2a] reports hematemesis in a patient given 25 mg. of reserpine intramuscularly and 9 mg. orally over a five-day period. There had been no history suggesting peptic ulcer, and x-ray studies revealed only a hiatal hernia and enlarged rugae, no ulceration.

Lesser amounts for longer periods can produce the same results. Gailitis and co-workers [2b] describe three cases of acute gastrointestinal bleeding resulting from administration of 0.5 to 1.0 mg. of reserpine per day for 6 to 24 months in patients without any previous gastrointestinal disturbance. "Barium swallow" in two cases showed no pathology, but autopsy in the third disclosed acute hemorrhagic gastritis. The development of a duodenal ulcer the first time reserpine therapy is given is also well documented.[3] The present case is reported in order to emphasize the rapidity with which reserpine can produce gastrointestinal bleeding.

Report of a Case

A 59-year-old man was admitted to the University of Minnesota Hospitals for the first time on Feb. 20, 1959, for hereditary chronic progressive chorea with mental deterioration (Huntington's chorea) of five to six years' duration. His only other illness of significance was an episode of biliary colic in 1953 associated with a nonfunctioning gallbladder seen on x-ray. There was no suggestion of gastric or duodenal pathology.

Physical examination revealed a well-developed man with generalized choreiform movements, obvious mental deterioration, and hyperactive deep tendon reflexes. The blood pressure was 160/95 mm. Hg and the pulse rate 100 per minute. Laboratory studies showed a hemoglobin level of 16.7 Gm. per 100 ml. with normal urinalysis findings and white blood cell count.

In order to decrease the involuntary movements, treatment with reserpine was begun according to the schedule outlined by Lazarte and co-workers.[4] On Feb. 23 the patient received 5 mg. of reserpine intravenously at 3:30 p. m. and 2 mg. orally at 10 p. m. At 5 o'clock the next morning he awoke with epigastric pains and during the next three hours vomited 500 to 600 ml. of material containing large amounts of fresh and altered blood. The pulse rate stabilized at 100 per minute, and the lowest blood pressure recorded was 130/65 mm. Hg. The reserpine therapy was discontinued, and gastric suction and intravenous administration of fluids and 1 unit of whole blood were started. Throughout the day a marked cutaneous flushing and a generalized uncontrollable shivering were noted. The entire abdomen, especially the epigastrium, was painful and tender to palpation, and the intestinal sounds were normal to hyperactive. Thirty-four hours after the initial vomiting, coffee-ground material could still be aspirated but milk feedings were now tolerated.

On Feb. 27 an upper gastrointestinal series revealed only a small hiatal hernia; no ulceration could be seen. Further laboratory studies showed a normal bleeding time, Lee-White clotting time, platelet count, and clot retraction. The prothrombin time was 16.6 seconds as compared to a control of 14.1. The blood urea nitrogen level was 23 mg. per 100 ml., and liver function tests showed a total serum bilirubin level of 0.5 mg. per 100 ml., negative cephalin-cholesterol findings, thymol turbidity of 4 units, and sulfobromophthalein (Bromsulfalein) retention of 10% in 45 minutes. Several days later a repeat sulfobromophthalein test showed a retention of 8% and the blood urea nitrogen level had fallen to 18 mg. per 100 ml.

The patient was placed on a bland diet and did well with no evidence of further bleeding. On March 11 the hemoglobin level was 16 Gm. per 100 ml. and a guaiac test showed the stool to be free of blood. Chlorpromazine therapy appeared to decrease the hyperkinesis somewhat.

Comment

Stimulation of gastric secretion is believed to be an important factor in the ability of reserpine to produce ulceration of the stomach and duodenal mucosa. In man it was found that 1 mg. of reserpine given intravenously produced a marked hyperchlorhydria which began in 30 minutes, persisted at least four hours, and was the same in ulcer and nonulcer patients.[5] Rider and co-workers [6] demonstrated hyperchlorhydria with oral doses as small as 0.5 mg.

From the departments of medicine and psychiatry, University of Minnesota Medical Center.

Studies utilizing dogs with Heidenhain's pouches[7] or patients who have had vagotomy or vagotomy and sympathectomy[6] suggest that reserpine increases gastric secretion by a peripheral action on the parasympathetic ganglions located in the wall of the stomach. A direct action on the parietal cells cannot be excluded. Kirsner,[8] in his review of the subject, cites evidence that neither adrenocortical steroids nor serotonin appear to play a role. Whether histamine is a factor is undecided.

Khirwadkar[9] claims to have demonstrated a striking prolongation of the clotting time by reserpine, both in vivo and in vitro. On the other hand, Haverback and co-workers[10] found no significant alteration of the bleeding time, blood-coagulation mechanisms, or capillary fragility in patients given reserpine.

In conclusion, it is most improbable that gastrointestinal bleeding in patients taking reserpine is simply a fortuitous occurrence. Considering the large number of patients who have been treated with the drug, however, *it is not a frequent complication.*

Summary

A case of acute upper gastrointestinal hemorrhage occurred within 24 hours of initiation of therapy with reserpine. The amount that the patient received was relatively large—5 mg. intravenously and 2 mg. orally.

FOOTBALL INJURIES.—From 1947 through 1957, slightly more than 2000 injuries were observed among members of the football squad at Ohio State University. A series of 2000 injuries seems impressively large until we find that only 1 out of 3 was severe enough to cause the player to miss practice, and only 1 out of 80 required surgical correction. The surgical correction consisted primarily of suturing of lacerations, care of simple fractures, and splinting and casting of injured ligaments. Only a few major surgical procedures were required. . . . The time the members of the squad lost from school because of injuries was approximately equal to the time lost because of other illnesses. Similarly, the number of days spent in the hospital because of injury was approximately equal to, but somewhat less than, the number of days spent in the hospital because of illness. . . . In the 10 year period, 20 men were considered unfit to participate in football because of injuries, and 10 men were considered unfit for football because of medical reasons unrelated to injury. Of the 20 men ruled out of football because of injury, 8 had repeated minor head trauma and 6 had knee injury. . . . Minor head injuries are fairly common in football. Early return to play after a head injury often is followed by a repeated head injury. . . . Any head-injured player with prolonged unconsciousness or prolonged sequela or with any physical sign is hospitalized immediately for the usual observation and treatment. This type of head injury is rare in this 10 year experience. Only a few players have been hospitalized because of head injury, and only one had x-ray evidence of fracture. . . . The other potentially serious problem in football injuries is injury to the cervical spine. This occurs with the neck in flexion. It is extremely important that athletes be trained and conditioned to avoid flexion of the neck or ducking of the head while blocking, tackling or running.—R. Patton, M.D., Football Injuries in a "Big 10" University, *Postgraduate Medicine,* June, 1959.

CHOLESTASIS DUE TO PROCHLORPERAZINE

Albert Weinstein, M.D., Ben J. Alper, M.D., Nashville, Tenn.
and
James R. Dade, M.D., Hopkinsville, Ky.

During the past few years, jaundice has been reported rather frequently as a complication of several drugs of recent innovation, particularly those of the tranquilizer group. The clinical picture has been rather characteristic. The patient, when placed on therapy with the agent, in about 14 days develops fever, nausea, abdominal pain, muscle ache, and jaundice, in association with dark urine and light stools. The jaundice is usually gone within a few weeks but may continue for several months. Complete recovery is observed in most cases, but fatal agranulocytosis may occur. No particular treatment is indicated.

The laboratory data are those of an intrahepatic type of obstructive jaundice. The bilirubin level, particularly the direct fraction, is elevated, as are the alkaline phosphatase and cholesterol levels. There are no evidences of hepatocellular damage; cephalin flocculation is negative; and thymol turbidity, total serum protein level, and prothrombin time are all normal. The urine and stools contain both bile and urobilinogen. The histological picture in the liver is that of extrahepatic obstruction with bile stasis in the intracanalicular ducts, with periportal inflammatory cell infiltration in association with preservation of the normal lobular structure and with no evidence of hepatocellular damage or regeneration.

Although chlorpromazine is the chief offender among the tranquilizer drugs, arsphenamine, dinitrophenol, cinchophen, aurothioglucose, methyltestosterone, norethandrolone (Nilevar), thiouracil, para-aminosalicylic acid, sulfadiazine, and methimazole, also have been offenders.[1]

The result of a questionnaire [2] sent to 67 psychiatrists and mental hospitals is of interest. This inquiry on the occurrence of jaundice as a complication of the use of tranquilizing drugs indicated that among the 45 completed questionnaires 87 cases of jaundice had been reported. Available data indicate that 70 cases of chlorpromazine jaundice have occurred in about 15,000 patients treated. The sampled opinion suggested that the incidence of this complication was diminishing, perhaps as the result of greater caution in use of these drugs since it was first reported. In this inquiry three other phenothiazine derivatives were mentioned as offenders, namely, promazine (Sparine) hydrochloride, mepazine (Pacatal), and prochlorperazine (Compazine)—the latter in one instance only. There is, in the literature, only one actual report of jaundice as a complication of the use of prochlorperazine.[3] We now report another well-studied incidence of cholestasis following the use of this drug. This may help create an awareness of the possibility of cholestasis resulting from the use of this particular "tranquilizer." We wish to stress also the prognostic importance of fecal urobilinogen determinations during the course of this disorder.

Report of a Case

A woman, 49 years of age, was seen by one of us (J. R. D.) on Jan. 13, 1959. Results of the physical examination were negative. A history of recent nervous tension was elicited, and prochlorperazine, 5 mg., was given four times a day. This was the only medication received. After three weeks on this regimen she noted the onset of nausea, anorexia, and the development of a generalized pruritus. Her urine was observed to be very dark. She suspected there might be a relation between her medication and these symptoms, and she ceased taking prochlorperazine. A week later she had jaundice. At this time the direct bilirubin level was 4.75 mg. per 100 cc., and the indirect 1.47 mg. per 100 cc.

On admission to the Vanderbilt Hospital her jaundice was marked. There were no spider-type angiomas. The liver was just palpable, smooth, and moderately tender. The spleen was not palpable. There were no dilated veins over the abdominal wall, and no ascites. Results of the pelvic examination were negative. The thyroid was not palpable; no tumors were felt in either breast; the heart and lungs were normal.

The laboratory data were as follows: Urinalysis showed a pH of 5.5, a specific gravity of 1.025, occasional white blood cells, and was positive for bile and urobilinogen. The hematocrit was 44%; the white blood cell count was 7,775 per cubic millimeter, with differential count of 75% segmented forms. The sedimentation rate was 35 mm. per hour (Wintrobe) and the total eosinophil count 137 per cubic millimeter. The blood smear revealed normal numbers of red and white blood cells and platelets. The bleeding time was six minutes, the clotting time five minutes, and the clot retraction time two hours. The tourniquet test produced no

---

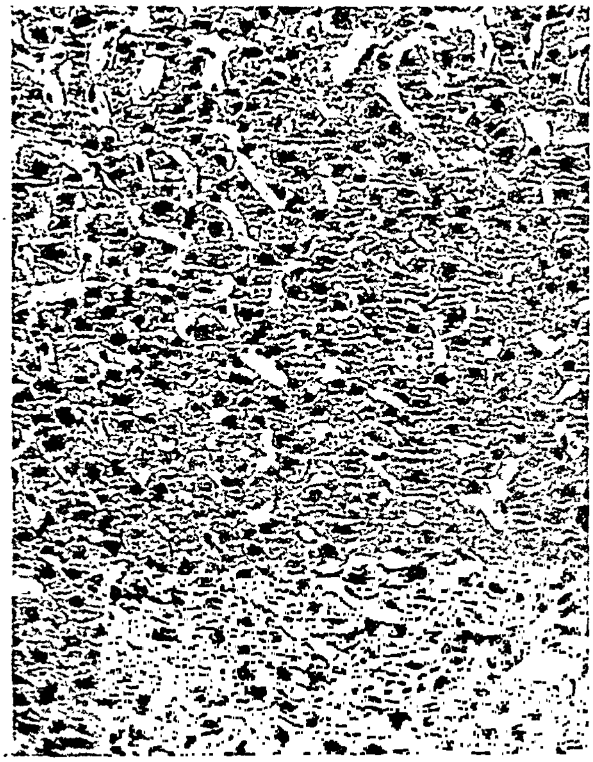
petechiae. Transaminase (serum) was 75 units. The nonprotein nitrogen level was 33 mg. per 100 cc., the blood sugar level 112 mg. per 100 cc., the serum protein level 6.7 Gm. per 100 cc., the albumin level 2.6 Gm. per 100 cc., the globulin level 2.6 Gm. per 100 cc., and alkaline phosphatase 7.1 Bodansky units. Cephalin flocculation was negative and thymol turbidity, 1 unit. The prothrombin time was 100% and the serum bilirubin level 1.9 mg. per 100 cc., direct, and 1.4 mg. per 100 cc., indirect. The cholesterol level was 350 mg. per 100 cc., and sulfobromophthalein (Bromsulfalein) · retention 37%. The stools were negative for blood, and urobilinogen was 260 Ehrlich units per 100 Gm. Heterophil agglutinations were negative. Values for the fragility test were as follows: initial hemolysis 0.33% NaCl, and complete hemolysis 0.30% NaCl. Chest x-ray, gallbladder series, gastrointestinal series, and electrocardiogram were all normal.



Liver aspiration biopsy, showing normal hepatocellular structure and evidence of cholestasis.

The patient was judged to have cholestasis due to prochlorperazine, and on March 14th a liver aspiration biopsy was performed by Dr. H. J. Shull. The biopsy revealed a characteristic pathological pattern of stasis in the biliary canaliculi without evidence of hepatocellular damage (see figure).

Her improvement was progressive, and the jaundice subsided promptly, as indicated in the table.

It was of considerable interest that the decrease in the bilirubin content of the serum was preceded by an observed increase in the quantitative fecal urobilinogen to 925 Ehrlich units per 100 Gm. This is confirmatory evidence of the mechanism for clearing the retained bilirubin, namely, by a mechanical overcoming of the cholestasis with discharge of the retained bilirubin into the biliary tract and consequently into the lumen of the intestine. There was never any indication of a hemolytic process.

Serum Bilirubin and Quantitative Fecal Levels Observed During Course of Treatment

Date	Serum Bilirubin Mg. per 100 Cc.		Fecal Urobilinogen, Ehrlich Units per 100 Gm.
	Direct	Indirect

3/21/59			260
3/23/59	0.3	0.5	
3/24/59	0.4	0.4	

Summary

A patient developed classic cholestasis while taking prochlorperazine (Compazine). The pathological diagnosis was established by a liver aspiration biopsy. The following points are significant: 1. This is the second reported incidence of this complication in association with the use of this particular drug. 2. Chloroperazine must be used with the same care and caution given chlorpromazine and other similar chemical agents. 3. The mechanism of clearing of the jaundice is related to a mechanical discharge of the retained bilirubin into the biliary tract and the intestinal lumen. This may be measured by quantitative fecal urobilinogen determinations. 4. Daily quantitative fecal urobilinogen studies are a useful method of following the progress of the cholestasis and help predict the course of the disease.

PULMONARY GRANULOMA DUE TO BRUCELLOSIS

Simon J. Ramah, M.D., Bernhard Chomet, M.D., James McLean, M.D.
and
Catherine Lemke, M.S., Chicago

Brucellosis has long been known to involve the lungs in varied forms. Haden and Kyger[1] reviewed several hundred case records of brucellosis of the lung and reported the findings of seven cases in detail. The latter included pleural effusion, pneumonia, hilar and bronchovascular infiltration, and also pulmonary granuloma. The diagnosis of pulmonary brucellosis was made on the basis of clinical characteristics, a positive brucellin skin test, and the exclusion of other disease. The causative agent was not recovered from any of the patients reported. Greer[2] in 1956 surveyed 59 cases diagnosed as pulmonary brucellosis. In his series the findings were those of perihilar and peribronchial infiltration, patchy pneumonia, pleural effusion, empyema, and single granuloma. The diagnosis of pulmonary brucellosis was based on the history and physical findings, blood cultures, and skin, agglutination, and opsonocytophagic tests.

In 1956 Weed and co-workers[3] reported three cases of chronic localized pulmonary brucellosis. One of these cases had been previously reported in 1952.[4] All three cases were characterized by well-defined densities of the lung on roentgenographic examination. These lesions were surgically removed, and each proved to be a caseous granuloma from which Brucella suis was isolated by culture. The purpose of this paper is to report another case of proved chronic localized pulmonary brucellosis.

Report of a Case

The patient, a 42-year-old longshoreman, entered the West Side Veterans Administration Hospital on Nov. 20, 1957, with the complaint of pain in the lower part of the chest on the left side for the preceding four weeks. Except for a slight fever and malaise at the onset with a mild productive cough the patient had no other symptoms. At the time of admission the patient was afebrile and his pulse was 110 per minute. Physical signs of pleural fluid were present on the lower left side of the chest. The blood value determinations showed a hemoglobin concentration of 12 Gm. per 100 cc., with hematocrit 39%, and a white blood cell count of 18,100 per cubic millimeter, with 83% polymorphonuclear leukocytes, 11% lymphocytes, and 5% monocytes. X-ray examination revealed a large collection of fluid in the left side of the chest. Five hundred cubic centimeters of cloudy purulent material was removed, from which hemolytic streptococcus was grown. Sputum cultures also revealed hemolytic streptococcus. A pleural needle biopsy specimen was diagnosed as inflammatory tissue. The patient was treated with penicillin, and later a rib resection was performed for drainage of an encapsulated empyema. The patient had an excellent response and was discharged from the hospital on Jan. 29, 1958, with the drainage completely subsided.

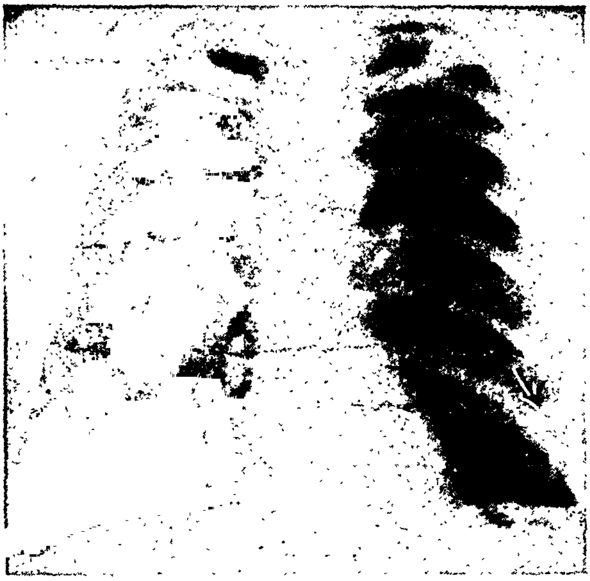

Fig. 1.—Roentgenogram made June 27, 1958, showing (*arrow*) nodular lesion of chest.

At the time of discharge from the hospital the chest x-ray still revealed considerable pleural thickening. He was examined at intervals and in March, 1958, a follow-up x-ray examination revealed a circumscribed density in the lower part of the left lung field. In June another film revealed the same well-defined round opacity, about 2 cm. in diameter (fig. 1). The density was thought to be in the lower lobe just below the major fissure. As the surrounding pleural reaction was subsiding the opacity became more evident. On July 25, 1958, persistence of the opacity was again observed roentgenographically. During this period the patient remained asymptomatic.

On Aug. 7, 1958, the patient was readmitted to the hospital. Results of coccidioidin, blastomycin, histoplasmin, and tuberculin skin tests were nega-

tive. On Aug. 12, 1958, a wedge resection of the left lower lobe was performed with the removal of a firm round nodular mass.

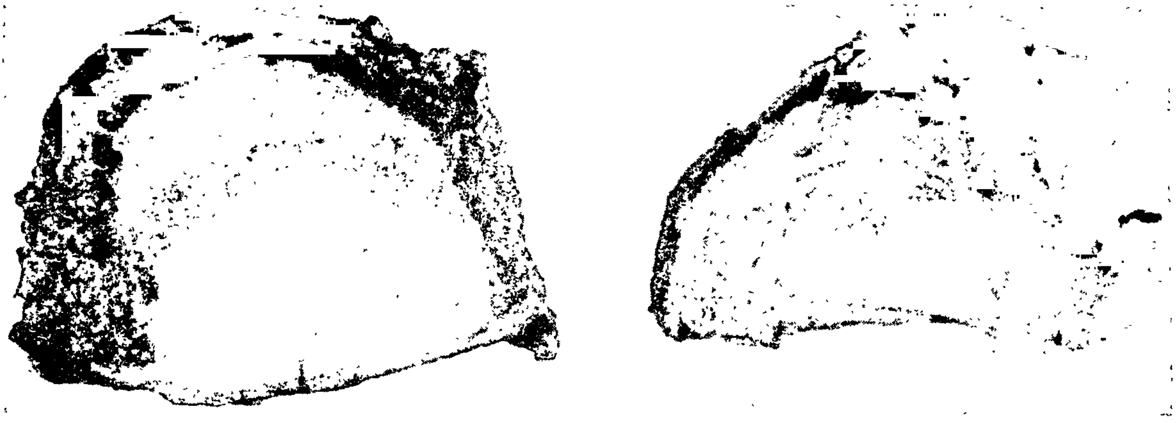

Fig. 2.—Cross section of resected nodule showing caseous necrosis and lamination.

Examination of a frozen section of the specimen revealed a granulomatous lesion. Gross examination of the removed mass showed lung tissue which was irregular in shape with a spherical firm nodule in its center. The latter measured 2 by 1.8 by 1.5 cm. The cut surface revealed a peripheral area of anthracosis and a central area of homogeneous firm white tissue with lamination and suggestive foci of calcification (fig. 2). Microscopic examination showed a large zone of caseous necrosis with hyalinization and focal calcification. At the periphery granulomatous inflammation was seen with an occasional giant cell (fig. 3). Stains for acid-fast bacilli and fungi gave negative results. Bacteriological study of the tissue showed Br. suis. Cultures for tuberculosis and fungi were negative. Results of Brucella agglutination tests done following surgery were negative on two occasions. The patient was discharged from the hospital on Sept. 3, 1958. He returned to his job as a longshoreman and has remained in excellent health.

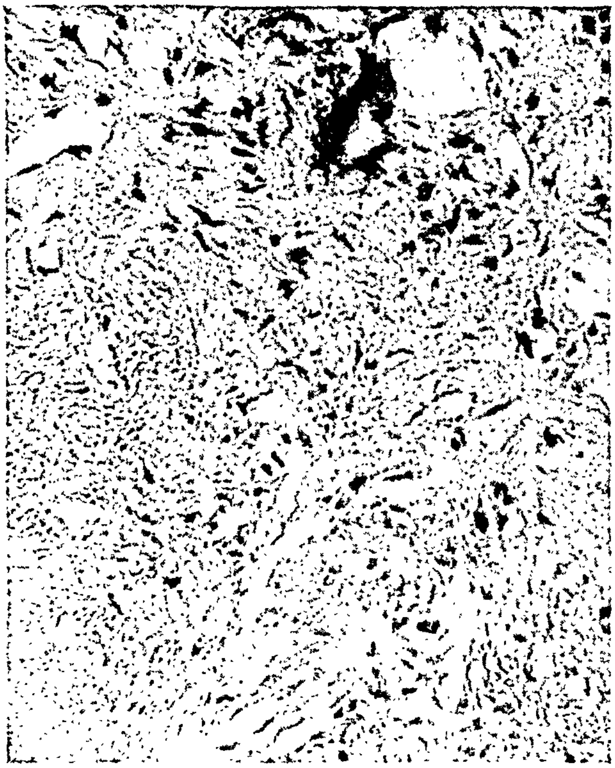

Fig. 3.—Microscopic section showing granulomatous inflammation with giant cells, and necrosis (×300).

Comment

We were impressed by the peculiar course of the disease in this patient. Originally an empyema was found, apparently caused by hemolytic streptococcus. After subsidence of the original infection the granulomatous lesion was discovered at x-ray examination. It is possible that the empyema was superimposed on an already present granulomatous lesion of the lung and that both processes had no relationship to each other. On the other hand, it is also feasible that this disease may have been a mixed infectious process with the streptococcus and Br. suis being the causative agents. However, this could not be proved since the previous culture was discarded after the hemolytic streptococcus was isolated. Quinn and Brown[5] reported a case of bacterial endocarditis with blood cultures positive for Br. abortus and alpha hemolytic streptococci (Streptococcus viridans).

As in the other three cases previously reported the diagnosis of Brucella granuloma was made only after bacteriological examination of the surgically removed tissues. It is coincidental to note that in these cases the causative organism was also Br. suis.

Weed and co-workers[4] have also emphasized the difficulty in establishing the diagnosis of offending organisms in chronic pulmonary infections and have pointed out that the majority of these lesions are caused by tubercle bacilli, fungi, or Brucella organisms. They also emphasized the difficulties encountered when histological findings alone are used to determine microbial etiology. Not infrequently the tissue reaction of brucellosis will simulate that of tuberculosis, and only bacteriological examination of the excised tissue will identify the causative organism.

The finding of granulomas in other organs than the lung has been recorded by various investigators. Barrett and Rickards[6] found granulomas due to brucellosis in the liver with focal calcification. Weed and co-workers[4] found noncaseous granulomas in the liver and hilar lymph nodes of the spleen in a case of brucellosis.

The negative results of the agglutination tests in our patient were not necessarily disturbing. As Weed and co-workers[1] pointed out, the granulomatous lesions are well encapsulated, thus keeping the antigen from the general circulation.

COMMITTEE ON TOXICOLOGY

The danger of suffocation presented by discarded polyethylene garment bags and plastic dry cleaning bags used as improvised mattress or pillow covers has been, until recently, generally unrecognized as an accidental hazard for infants and small children. Over a year ago, concern was expressed in Europe over the possible danger of suffocation of small children who placed plastic bags over their heads while playing; however, the hazards of plastic garment bags used as improvised mattress or pillow covers and the ominously increasing number of accidental deaths attributed to them has only recently received widespread attention in the United States.

The Committee on Toxicology became aware of the problem in January, 1959, on receipt of a medical society notice of four deaths from plastic bags in children in a one-week period in Phoenix, Ariz. As part of its environmental health activities, the Committee immediately forwarded notices to large metropolitan and national public health agencies. Nationwide attention was directed to the problem after a report in The Journal. *In the meantime, various public health groups initiated independent investigations and warnings. In particular, the National Safety Council undertook a survey of state health departments for accident statistics; local and state health departments alerted poison control activities and issued public warnings; the United States Public Health Service launched a nationwide epidemiologic investigation.*

The following paper is a status report of the progress which has been made in the evaluation of this public health problem.

Bernard E. Conley, Ph.D., *Secretary.*

DANGER OF SUFFOCATION FROM PLASTIC BAGS

A distressing number of deaths by suffocation have been reported since the original article in The Journal (169:2021 [April 25] 1959) called attention to the danger of allowing small children to play with plastic bags. Infants and young children have suffocated when they became ensnared in thin polyethylene film such as that used by dry cleaners for garment bags. It has been claimed that an electrostatic charge, generated by friction from handling, causes the film to cling tightly to the nose and mouth. The child, enmeshed in the clinging film, is unable to free himself and suffocates. Tragedies have occurred while children were playing with the bags, usually after the bags have been pulled over their heads, and reportedly as the result of using the plastic film as a makeshift pillow case, mattress cover, or blanket protector.

Because of the recent publicity on this unrecognized hazard, various public agencies have made surveys to determine the seriousness of the problem. A National Safety Council survey of 48 state health departments revealed 20 reported deaths in 10 states due to suffocation from plastic materials from January to March, 1959. Four states reported a total of nine deaths during 1958. However, for several reasons, these figures do not represent the full extent of injury. Of the states responding, some reported for only a two-month period, some were not able to decode their records for such detailed information, and, in a few instances, news reports of suffocation had not yet been included in the public records. The majority of reported deaths occurred in infants 6 months old or younger. In the 16 cases in which age was recorded, 15 deaths involved infants up to 6 months, and 1 death occurred in a child over one-year-old. Further analysis of the records showed that plastic sheets were mentioned in seven deaths and plastic pillow cases in three deaths. In six cases in which plastic sheets were mentioned, the mother had used them to cover the mattress in the infant's crib.

A United States Public Health Department survey of the first six months of 1959 disclosed 61 reported fatalities attributed to plastic bag suffocation, 80% of whom were infants. The use of plastic dry cleaner's bags as waterproof sheets for babies' beds was found to be the principal cause of death. Intensive investigation of the deaths, including autopsy findings, occurring in a one-month period, revealed suffocation to be due to mechanical causes rather than to sudden overwhelming infection which sometimes causes the death of infants.

At the time of this report, approximately 70 deaths attributed to plastic bag suffocation have been reported from official and unofficial sources. Ten of these were intentional deaths in adults. It now appears that the early estimate of 100 deaths for 1959 may be a conservative estimate, if the following remedial measures do not become effective.

Means for publicizing the hazard and warning parents about the misuse of plastic bags are being intensively studied by various groups including the American Medical Association, the National Institute of Drycleaning, the National Safety Council, the United States Public Health Service, and the Society of the Plastics Industry, Inc. The American Medical Association and the National Safety Council have broadcast warnings over radio and television, and these stations have donated free time for spot announcements at various intervals. A national advertising campaign to educate the public on dangers of misusing plastic bags has been undertaken by the plastics industry. The National Institute of Drycleaning sent special notices to its 8,600 members, urging them to warn customers against giving plastic bags to children to play with. The Society of the Plastics Industry, Inc., has prepared an educational folder which illustrates the hazards and cautions against the misuse of plastic film. Various manufacturers of plastic garment bags are supplying warning labels or modifying garment bags in order to provide a safer product for dry cleaning establishments and their customers.

Legislators have also shown their concern. Bills requiring warning labels on plastic bags have been introduced into Congress and various state and local legislatures. Attempts to prohibit the use of plastic materials for garment bags have been defeated in legislative bodies in preference to requirements for warning labels. A sense of perspective is needed until all facts about the problem, including current research as to the mechanics of its causes, are fully evaluated. Despite current publicity of the hazards to children, public preference for plastic garment bags still prevails.

Plastic film is a popular and useful material for packaging and for providing a protective covering. It is found in the home on a variety of household articles. Clothing and accessories such as sweaters, hats, and handbags are often sold encased in thin plastic bags; plastic bags are used to package produce, drugstore items, toys, sporting goods, and a number of other products; dry cleaners also use the plastic bags as protective covers for finished garments.

Despite the sudden awareness of the potential danger to infants and children, the convenience and utility which plastic offers as a covering material suggests that it will continue to be used. It is therefore imperative that parents take the following precautions:

1. Do not give plastic bags or plastic film in any form to children to play with.
2. After plastic bags and wrappers have served their purpose, destroy them.
3. Do not use plastic film as slip covers for pillows and mattresses or as blanket protectors.

Should an emergency arise from the misuse of plastic film, the following steps are recommended:

1. If the child's breathing has stopped, the immediate need is to restore breathing. If possible, call out a neighbor or send for help. Ask that a fire department inhalator squad be summoned and that the nearest hospital be alerted.
2. Try to resuscitate the child, using the mouth-to-mouth technique recommended as the most effective method by the American Red Cross:
   a. Place the child on his back and extend the neck back. Put a towel or pillow under the shoulders so the head drops back.
   b. Lift the lower jaw up to assure an open airway.
   c. Place your other hand on the stomach to prevent its overinflation.
   d. Place your mouth over the child's mouth and nose and blow in. After each breath, turn your head to the side, take another breath, and blow in again. Repeat 12 to 20 times a minute.
3. If the child is suffering labored breathing, is stunned, or has difficulty in movement, rush him to the nearest hospital.

COUNCIL ON DRUGS

NEW AND NONOFFICIAL DRUGS

The following descriptions of drugs are based on available evidence and do not in any case imply endorsement by the Council.

H. D. KAUTZ, M.D., *Secretary.*

Cadmium Sulfide (Capsebon).—CdS.

Actions and Uses.—Cadmium sulfide, introduced in 1958, is used for the treatment of seborrheic dermatitis of the scalp (seborrhea capitis). Most investigators consider it of about the same order of effectiveness as selenium sulfide, although some clinical reports indicate that selenium sulfide is slightly more efficacious. Thus, cadmium sulfide affords temporary relief of excessive oiliness, scaling, and pruritus in a large percentage of patients with this common dermatosis. It should not, in any sense, be considered a cure for the disease but, rather, a means of controlling the symptoms of seborrhea as long as it is periodically applied.

Under ordinary conditions of use, cadmium sulfide is essentially nontoxic. When instilled into the conjunctival sac of dogs, the drug is much less irritating than selenium sulfide; no instances of chemical keratitis or conjunctivitis have been reported after its clinical use. As with any topically applied agent, contact dermatitis may occasionally develop. However, the incidence of sensitivity reactions and primary irritation to cadmium sulfide is quite low. The drug does not appear to be absorbed to any appreciable extent from the intact skin, and there are no reports of systemic toxicity after its topical administration. Cadmium sulfide does not cause either rebound oiliness or dryness of the hair and, if thoroughly rinsed from the scalp, does not discolor white or gray hair. It is free from objectionable odors.

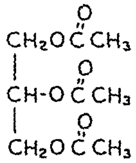
From the standpoint of safety and cosmetic acceptance, cadmium sulfide appears to compare favorably with selenium sulfide for the management of seborrheic dermatitis of the scalp.

Dosage.—Cadmium sulfide is administered topically in the form of a 1% suspension which is applied as a therapeutic shampoo. After wetting the scalp, 5 to 10 cc. of the suspension is applied by light massage to make a lather with which the hair is shampooed. After rinsing, the application is repeated. The second application should remain in contact with the scalp for 5 to 10 minutes and the head then thoroughly rinsed. For severe seborrhea, cadmium sulfide may be used every other day or twice weekly until improvement is noted. Thereafter, and in milder cases, weekly applications may be sufficient.

Preparations: suspension (topical) 1%.

Pitman-Moore Company, Division of Allied Laboratories, Inc., cooperated by furnishing scientific data to aid in the evaluation of cadmium sulfide.

Triacetin (Enzactin, Fungacetin).—Glyceryl triacetate.—The structural formula of triacetin may be represented as follows:



$$\begin{array}{l} CH_2O\overset{O}{\overset{\|}{C}}CH_3 \\ | \\ CH\text{-}O\overset{O}{\overset{\|}{C}}CH_3 \\ | \\ CH_2O\overset{O}{\overset{\|}{C}}CH_3 \end{array}$$

Actions and Uses.—Triacetin is an antimycotic agent introduced in 1956 for the topical treatment of superficial fungus infections of the skin. In concentrations of 0.1 to 0.25% it inhibits the growth, in vitro, of many of the species of Epidermophyton, Trichophyton, and Microsporum that commonly cause these infections; the more resistant Candida albicans is inhibited with higher concentrations. Its antifungal activity may be directly attributable to acetic acid, which is released from triacetin by a slow but sustained enzymatic hydrolysis by esterases. Such esterases, present in fungi themselves and also in human skin and serum, become inactive at a pH of about 4.0. Thus, the release of acid is self-limited and ceases when this degree of acidity has been produced. Attempts, in vitro, to induce resistance in fungi to triacetin have failed.

Although the antifungal activity of triacetin in vitro is well established, its effectiveness in vivo for the treatment of skin diseases caused by the aforementioned organisms has been questioned. It has been tried in infections caused by a variety of fungi involving the scalp, trunk, nails, groin, and feet. One clinician who has used the drug expresses the view that triacetin is of absolutely no value in these conditions; however, others apparently feel that it is of definite benefit, although its superiority to other drugs remains to be established. As with other fungistatic agents, tinea unguium responds only slowly, if at all. Triacetin has been employed, but without benefit, in blastomycosis of the skin. Results in superficial infections caused by C. albicans have been poor.

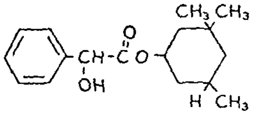
Triacetin does not irritate the skin. It has been applied to the ear canal and the vagina without ill-effect. In experimental studies, triacetin instilled into the conjunctival sac of rabbits daily for 15 days produced no evidence of conjunctival or corneal inflammation. Sensitization has not been reported. No effects attributable to systemic absorption after local application have appeared. It is odorless and stainless. The use of triacetin should be limited to the topical treatment of fungus infections of the skin. Although it produces little irritation, it probably should not be applied to acutely inflamed areas.

Dosage.—Triacetin is applied topically in concentrations of 25% or higher. Aerosols, ointments, powders, or solutions may be used. Methods and schedules of application do not differ significantly from those employed for other antifungal agents.

Preparations: aerosol (topical) 25%; ointment (topical) 25%; powder (topical) 33⅓%; liquid (topical) 30%.

Ayerst Laboratories, Division of American Home Products Corporation, cooperated by furnishing scientific data to aid in the evaluation of triacetin.

Cyclandelate (Cyclospasmol).—3,3,5-Trimethylcyclohexyl mandelate.—The structural formula of cyclandelate may be represented as follows:



Actions and Uses.—Cyclandelate, introduced in 1956, is an antispasmodic agent. Its action on smooth muscle closely resembles that of papaverine and may be classified as musculotropic, since there is assumed to be no specific biochemical antagonism to acetylcholine or to histamine. Spasmolytic activity has been demonstrated in vitro on a number of isolated tissues, including intestine, uterus, seminal vesicles, and gallbladder. It has about the same activity as papaverine toward spasm induced by the barium ion and slightly greater activity than papaverine toward that induced by histamine. It is only about 1/1,300 as active as atropine, however, in antagonizing acetylcholine-induced contractions. Cyclandelate partially suppresses the increased intestinal activity resulting from physostigmine injections, which may be considered evidence of antispasmodic activity in vivo. Several observations indicate that cyclandelate induces relaxation of vascular smooth muscle.

Studies on experimentally induced skeletal muscle necrosis and myocardial infarction indicate that, during the recovery period, the damaged areas are more vascular in animals treated with cyclandelate than in untreated animals. It is not clear whether this is due to vascular dilatation or to neoformation of blood vessels. Cyclandelate has no effect on cholesterol-induced atherosclerosis in rabbits. Oral administration in animals increases bleeding time but does not alter coagulation time.

In healthy human subjects, oral doses of 200 mg. of cyclandelate produce an increase in the digital sphygmic wave, total digital volume, and a slight but definite rise in skin temperature. The venous congestion test indicates an increase in flow per minute. Heart rate and blood pressure do not change appreciably. In normal subjects the effects of cyclandelate are detectable within 12 to 15 minutes after an oral dose, reach their maximum in about one and one-half hours, and have subsided within three hours.

Changes in obliterative vascular disease are qualitatively similar, but there may be considerable variation in the magnitude of the response from one patient to another. When studied in four patients with obliterative vascular disease who had been subjected to a unilateral lumbar gangliectomy, cyclandelate produced an increase in blood flow even in the denervated regions. The effects of a single dose in obliterative vascular disease may persist for four to six hours.

Early clinical reports of the use of cyclandelate in the treatment of peripheral vascular disease are favorable. Unfortunately, however, in the cases described, the patients were often subjected to other therapeutic measures as well, and true control observations were omitted. Cyclandelate is reported to have beneficial effects in obstructive vascular disease as well as in vasospastic conditions. Some investigators have reported better results in the former group of diseases than in the latter; this observation is difficult to explain. A varying percentage of patients with peripheral arteriosclerosis, diabetic angioses, thromboangiitis obliterans, acute thrombophlebitis, erythrocyanosis, local frostbite, Raynaud's disease, Raynaud's phenomenon, and vasospasm associated with neurological disorders have shown improvement after treatment with cyclandelate. Healing of refractory ulcers and relief of intermittent claudication are among the beneficial effects attributed to the drug. Results in acrocyanosis have been consistently poor.

Administration of cyclandelate to laboratory animals has produced no hematological abnormalities or other evidence of serious chronic toxicity.

Side-effects associated with clinical use of cyclandelate include flushing, tingling, dizziness, sweating, nausea, and headache. These are relatively infrequent at lower dose levels but occur in about one-third of the patients receiving total daily doses of 800 mg. or more. The sudden vasodilation, burning, and itching produced by nicotinic acid do not occur.

Cyclandelate may be used as an adjunctive agent in the treatment of peripheral vascular diseases. Although no vasodilator drug has proved consistently beneficial in these conditions, individual patients sometimes respond favorably. The relative efficacy of cyclandelate in comparison with other vasodilators is unknown, since there have been no systematic clinical investigations in which such a comparison was attempted.

Dosage.—Cyclandelate is administered orally. The usual dose is 100 mg. four times daily. Occasional patients may require larger doses, such as 200 mg. four times daily; in such instances annoying side-effects may occur, but they are usually mild and do not necessitate cessation of treatment.

Preparations: tablets 100 mg.

Ives-Cameron Company, Division of American Home Products Corporation, cooperated by furnishing scientific data to aid in the evaluation of cyclandelate.

COUNCIL ON FOODS AND NUTRITION

Report to the Council

The Council has authorized publication of the following report.

Philip L. White, Sc.D., *Secretary.*

EFFECT OF ALCOHOL ON THE LIVER

Gerald Klatskin, M.D., New Haven, Conn.

Alcohol is believed to play an important role in the pathogenesis of Laennec's cirrhosis and is known to potentiate the hepatotoxic effects of certain agents. Yet, paradoxically, in neither instance has it been established that alcohol exerts a direct effect on the liver. (In this report, the term alcohol refers to ethanol only.) The fact that alcohol has a caloric value of approximately 7 calories per gram and is capable of replacing isodynamic quantities of dietary carbohydrate in the support of growth[1] suggests that, in moderate amounts, it is a food rather than a poison. However, this does not exclude the possibility that, in excess, alcohol has a deleterious effect on the liver, as is the case with certain other foodstuffs. Indeed, the results of recent experimental studies[2] are consistent with this interpretation. The purpose of this report is to review briefly the evidence implicating alcohol as a factor in hepatic injury.

Relationship Between Chronic Alcoholism and Cirrhosis

The relationship between chronic alcoholism and cirrhosis has been recognized for over a century and is supported by autopsy evidence, indicating that the incidence of cirrhosis in alcoholics is at least six times as high as that in nonalcoholics and that the death rate from cirrhosis in many areas is closely correlated with the per capita consumption of alcoholic beverages.[3] Particularly impressive are the data showing the parallel decline in the death rates from chronic alcoholism and cirrhosis that occurred during the early years of the prohibition era in the United States.[4] Postmortem statistics probably underestimate the importance of alcohol as an etiological factor, since a reliable history of overindulgence may be difficult to obtain and often is omitted in clinical records and death certificates, particularly when cirrhosis is not the primary cause of death. This may account, at least in part, for the variable incidence of cirrhosis encountered in alcoholics examined post mortem, which has been reported to be as low as 1% in some series and as high as 25% in others.

On the basis of a careful appraisal of the autopsy data available in the literature up to 1941, Jolliffe and Jellinek[3] estimated that approximately 8% of chronic alcoholics ultimately develop cirrhosis. Even allowing for inaccuracies in the collection of these data, it is apparent that only a small fraction of heavy drinkers are subject to the disease. This suggests that there are differences in individual susceptibility to the effects of chronic alcoholism or that other associated factors play a significant role in the pathogenesis of cirrhosis. Although evidence bearing on the effects of malnutrition and other contributory factors is available in abundance, surprisingly little is known about the possible importance of differences in individual susceptibility. Unfortunately, the complexity of the exogenous factors to be considered is so great that it is not feasible to study this problem in man. However, it is noteworthy that in animal experiments, in which hereditary, environmental, and dietary factors are rigidly controlled, regimens designed to produce cirrhosis rarely affect all animals uniformly,[2] suggesting that endogenous factors may be important in determining whether or not cirrhosis develops.

Autopsy statistics on the incidence of chronic alcoholism in persons with cirrhosis show striking geographical differences.[5] To cite two extremes, the incidence was 86% in one series reported from Austria and only 2.5% in another reported from Turkey. Similar differences have been observed in various parts of the United States. Considering the multiplicity of factors that can give rise to cirrhosis, such differences are to be expected and reflect variations in the prevalence, not only of chronic alcoholism but also of other etiological factors in the populations selected for study. It is obvious, therefore, that, in evaluating the importance of alcohol as a factor in the pathogenesis of cirrhosis, greater weight must be given to the frequency with which chronic alcoholics develop cirrhosis than to the percentage of cirrhotic persons who are found to be alcoholic.

Despite the impressive body of evidence linking cirrhosis with chronic alcoholism, occasional investigators still question the relationship. An example is the relatively recent report of Voegtlin and his

---

From the Department of Internal Medicine, Yale University School of Medicine.

associates [6] based on a clinical and laboratory study of 300 chronic alcoholics "from the better classes of society." Although a significant number of their subjects showed functional and physical abnormalities pointing to liver disease, the authors concluded that, while chronic alcoholism often produces hepatic dysfunction and fatty infiltration, it does not predispose a person to the development of cirrhosis. This interpretation was based on the erroneous assumption that the cirrhotic process is always irreversible and progressive and that the hepatic dysfunction it produces invariably follows a characteristic pattern, features that were not observed in their series. It is noteworthy that similar clinical investigations of alcoholics, which have included histological examination of liver biopsy material, have invariably shown a significant incidence of cirrhosis.[7] This illustrates the fallacy of drawing conclusions regarding hepatic morphology from data based solely on clinical and functional studies.

Although the evidence cited clearly establishes that there is a relationship between chronic alcoholism and cirrhosis, it gives no indication of the mechanism involved. To elucidate this aspect of the problem, numerous attempts have been made to produce cirrhosis in animals by feeding them alcohol. Almost without exception such experiments have been unsuccessful.[8] However, it has been found that alcohol enhances the hepatotoxic effects of agents like carbon tetrachloride,[9] chloroform,[10] and phosphorus [11] and increases the severity of the cirrhosis produced by certain deficient diets.[12] Accordingly, it has been suggested that the effect of alcohol on the liver is always an indirect one. Early investigators proposed that alcoholic beverages contained toxic contaminants, such as copper [13] or phosphorus,[14] or produced gastrointestinal changes that permitted the absorption of endogenous toxins.[15] This view had to be abandoned for lack of supporting evidence. More recently, interest has shifted to the possibility that the effects of alcohol are secondary to a nutritional disturbance.

Dietary Factors

At the present time it is generally believed that the development of cirrhosis in chronic alcoholics is the direct consequence of the faulty dietary habits that often accompany habitual drinking. According to this theory an excess of alcohol, by providing a large number of calories and by depressing the appetite in other ways, leads to a reduction in the consumption of food, and particularly of protein, resulting in a deficiency of lipotropic substances. The latter comprise a group of compounds including choline, a constituent of phospholipid; the amino acid, methionine, which provides an exogenous source of labile methyl groups needed for the endogenous synthesis of choline; and folic acid and cyanocobalamin (vitamin B_{12}), which, in some species at least, are essential for the *de novo* synthesis of methyl groups. A deficiency of these substances in the diet of animals leads to fatty infiltration of the liver, which in most species is followed ultimately by the development of cirrhosis.[16] Recent evidence [17] indicates that the accumulation of fat under these circumstances may be related to a reduction in the rate of fatty acid oxidation.

What connection there is between the deposition of fat and the ultimate development of fibrosis is still uncertain. It has been suggested that (1) the presence of fat interferes with the normal metabolic activities of the hepatic cell, leading ultimately to its death; (2) distention of the parenchyma with fat obstructs sinusoidal blood flow, resulting in relative anoxemia and cellular necrosis; (3) the regenerative activity of the fat-filled cells is diminished, so that the normally rapid replacement of worn-out cells is hindered, permitting fibrosis to occur; and (4) adjacent fat-filled cells tend to merge, forming large cysts that ultimately rupture into the sinusoids and bile ducts, leaving behind a collapsed capsule of condensed reticulum. However, not all forms of experimental fatty infiltration of the liver give rise to fibrosis, and not infrequently in human cirrhosis there is a marked discrepancy between the extent and the distribution of the fat and that of connective tissue. This has led some investigators to conclude that the two lesions are not causally related.[18]

It is becoming increasingly evident that the effects of protein deficiency on the liver are not limited to those dependent on an inadequate supply of choline and its precursors. Animals fed proteins containing insufficient amounts of threonine, lysine, and tryptophan develop a characteristic type of periportal fatty infiltration that is not abolished by choline.[19] Low-protein diets produce, in addition to the fatty infiltration expected, degenerative changes and foci of necrosis in the parenchyma not seen in pure choline deficiency.[20] This probably accounts for the fact that protein supplements are more effective than choline or methionine in the repair of experimental nutritional cirrhosis [21] and may be of significance in the pathogenesis of Laennec's cirrhosis.

Although a great deal has been written about the importance of vitamins in the treatment of liver disease, there is no conclusive evidence to indicate that deficiency of any of the vitamins, with the possible exception of folic acid and vitamin B_{12}, which, as previously indicated, appear to play a role in choline synthesis, is a factor in the pathogenesis of nutritional cirrhosis. Experiments purporting to show a specific effect of other members of the vitamin B complex [22] have either been lacking in pair-fed controls to exclude effects dependent on differences in caloric intake and growth rate or have been complicated by other deficiencies.

Regarding the pathogenesis of Laennec's cirrhosis in chronic alcoholics, certain similarities to experimentally induced nutritional cirrhosis are at once apparent. Moreover, a number of observations may be cited in support of the concept that the disease is dependent on an alcohol-induced dietary deficiency of lipotropic substances. Thus, it has been demonstrated that there is a high incidence of malnutrition in chronic alcoholics with cirrhosis and that high-protein diets are therapeutically effective,[23] even in the face of continued alcohol consumption.[24] Also, biopsy studies indicate that, as in the choline-deficient rat, the cirrhotic process begins as a simple fatty infiltration of the liver that progresses to the stage of fibrosis and that protein supplements facilitate the removal of such fat and prevent further progression of the fibrotic process.[24]

At autopsy, the liver usually exhibits a uniform pattern of connective tissue septa encircling small regenerating nodules and isolated islands of surviving parenchymal cells with varying degrees of fatty infiltration and degeneration. These features are characteristic of Laennec's cirrhosis, which is a lesion known to occur not only in association with chronic alcoholism but also in a variety of other conditions, many of which are accompanied by malnutrition. Although fatty infiltration is generally considered to be an essential feature, it may be absent late in the disease as a consequence of progressive inanition or in any other stage of the disease as a result of treatment. In its most widely understood sense, the term Laennec's cirrhosis implies a lesion in which fatty infiltration, due to any one of a number of causes including chronic alcoholism and malnutrition, appears to be the forerunner, if not the immediate cause, of diffuse hepatic fibrosis and nodule formation. However, the term is used by some to indicate any type of cirrhosis characterized by a fine diffuse fibrosis with nodule formation and by others to denote a form of liver disease due specifically to chronic alcoholism and/or malnutrition. No doubt much of the disagreement over the relative importance of alcohol and other factors in the etiology of Laennec's cirrhosis stems from this confusion in terminology.

Occasionally, alcoholics develop a coarsely nodular type of cirrhosis that closely resembles the postnecrotic cirrhosis seen during the recovery phase of massive or subacute hepatic necrosis due to the hepatitis virus and certain toxic agents. The question arises whether the lesion in such cases is of nutritional origin or is due to causes unrelated to chronic alcoholism. It is possible to produce similar lesions in rats by rigidly limiting their intake of the sulfhydryl-containing amino acids, tocopherol and selenium.[25] It is doubtful, however, that these very specific dietary conditions have ever been duplicated in man. Moreover, it has not been established that the human liver is susceptible to massive necrosis under such conditions; therefore, on the basis of present evidence, it would appear more likely that the postnecrotic form of cirrhosis seen occasionally in alcoholics is due to coincidental factors unrelated to chronic alcoholism or malnutrition.

Judging from the evidence cited, there can be little doubt that nutritional factors play an important role in the pathogenesis of Laennec's cirrhosis. However, there are a number of observations that appear to be inconsistent with the generally accepted view that the effects of alcohol on the liver in man are due solely to the reduction in food consumption that often accompanies excessive drinking. These may be briefly summarized as follows: 1. Alcoholics occasionally develop cirrhosis despite an apparently adequate dietary intake; conversely, patients with sprue, anorexia nervosa, and a variety of other wasting diseases accompanied by severe malnutrition rarely do. 2. The inflammatory, necrotic, and degenerative changes, including the presence of Mallory hyaline bodies, so characteristic of active cirrhosis in the alcoholic, are not seen in experimental nutritional cirrhosis. 3. In contrast to the relatively benign character of the lesion in protein-deficient animals, the fatty infiltration and degenerative lesions that occur in the liver of chronic alcoholics occasionally give rise to overt hepatic failure and may cause death, even in the absence of hepatic fibrosis.[26] 4. Significant improvement in the clinical, functional, and histological status of the liver has been observed in persons with cirrhosis after withdrawal of alcohol and the administration of diets considered suboptimal by current therapeutic standards.[27] In short-term studies similar improvement has been observed in subjects receiving diets virtually devoid of protein. Discrepancies such as these suggest that the effects of alcohol on the liver may not be limited to those dependent on a reduction in food consumption.

Recent experimental studies indicate that, in the rat at least, alcohol tends to create a deficiency of choline by reducing the intake of food, by adding nonprotein calories to the diet, and by increasing the choline requirement via a mechanism independent of food consumption or caloric intake.[2] Since the administration of alcohol in such animals leads to an immediate decrease in food consumption that is calorically equivalent to the amount of alcohol ingested, this effect would appear to be a normal response to the homeostatic mechanism for the maintenance of a constant caloric intake rather than a manifestation of an alcohol-induced gastrointestinal disturbance leading to pathological anorexia. Assuming that the same mechanism is operative in man, this may account for the discrepancy between the inadequacy of the diet in many chronic alcoholics and their apparent failure to lose weight. Considering the fact that a heavy drinker may consume between 1,000 and 2,000 calories a day in the form of alcohol, it is not surprising that he is able to maintain his weight and satisfy his appetite, despite a dwindling food intake. Obviously, the maintenance of an adequate caloric intake under such circumstances is made at the expense of essential nutriments, including proteins and vitamins, so that specific nutritional deficiencies may develop despite the absence of weight loss. However, long-continued drinking ultimately produces a pathological type of anorexia that leads to a reduction in total caloric intake and overt signs of undernutrition.

The experiments cited have established the important principle that the choline requirement varies directly with the caloric intake. Hence, if the diet is marginal in lipotropic activity, the mere addition of nonprotein calories, whether they be derived from alcohol or from carbohydrate, will induce a relative deficiency of choline. This may be one of reasons why cirrhosis is more common in alcoholics than in patients with chronic wasting diseases, in whom the diet may be equally deficient in protein, but whose caloric intake is significantly lower. Also noteworthy in this connection is the fact that in areas of the world where cirrhosis of presumed nutritional origin is prevalent, the native diet is deficient in protein but usually contains an abundance of calories in the form of carbohydrate.

Under appropriately controlled conditions it can be demonstrated that, in the rat at least, alcohol increases the choline requirement in still another way unrelated to changes in food consumption or the caloric intake.[2a] Quantitatively this effect appears to be even more important than the others. Nothing is known about the mechanism involved, but it has been suggested [28] that choline may be a factor in the metabolism of acetyl coenzyme A and, hence, may be required in greater amounts when alcohol is oxidized to acetate.

It is important to bear in mind that the increase in the choline requirement induced by alcohol cannot be demonstrated experimentally unless the diet is marginal in its content of lipotropic substances, resulting in an overt deficiency. This suggests that the alcohol effect is readily abolished by small amounts of protein or choline in excess of the minimum required to maintain the fat content of the liver at a normal level. This fact has been confirmed experimentally,[2a] which probably accounts for the observation that alcohol has no deleterious effects on the liver when administered to persons with cirrhosis receiving a high-protein diet.[24]

Recently it has been reported that cirrhotic persons with a daily protein intake of as little as 25 to 65 Gm. suffered no ill-effects when given alcohol in amounts equivalent to one-half pint of whiskey daily for two to four weeks.[29] Indeed, the authors were so impressed with the salutary effects of alcohol on the mental status and appetite of their patients that they endorsed its use in the treatment of alcoholics with cirrhosis!

This type of study is difficult to interpret and does not necessarily establish that alcohol is innocuous in chronic alcoholics with cirrhosis. First, six of the seven patients studied were not investigated until icterus or ascites, or both, had improved, presumably as a result of treatment. This raises a question regarding the possible sustained effects of protein stored during this preliminary period. Second, although liver function and morphology either improved or showed no change, the possibility that the rate of improvement was slowed or delayed was not excluded, particularly since no data are given on the rate of recovery before the experiment was started. Third, no account is taken of the possible benefits derived from the decrease in physical activity imposed by hospitalization, a factor that could conceivably have obscured the effects of alcohol. Fourth, five of the subjects received 60 to 65 Gm. of protein daily, an amount adequate to promote recovery in most cirrhotics,[27] and possibly significantly in excess of the minimum required to obscure the effects of alcohol. Fifth, the authors state that, at the beginning of the experiment, anorexia was so severe that it was difficult to maintain a constant intake of food but that there was rapid improvement when alcohol was administered. In the absence of any data to the contrary, this suggests that the protein intake may have increased, thus protecting the patient against the alcohol effect. Finally, in subjects drinking the amounts of alcohol used in this experiment, signs of liver disease, whether they be due to nutritional or other factors, do not appear for a number of years, so that the period of observation of two to four weeks may have been inadequate.

Enzymatic Activities of the Liver

In addition to the changes alcohol may evoke by inducing a nutritional deficiency, it may affect the liver in other subtle ways. One of these relates to its possible interference with some of the enzymatic activities of the liver. It has been demonstrated that, in yeast suspensions, alcohol blocks the reduction of the cytochromes, a group of important iron-containing cytoplasmic heme proteins that serve an essential role as electron carriers in the complicated chain of enzymatic reactions involved in oxidation.[30] Similarly, it has been reported that alcohol may reduce the activity of the citric acid cycle in the liver.[31] The evidence for this is the observation that, after the administration of alcohol, there is an increase in the lactate and acetate and a decrease in the pyruvate, alpha-ketoglutarate, and citrate content of the hepatic venous blood.

In its oxidation alcohol undergoes rapid successive dehydrogenations to acetaldehyde and acetate, enzymatic reactions involving the transfer of hydrogen and electrons via the coenzyme diphosphopyridine nucleotide (DPN), which serves as a carrier and is reduced in the process. In the report cited the author suggests that pyruvic acid is the hydrogen acceptor in this reaction yielding lactic acid and that the activity of the citric acid cycle in the liver may be depressed temporarily as a consequence of the rapid removal of pyruvic acid and the accumulation of reduced DPN.[31] Moreover, he postulates that this may reduce the amount of adenosinetriphosphate (ATP) generated in the cycle; hence, it may inhibit ATP-dependent enzymatic reactions, which over a prolonged period might result in a cellular injury. Recently the activity of still another enzyme in the liver, glutamic pyruvic transaminase, has been found to be decreased under the influence of alcohol.[32] The aforementioned enzymatic defects do not necessarily constitute a complete inventory of all those that may occur. Since this aspect of the alcohol problem has received scant attention, further investigation may reveal other abnormalities of equal or even greater importance. Whether or not alcohol-induced aberrations in enzyme activity play a role in the pathogenesis of liver disease is still problematical. Nevertheless, these observations suggest new avenues of investigation and illustrate the important point that, in the metabolism of an apparently innocuous substance like alcohol, there may be unexpected and possibly deleterious side-effects.

Possible Role of Infection

Certain features of the cirrhosis encountered in chronic alcoholics are not readily explained on the basis of a nutritional or metabolic defect and are not reproducible in experimental animals maintained on deficient diets and a high intake of alcohol. Of particular interest in this connection are the manifestations exhibited in the florid form of the disease.[33] These include a progressive downhill course, signs of hepatic failure that are refractory to dietary and other forms of treatment, and the presence in the liver of extensive necrotic, degenerative, and inflammatory lesions engrafted on an underlying fatty infiltration and/or cirrhosis. Usually the onset is insidious after a prolonged period of heavy drinking and dietary restriction, but occasionally it is acute.

Although fever and leukocytosis are common, overt signs of intercurrent extrahepatic infection are unusual. The features described suggest the possibility that the liver itself may be the site of infection. Occasionally bacteria have been demonstrated in the liver [34] and blood [35] of such patients. However, the more frequent finding of negative cultures and the ineffectiveness of antibiotic therapy in most cases of florid cirrhosis make it unlikely that bacterial infections play an important role in this disease. Moreover, it is highly probable that the occasional occurrence of bacteria in the liver is the consequence rather than the cause of the underlying hepatic disease and is indicative of a breakdown of the important defense mechanism in the liver for the destruction of organisms that gain access to the blood.

Another more interesting possibility is that the hepatitis virus is implicated, and that chronic alcoholism either increases the susceptibility to intercurrent infections or activates latent infections in carriers. Admittedly, the lesions in florid cirrhosis do not resemble those of classic acute vital hepatitis. However, the possibility cannot be excluded that the presence of antecedent hepatic injury related to chronic alcoholism modifies the morphologic manifestations of such infections. Unfortunately, no attempts have been made to demonstrate the virus in alcoholics with cirrhosis by means of human transmission experiments, the only method available at the present time. However, it is noteworthy that, in an investigation of apparently healthy blood donors thought to be responsible for hepatitis infections in recipients, four of the five who proved to be carriers by transmission experiment were excessive drinkers, and three investigated by liver biopsy showed either cirrhosis or less extensive hepatic fibrosis and inflammation.[36] Obviously, further studies of this type are needed to establish whether or not the hepatitis virus is responsible for any of the clinical or pathological manifestations of cirrhosis in alcoholics.

As previously noted, the old theory, that the absorption of toxins from the gastrointestinal tract under the influence of alcohol is a factor in the pathogenesis of cirrhosis, had to be abandoned for lack of supporting evidence. However, it has been revived as a consequence of recent reports indicating that broad-spectrum antibiotics which suppress the intestinal flora delay the appearance of hepatic necrosis in animals maintained on necrogenic diets [37] and prevent the development of hepatic fibrosis in choline-deficient animals.[38] As provocative as these observations are, they do not prove that toxic substances from the intestinal tract injure the liver, since in neither of these experiments was the possibility excluded that the antibiotics used contained a protective factor or that suppression of the intestinal flora deprived the animal of protective substances of bacterial origin.

Summary

A review of the evidence indicates that chronic alcoholism is an important, but by no means the only, etiological factor in the pathogenesis of Laennec's cirrhosis and that, whereas the malnutrition associated with excessive drinking undoubtedly accounts for many of the effects of alcohol on the liver, other as yet unidentified mechanisms may be involved.

Story of Tao Koo

Author and physician Thomas A. Dooley, from his "little hospital on stilts" in the northern mountains of Laos, recounts this tale of compassion and survival:

"A 7-year-old tribes-boy named Tao Koo had a scorching fever and diarrhea. Within two weeks the child developed a bed sore. Within a month this had spread until all the flesh from his lower back and buttocks had sloughed off. He shrank and withered until he was just the shadow of a child. Finally the father brought him to us in Muong Sing, a three-day walk.

"Earl Rhine and Dwight Davis [Dr. Dooley's assistants] immediately took that little urinoid glob of flesh and washed him with all the tenderness they could muster. With the hearts of men, the hands of women, and a little of the mystery of God they gently scrubbed his sores, treated and dressed them. They rigged a special bed for him, tying balloons across the cross-bars. They pasted pictures to the wall alongside it. They gave him a coloring book and a squeaking rabbit.

"On the few days that we have sunlight they bring his bed outside. The dressings are removed. This wistful little lad, God's compromise between flower and dung, an interval between birth and death, once again began to live. He began to smile. Sores are closing up. He is happy."

For a view of medicine on the other side of the bamboo curtain, see p. 1685.

Rural Attack on Aging—A First Step

Doctors Provide the Spark That Sets a Town to Thinking

Big cities may be the heart of a nation, but it is in the vast throb of rural America that the complex problem of aging pulsates as a personal matter. Here there is no hustle and bustle of a concentrated population to engulf that problem as one of many—perhaps to shelve it dispassionately. The following report shows a neighbor-to-neighbor concern for the difficulties encountered when, say, one small-industry worker retires, or when a graying farmer no longer can take the daily routine of managing a dairy herd.

In facilities for the aged Wisconsin's Fond du Lac County (pop. 75,000) is probably more fortunate than most rural areas. Two religious groups operate homes for the elderly, and the entire area takes pride in the brand-new county home. There are also two proprietary nursing homes.

But the residents of Fond du Lac County know it takes more than institutions to ease the pressures generated by a rapidly expanding segment of elderly citizens. Yes, you would expect to find ministers acquainted with the needs and hopes of the elderly, but this same familiarity also extends to the slender and sprightly manager of the telephone exchange, to the friendly but reserved president of one of its banks, and to the community's teachers, attorneys, and clubwomen.

This awareness is no accident. Fond du Lac's people have all the usual human regard for the problems of a neighbor, but it took positive action by the county medical society to acquaint them with the unlimited challenge of caring for their oldsters and to offer a forum for the ideas and opinions of others.

Banker, physician, businessman: Rural Fond du Lac County in Wisconsin hopes to improve the lot of its aged through widespread cooperative effort. From left are W. A. Sanders, Dr. A. M. Hutter, and O. C. Claus.

That forum was called a Community Roundtable Conference, and neither the snow nor the cold of a day last December kept businessmen and labor leaders, nurses and hospital administra-

Three-Way Split

Nursing-home facilities for Wisconsin's chronically ill and aged are almost equally divided among proprietary, nonprofit, and governmental operation, according to the Division on Aging of the State Medical Society of Wisconsin.

In 1958, with a total of 18,129 residing in these homes, 38% were cared for in proprietary facilities, 30% in nonprofit homes, and 32% in governmental institutions.

tors, physicians and attorneys, and welfare workers and clergymen from attending.

Enthusiasm for the project radiates from Dr. A. M. Hutter, a Fond du Lac internist and chairman of the county society's committee on aging, as he sits at his desk and tells you about it. On the wall is a wartime photograph of himself in Naval uniform standing self-consciously beside a Yule-decorated dispensary refrigerator bearing a large sign emblazoned "Dr. Hutter's Penicillin Tree."

"Those people were not only ready for us," he says, "in some cases they were way ahead of us. I opened the conference with an outline of some of the basic medical and psychological problems faced by many of our elderly people. Then the other fellows told of the kind of thing they meet up with in treating the aged."

The "other fellows" are four local colleagues—Dr. D. W. McCormick, an orthopedic surgeon; Dr. H. K. Gugh, a urologist; Dr. James Habermann, a general practitioner; and Dr. William Wojta, an ophthalmologist.

At First—Hesitation

As the professional men finish, lay participants tell the conference what they know of the difficulties encountered by older people, and of some of the successes and failures that have marked efforts to help.

Some are hesitant at first. Among them is O. C. Claus, district manager in Fond du Lac for the Wisconsin Telephone Company. But, as he listens, Claus comes to realize that a program with which he has an intimate connection is a perfect case in point.

As a veteran employee of the phone company, Claus became eligible, after 21 years of service, to join a nationwide organization known as the Telephone Pioneers (see Medicine at Work, The Journal, March 21, 1959). Claus did join and immersed himself in the fellowship of the group. Later, as head of the local chapter, he became disturbed by the obvious difficulties of some of the men when it came time for their retirement. Not too far from retirement himself, he decided the Pioneers could help.

Under his direction a new subdivision of the group was formed. Called the Life Member Club, it is open to all retired telephone employees. Claus says, "They meet once a month in the conference room here at the office. After the meeting they go downtown for lunch. Each man pays for his own, too, and they have a pretty good time."

Although the group got off to a mild beginning even Claus is surprised by the momentum it has picked up. "First they decided to have a Christmas party. They planned it carefully and put it on themselves. When it turned out to be a success, they decided to take on more projects. The next thing was a picnic and right now it's a hobby show that is going to be held right here in the building. It's surprising how even a minor sort of activity like this adds purpose to life, once you've retired."

Frame of Reference

Others view the difficulties of aging in terms of their own experience. Two clergymen—Father Henry Maurer of St. Mary's Catholic church, and Rev. Karl Koehler of the Evangelical and Reformed Church of Peace—stress the importance of religious life to the aged. At the Community Roundtable Conference last December they urged the establishment of church-sponsored social groups for the aged and expressed the conviction that peace of mind and heart are especially necessary to the well-being of the elderly person.

True, all this interest and concern has not really solved anything yet in Fond du Lac County. No revolution in community thinking has yet taken place. No well-rounded, carefully planned, multiphased approach to the many needs of the county's aged has yet appeared. But Dr. Hutter feels today that an important beginning has been made. He calls the Roundtable Conference a success and advocates extension of the idea. He says, "The big need now is for education in this field—education and leadership. We've got to educate our people to the nature and extent of the problems faced by those over 65, and we have to educate our physicians to assume roles of leadership in their own communities."

If any physician in Wisconsin is in a position to do this it is Dr. Hutter, who wears two hats in the field of aging. He not only is chairman of the Fond du Lac County medical society's committee on aging, but he also heads the Aging Division of the State Medical Society of Wisconsin. And it is significant that, having tested the idea on his home ground, Dr. Hutter recommends the

Community Roundtable Conference as a good device for organizing interest in the problems of oldsters in any area.

What is next in Fond du Lac's effort to aid the aging? Well, if county chairman Hutter takes the advice of state chairman Hutter, it might be any one of a number of things—speaker services for schools, development of a retirement-preparation program for industry, or a countywide survey of the needs, services, and facilities for aging and long-term patients.

Medical societies in two other counties, Dane and Sheboygan, have already accepted the survey suggestion. Working with their respective welfare councils, the societies have guided county residents in comprehensive studies of this type.

Other Places, Other Things

Medical societies in other parts of Wisconsin, urged by the state society's Division on Aging, have also attempted programs of their own:

—The Brown County medical society is giving support to a community project in Green Bay to improve the lot of the chronically ill in nursing homes.

—The Racine County medical society is providing medical personnel to conduct preretirement programs for industries located in its area.

—The Marathon County medical society sponsors radio and television programs on the subject of aging for listeners and viewers in or near Wausau.

Dr. Hutter thinks those interested in helping the aged may be unintentionally scaring off prospective stalwarts by the introduction that many of them get. He says, "Don't start off by taking them on a tour of the geriatrics ward of the local hospital, because they'll only see patients who never had a chance at rehabilitation. Those patients do need good care and deserve it, but the long-range solution is to train the younger person for old age—to understand diet, positive health measures, and freedom from emotional conflict."

Some measure of the increasing awareness of broadly human needs of the elderly in Fond du Lac County is indicated by the feelings of two businessmen. Listen to Mr. W. A. Sanders, president of the National Exchange Bank: "It comes as a jolt when we comprehend what it really means when we say that almost 10% of the people in Wisconsin today are 65 or over."

Or Mr. Claus of the telephone company: "It isn't enough to give a man a party, a pension, a pat on the back, and best wishes for a long and happy life. A man needs to feel he isn't being cut off from the people with whom he's spent a big part of his life."

Rx for Housing

Three ways to help elderly persons finance adequate housing without using any new form of government help have been suggested by a New York banker. Speaking to physicians and other participants at the University of Michigan's 12th annual Conference on Aging, June 23, Harry Held made these proposals:

1. Offer life and health insurance programs to the elderly which would insure their ability to make mortgage payments in the event of sickness or death of one spouse.
2. Give middle-aged and elderly home buyers a chance to make higher mortgage payments during the initial period of home ownership, with tapering monthly installments for advancing years.
3. Provide those covered by pension plans with an option to use part of their pension credit as the down payment on retirement housing.

Held believes that, on the basis of present life expectancies, the final age limit on which mortgages might be made could reasonably be increased to 75 or even 80 years of age for home buyers aged 65 and over.

A village within a city—The Presbyterian Home in Evanston, Ill., recently announced it would turn its 43-acre site into a community of cottages, duplexes, apartments, and a convalescent home for the elderly. Completion will raise the home's population to 600 from its present 165. Present facilities include a hospital.

An Asset—Not a Liability

Healthier Senior Citizens Can Solve Their Own Problems

"If we can—through research—find ways for older people to remain healthier for a longer period of time . . . then we will see our aging population not as a problem or series of problems, but as a magnificent asset."

This was the optimistic picture painted by Rep. John E. Fogarty (D., R. I.) at the first national conference of the Joint Council for the Health Care of the Aged, held June 12-14 in Washington, D. C.

He based his bright hope on results expected from continued and increased efforts in research sponsored by both the National Institutes of Health and private institutions. He advocated extending the search beyond the borders of this country. Representative Fogarty said, "Some nations may already be ahead of us in research on aging. In Sweden, for example, they were carrying out farsighted programs to aid their older persons some years before aging attracted interest in this country. It would be to our benefit to learn more of what other nations are doing."

More than 450 physicians, dentists, hospital and nursing-home personnel, and others interested in the aged attended the conference. The joint council—sponsor of the affair—includes in its membership the American Dental Association, the American Hospital Association, the American Medical Association, and the American Nursing Home Association.

Whatever the values of future clinical research, warned Dr. Ewald W. Busse, director of the Center for the Study of Aging at Duke University, it would be a mistake to wait for all the results. He said, "We are in an interim period; and while we are waiting for the results to appear we must fill in the gaps and move in some positive direction."

Governor Robert Meyner (upper right) of New Jersey was among more than 35 persons invited to address the first national conference of the Joint Council on the Health Care of the Aged.

Get a Second Career

One way to beat compulsory retirement at 65 is to embark on a second career.

This solution is offered to those who dread the inactivity of retirement by a 75-year-old California woman who is a walking advertisement for her own formula.

In 1944 Ethel Percy Andrus, Ph.D., voluntarily retired as a high school principal in Los Angeles, and since then she has founded two national organizations, become editor of two magazines, and traveled extensively. Her second career is in the field of counseling the aged, and the keynote of her advice is action. In a recent *New York Times* interview Dr. Andrus urged her retired peers to do things, be of service to others, and see the world.

She is president of both the National Retired Teachers' Association and an affiliate, the American Association of Retired Persons, and she founded both of them. Dr. Leonard Larson, chairman of the A. M. A. Board of Trustees, in a recent letter to Rep. Wilbur D. Mills, chairman of the House Ways and Means Committee, praised the hospital and surgical insurance coverage provided by the AARP for its more than 300,000 members.

The group has also built a home for retired teachers in California, and it arranges leisurely European tours for elderly persons with an urge to see the world.

The plan of immediate action advocated by Dr. Busse is a series of small conferences bringing together investigators, clinicians, and "action leaders." Such teams, he believes, would have the responsibility of working out plans of action and explanations and would make recommendations to the joint council, the government, and the public.

Other speakers at the Washington session outlined problems, suggested solutions, and told of their failures and their successes in dealing with all facets of the care of the aged. These are some selected comments:

Health Insurance—"Prophecy is always hazardous, but it is possible on the basis of past performance and a knowledge of current developments to project an estimate of future expansion of voluntary health insurance among the aged, assuming no interference or preemption by government. If reasonable allowance is made for factors that are improving the growth rate, a good case can be made for predicting that 65% of the aged who need and want voluntary health insurance will be insured by 1960, 80% by 1965, and over 90% by 1970."

E. J. Faulkner, Chairman
Health Insurance Council

Dental Care—"Finding dental conditions which need attention, and providing immediate treatment, will help the homebound or chronically ill patient psychologically and medically. When oral conditions are corrected the patient will have a better opportunity to handle food, improved esthetic appearance—leaving remaining energies of the patient to conquer or partly override his chronic medical disabilities."

Dr. Leonard Reichman
Adjunct, Dental Division
Albert Einstein Medical Center

Attitudes—"Unfortunately, the concept of aging as expressed in earlier days was not a very joyful one. These pronouncements have done much to create the unrealistic gloomy backdrop upon which the problems of aging are grafted today. Is it not now understandable why everyone, including the physician, has had his thinking tinted by this somber mood?"

Dr. Frederick C. Swartz, Chairman
A. M. A. Committee on Aging

Rehabilitation—"When the value and contribution of restorative services in hospitals is being evaluated, it is important that both sides of the coin should be examined. That is, not only the operating cost but also the financial gains achieved by shorter hospitalization, cheaper nursing care, economical use of available beds, and decreased welfare expenditures. There are also many intangibles such as the elimination of depressive states, preservation of family structure, and improvement of the professional atmosphere in hospitals."

Dr. Michael M. Dasco
Goldwater Memorial Hospital
New York City

Home Care—"Blue Cross participation would help to hasten the development of organized home-care programs. Heretofore, these programs have been financed mainly by grants and private or tax funds on a time-limited basis. In most Associated Hospital Service (N. Y.) member hospitals more than 50% of the patients are subscribers. In some hospitals 80% are subscribers. Therefore, payment by AHS for home care used by subscribers would help to stabilize the financing of organized home care."

Maria Phaneuf, R.N.
Associated Hospital Service

Use of Facilities—"Some relatives feel that releasing the patient to a nursing home is evidence that the hospital no longer believes the patient is treatable. Others feel the care in the hospital is more adequate. Some feel that they will have to bear all the cost of care in a nursing home. These misconceptions emphasize the need for the preparation of the relative for the patient's release. The patients too must be prepared for their leaving, since many have become 'institutionalized' and fear to depart."

Drs. Cecil Wittson and Jackson Smith
University of Nebraska College of
Medicine

Poor Housing and the Aged

Eight million Americans 65 or more years of age are forced by financial circumstances to live in dilapidated quarters of our communities, under conditions which promote mental and physical illness and crippling disabilities.

So says Wilma Donahue, Ph.D., who heads the University of Michigan's Division on Gerontology. She testified recently before a U. S. Senate subcommittee on problems of the aged.

Dr. Donahue said this is a problem that must be faced by the communities themselves, since only 10% of retiring workers can be expected to leave their home towns. She advocated a larger supply of good housing and well-planned developments to serve older people, who usually move in with their children "only when forced to do so because of long-term disabling illness, absence of income, or devastating loneliness brought on by the loss of spouses or other social contacts."

Dr. Donahue did see one bright spot in the aging picture. She said, "There is evidence that older people are trying to maintain their independence as long as possible. The average age at which they enter institutions offering sheltered care is rising."

Lobby for the Aged?

Do the nation's elderly form a persuasive political entity?

Not yet, according to testimony heard recently by a U. S. Senate subcommittee on problems of the aged, but the potential is there. Louis Kuplan, president of the American Gerontological Society, testified that so far the aged are not homogeneous either socially or politically. The witness said he believes, however, that society might turn them into a voting bloc if it continues to treat them as it now does (see Medicine at Work, The Journal, July 27, 1957).

"We could have a gerontocracy instead of a democracy," Kuplan said.

How Teamwork Is Solving . . .

By default, for more than a quarter of a century El Paso General Hospital had been dragging and sagging. Average patient stay was far too long. Extra tax funds, borrowed repeatedly in desperation, barely plugged deficit holes. All three Texas medical schools refused to authorize internship training there. And in the face of a tripling population not a single bed had been added since 1932.

But last month, as a new board of managers took control, plans were blossoming for a new hospital starting next year. It will cost between 4 and 5 million dollars and will be double the size of the present facility by 1962.

There is no magic in El Paso General's turnabout. Rather, the story is one of voter understanding of a critical health problem which was brought to the attention of the community by energetic physicians.

Actually, the El Paso County medical society had not one but two tasks to perform, if it were to give its community the leadership needed to correct a major health deficiency. For many years the hospital had been in trouble. Ostensibly a county facility for indigent patients, it had had to turn to the city of El Paso in recent years for money enough to manage even marginal operation. Even then, the funds appropriated lagged far behind the rising costs and increased patient loads. Everyone agreed the hospital was in bad shape. The question was—what to do about it?

The first action of the El Paso society was to form a fact-finding commission, with community representation, to find out what might be done. After months of study the commission recommended that a hospital district take over operation, maintenance, and expansion.

Since creation of such a district required a

The Hospital of Tomorrow Is Being Planned for Today

No new health facility should be constructed in an area until it has been preceded by a comprehensive survey of the health resources and needs of the area or under the supervision of a competent authority.

Community giving should provide a significant percentage of a patient-care facility's capital needs, to insure a high quality and an appropriate quantity of services.

The nursing home as it relates to the care of our older population overlooks the need of younger people for nursing services.

Such thoughts and recommendations emerged from the workshop sessions of four recent regional conferences devoted to the "development of principles for planning the future hospital system." Sponsored jointly by the Public Health Service and the American Hospital Association the series, ending May 15, brought together physicians and hospital administrators, nurses and educators, architects and insurance officials. All were undismayed by the warning of Dr. Leroy Burney, PHS Surgeon General, that "finding the answers—or, indeed, isolating the relevant questions—will not be easy."

Dr. Burney offered three reasons why the groups should be meeting then to seek planning principles for the hospitals of the future:

—In the hospital insurance business demands for broader coverage without increased premiums have created a dilemma.

—Hospitals can rightly point to forces beyond their control which affect their economy.

—No single element of the nation's hospital system, or those who contribute to its development, can make effective plans on its own; not only are we dependent on one another but we also run a risk of doing real damage to each other and the public by developing isolated plans.

Drs. Robert L. Novy of Detroit and W. C. Stover of Boonville, Ind., both members of the A. M. A. Committee on Medical Facilities, took part in the workshop sessions, which produced statements on such matters as:

PERSONNEL: In planning individual facilities consideration should be given to developing organizational patterns of patient care which will insure the most efficient use of personnel (see Medicine at Work, The Journal, April 26, 1958).

FACILITIES: The general hospital of the future probably will be the focal point of community health emphasis.

CHARITY: Charges to patients, prepayment plans, or health insurance companies should be set at a rate that excludes the cost of care of indigent patients, which is the responsibility of government and private charity.

DUPLICATION: Community planning might avoid unnecessary duplication of expensive or little-used facilities, such as cobalt bombs, radioisotopes, and artificial kidneys.

If the conferees had trouble finding sound infor-

. . . a Texas Health Problem

successful referendum, the medical society's next action was to help form a citizens' committee for the hospital district. In doing so it enlisted the aid of as many local organizations as possible, in an effort to insure widespread support.

The citizens' committee conducted an educational campaign based on two themes—that the hospital district was the most economical way to raise the necessary operating funds, and that all district residents, as well as indigent persons, would automatically be taken to El Paso General if they required emergency treatment.

Every avenue of communication was used to promote the district idea. Background material was prepared for speeches and news stories, telephone committees reached 19,000 property owners, social and civic clubs were taken on tours of the hospital, and speakers were provided for organizational programs.

A major publicity effort was handled by the society's women's auxiliary, who addressed two sets of post card advertisements to a total of 48,000 people.

The effort was a success. Voters last November approved the creation of a taxing district for El Paso General and supplemented it with a thundering eight-to-one approval last April of a $3,700,000 bond issue for new construction. Hospital officials are preparing this month to apply for an estimated $1,500,000 more in Hill-Burton matching funds.

Apparently El Paso County's residents saw the logic of the citizens' committee's often repeated statement that "a well equipped, staffed, and ever ready general hospital is a public insurance policy on behalf of every citizen."

mation on which to base their projections for the future, Dr. Jack C. Haldeman, for one, wasn't surprised. The assistant surgeon general said, "There is probably no other business which spends such a small amount for research. Hospitals spend more than 6 billion dollars a year to bring services to the people and employ more persons than either the auto or steel industries, yet it is estimated they spend less than 5 million dollars annually for hospital research."

What is Dr. Haldeman's estimate of a "reasonable and feasible" amount? Thirty to forty million dollars a year.

Nationwide Hospital Chain?

Inspired by a belief that the independent proprietary hospital may be as old-fashioned as the corner grocery, efforts are under way to establish a nationwide chain of "hospitals for profit." Whether or how this would contribute to hospital planning generally is a question with heavy overtones of economics. According to several published reports the hospital chain will stretch from coast to coast, with sites already being either improved or explored in New York, Illinois, California, and Arizona. All links would lead to Lake Murray Hospitals, Inc., whose president, David Seymour, is quoted as saying, "Accountants tell us that hospitals can be quite profitable in growth areas which now lack facilities and beds."

The Fight to Save VA Intermediary Care

The last shot fired in World War II was also the starting gun in the nation's race to keep its federal medical care programs abreast of a sudden heavy increase in the veteran population. Realizing that former methods of providing this care would be inadequate for the task the Veterans Administration enlisted the aid of the medical profession in setting up a program for outpatient treatment through private physicians. The plan came to be known as "Hometown Care."

On May 1 Hometown Care was the only item on the agenda when representatives of eight state medical associations met in Chicago with Dr. Turner Camp, VA Director of Clinics, and members of the A. M. A. Committee on Federal Medical Services, to discuss the way things were going.

All eight are holders of "Intermediary Contracts" with the VA for outpatient care of veterans with service-connected disabilities. (The Hawaii Medical Association also holds an intermediary contract but could not be represented at the conference.)

The intermediary contract is considered by the Committee to be the most effective of the three plans used by the VA to provide such care. Under this arrangement all contacts between the VA and the physicians are handled by a third party, usually the local Blue Shield plan. The third party negotiates fee schedules, receives and audits all physicians' claims, forwards them to the VA, transmits federal payments to the physicians, and acts as a review agency for both parties.

The nine state associations affected recently received notice that the VA planned to reduce the responsibilities of the intermediaries for fiscal 1960.

After the May meeting Dr. Russell B. Roth, chairman of the Committee, stated in a letter to Mr. Sumner G. Whittier, Administrator of Veterans' Affairs, "Intermediary Contracts, while perhaps not absolutely necessary, are still the best vehicle for bringing together the veteran with service-connected disabilities and the physician in private practice." He also noted that "there is no evidence to show that the VA can handle the functions now performed by the intermediary agencies . . . more economically."

For, lest anyone suspect the profession of a weighty financial interest in these matters, the approximately 38,000 physicians taking part in these VA programs receive an average of $13 per month.

Dr. Russell B. Roth of Erie, Pa., is chairman of the Committee on Federal Medical Services of the A. M. A. Council on Medical Service. Other members are Drs. Vincent W. Archer of Charlottesville, Va., Henry S. Blake of Topeka, Kan., Donald C. Conzett of Dubuque, Iowa, Robert S. Green of Cincinnati, Oscar B. Hunter of Washington, D. C., and J. Lafe Ludwig of Los Angeles. Staff Secretary is Mr. George W. Cooley of Chicago.

¿Habla Español, Doctor?

The call was from the captain of a Finnish freighter berthed at a Milwaukee pier. One of his crew was seriously ill, so he sought medical aid through the Milwaukee Physicians' Service. The request: Find a physician who speaks Finnish.

It wasn't the first such call that had posed a language problem for the medical society of Milwaukee County. Another ship of foreign registry had sought a doctor who spoke Croatian, and an emergency on dry land had pointed up the need to locate a physician with a knowledge of Hungarian.

As a result, the Milwaukee society polled its members and established a list of those with a usable knowledge of a foreign language. "We expect this list to become increasingly important now that the St. Lawrence Seaway is open," a spokesman said.

The benefits to be derived from such a listing are not restricted to port cities, however. The *Bulletin* of the Medical Society of the County of Monroe (Rochester) in New York reports that 65% of its members replied to a similar survey. The poll showed that 102 speak German, 71 speak French, and 58 Italian. Respondents also listed such other languages as Spanish, Polish, Yiddish, Greek, Danish, Lithuanian, and Chinese.

One unexpected dividend of the Rochester survey was the listing of a physician familiar with the sign language of the deaf.

Teeth, Lip Service, and A Schoolside Manner

Q. What is man's most common disease?

A. Tooth decay, which attacks 95% of our population.

Q. How serious are oral disorders?

A. They contribute to many physical, mental, and emotional health problems. Today, 30% of children in any given age group require orthodontic treatment, and it is probable that the present crop of youngsters will lose fully half their teeth by the age of 40.

Those facts, still not fully understood by a substantial segment of the medical profession, are brought out by Harold R. Harlan, D.D.S., of Newark, N. J., to point up the need for improved health programs in schools. Dr. Harlan's point is elaborated by a Doctor of Education, a Doctor of Medicine, and a registered nurse.

"There are barren areas in health instruction, areas which give lip service to it while denying the same in quantity and quality," says Robert E. Schneider, Ed.D., of Waterbury, Conn. "There is need for changed thinking on the part of some who, while condoning the incursion of every imaginable subject, deny a place in the same curriculum for instruction in an area of learning which is as essential to successful living as is instruction in the language which makes learning and communication possible."

A Philadelphia physician, Edward G. Sharp, suggests: "An objective for the school physician is a 'schoolside manner.' This concept assumes the school physician is professionally trained and active in medical and community affairs."

And a registered nurse, Dorothy C. Tipple of Albany, N. Y., noting the changing health needs of children, had this to say. "With the present focus on prevention of juvenile delinquency, we see the school's responsibility to cooperate with parents and with youth agencies in the development of an environment more conducive to social and emotional adjustment."

Those statements represent principles enunciated at the first annual preconvention session on school health, sponsored June 7 in Atlantic City by the 7,000-member American School Health Association in cooperation with the A. M. A.'s Department of Health Education. The 130 physicians, nurses, dentists, and health educators who attended the meeting also heard presentations by Dr. Gunnar Gundersen, immediate past-president of the A. M. A., and Ruth H. Weaver, M.D., immediate past-president of ASHA. By unanimous acclaim the audience recommended that a similar session be held in Miami Beach, prior to the A. M. A.'s next Annual Meeting.

Belief in Lifelong Study Cements the Medical World

Despite differences in language, technique, and tradition the world's physicians find a common ground in the conviction that medical practice carries with it the requirement of lifelong study. This will be evidenced in Chicago beginning late this month when the first of an estimated 1,500 doctors from more than 50 countries is expected to register for the second World Conference on Medical Education. The first was held in London in 1953.

Sponsored by the World Medical Association in cooperation with the World Health Organization, the Council for International Organizations of Medical Sciences, and the International Association of Universities, the conference to be held Aug. 31 through Sept. 4 will explore all phases of training for the profession of medicine.

The chief aim of the conference, according to Dr. Louis Bauer, secretary-general of the WMA, is to "accelerate the raising of standards of medical education and medical care by providing a world forum for the exchange of opinions on the methods and problems in postgraduate medical training of the physician." To accomplish this aim two of the four conference sections will be devoted to the study of advanced training for physicians, either for specialization or for continuing education. The remaining two sections will deal with basic clinical training and the development of teachers and investigators.

More than 120 speakers from many parts of the world have been invited to address either the plenary sessions or one of the section groups. Language differences will be accommodated by a simultaneous translation of all proceedings into English, French, and Spanish.

Such an international conference has been termed "invaluable" by Dr. Victor Johnson, deputy president of the conference and director of the Mayo Foundation for Medical Education and Research. He said, "It will be a medium for the exchange of ideas and discoveries, a stimulus to greater efforts directed to a better understanding of man and nature, and a means of fostering good will and friendship between the peoples of the world."

That this is more than just a pious hope is indicated by the fact that the Soviet Union, although not a member of WMA, is expected to send a delegation to the conference and will have two speakers on the program. Poland, another nonmember, will also be represented.

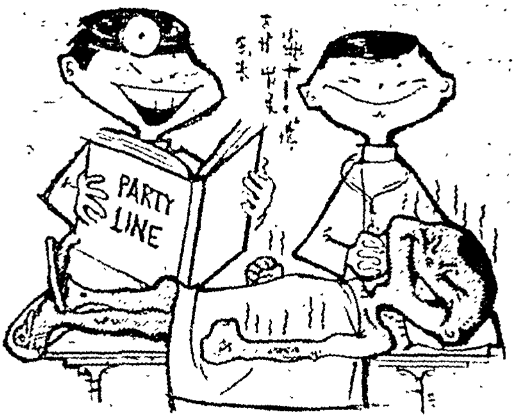
Party Line to the Rescue In Red China Medical Tale

If your medical miracles haven't been up to par lately, maybe you are politically disoriented. . . .

That point is made in a recent *Chinese Medical Journal* editorial which tries patiently to explain how extraordinary medical results can be achieved "when politics take the lead over scientific theory."

It seems that politically shortsighted Chinese physicians "unanimously predicted an unfavorable prognosis" when a steelworker suffering burns over "89.3% of the body surface" was brought to a Shanghai hospital. But, the editorial continues, no sooner had the assembled physicians shaken their heads in fatalistic despair than "a message was received from the Party Committee at the Shanghai Third Steel Mill pleading—for the sake of steel production and in order not to disappoint the workers of the whole mill—to save the wounded worker at all cost." This got the ball rolling, it appears, and the medical school's Party Committee quickly "analyzed the ideologic state of the doctors, and correctly pointed out that what could not be done in capitalist countries we could do."

A "case history" accompanying the straight-faced editorial is sparse in clinical detail but rife with melodrama and ideological therapeutics. Once their "initial error" had been made plain to them, the physicians were reported to have learned rapidly. "It's true that diseases can be treated by Marxism-Leninism," they allegedly chorused. "We shall make it our duty to cure all patients henceforth with burns within 90%."



By this time the general enthusiasm seems to have infected even the patient, who is quoted by the so-called medical journal as saying, "Cure me; I'm needed in production. I can leave my wife and child, but not my furnaces." Turning to his wife, who had brought his pay, he demanded to know, "Have you paid my Party dues?"

THE DIABETIC AND HIS EMPLOYMENT

GUEST EDITORIAL

Jean S. Felton, M.D.

MECHANIZATION and automation in today's industries have made possible the greatest potential utilization in history of workers with some degree of disablement. This change in production methodology has not necessarily resulted in the employment of all physically marginal persons, but has altered the physiological demands of jobs so that those with some capacity could work.

Outstanding in his effective contribution to the fabrication of the world's goods has been the diabetic, whose work situation has been aided even more by the introduction and use of orally given hypoglycemic agents. Recognizing this addition, the Committee on Employment of the American Diabetes Association has recently reissued its Statement on Employment of Diabetics,[1] originally offered in 1952, and revised at intervals. Criteria are offered as guides in their employment in industry or business.

To the prospective employer and the interested physician examining applicants for work, diabetics fall into several groups. The mild diabetic, whose condition is diet-controlled, in no need of insulin, and the selected diabetic, whose condition is controlled by a sulfonylurea compound and diet, present no problem in employment. Of a third group, severe diabetics, requiring both insulin and diet regulation, the well-controlled, well-regulated, cooperative patient should be accepted for work. It is the comparably categorized diabetic, however, who becomes the poor employment risk because of lack of control and regulation. Not only is this unstable clinical state a difficult one to care for in competitive industry and commerce but it is fraught with the constant threats of complications and absenteeism. Unnecessary prejudice against all diabetics can result from the injudicious employment of the patient who is not motivated to good self-care under medical counsel.

In a survey conducted by the Committee on Employment of the A. D. A.,[2] it was learned from 127 companies with a total of 1,900,000 workers that 69% employed known diabetics. Regarding their "experience as to reliability and absenteeism," 51% felt it to be satisfactory and 47% claimed it to be "same as average worker." There were differentials in hiring among the varieties of industries questioned, with five out of five railroads, as an example, indicating that they do not employ persons with diabetes. The percentage of diabetics in the companies reporting was 0.58%, a little under the average for diabetics in the general population, estimated at 0.75%.

The Committee on Employment has offered these suggested standards for employment: 1. The diabetic job applicant should bring a statement from his physician stating that he is controlled and is examined periodically. 2. Although the diabetic can perform any work for which he has physical, mental, and educational capacities, those who take large doses of insulin should not be assigned work wherein hypoglycemic attacks might lead to injury to themselves or others. In those under control solely by an oral preparation, symptomatic hypoglycemia is not a factor. 3. The diabetic should work the same hours in a steady shift, but if he must rotate he should avoid the midnight to 8 a. m. tour. 4. It is wise to have key people in labor and management informed of the nature of diabetes and the possibility of coma or insulin reaction, and the decision regarding this should be left with the plant physician. 5. The diabetic should carry a card with him which identifies his condition. 6. When the usual laboratory facilities on the outside are available only during working hours, time for the company can be saved and the employee helped by having the industrial medical department perform frequent blood sugar and urine examinations. 7. An annual physical examination should be made on each diabetic. 8. The plant physician is within his rights if he requests another work assignment for the diabetic, when new complications create additional risks. 9. The insulin-requiring diabetic should be considered controlled if the fasting blood sugar level is not below normal and not above 150 mg. per 100 cc. of blood, the three-hour postprandial level is not higher than 250 mg. per 100 cc., all by the Folin-Wu method, and he is under regular medical supervision.

---

[1] Employment of Diabetics, Statement of the Committee on Employment, American Diabetes Association, from the Report of the Committee, as accepted by the Council of the Association, June 7, 1952, New York, American-Diabetes Association, June, 1958.

[2] Analysis of Survey Concerning Employment of Diabetics in Some Major Industries, Organization Section, Diabetes 6:550 (Nov.-Dec.) 1957.

These standards, or criteria, are practical ones, and the time concession is the only one asked for the well-controlled diabetic worker. Persons with this condition have worked well in nearly all types of employment, and their production, attendance, and low injury records bespeak the wisdom of the utilization of this manpower. The blocks to their acceptance, as with other somewhat physically limiting conditions, are to be found in false, prejudicial, frequently rationalized thinking, based on unsound emotional responses of the prospective employer.

It is through the enlightened help of the physician and the employer that more diabetics will be given opportunities to demonstrate their skill on the job. Needing little medical surveillance while at work, they can make a considerable contribution to the production of the world's goods.

THE NEW CUMULATED INDEX MEDICUS

An agreement has been made with the National Library of Medicine in Washington, D. C., whereby the American Medical Association will publish annually in cumulated form the bibliographic references which appeared in the preceding year in the Index Medicus, a name which the present Current List of Medical Literature will assume in January, 1960.

The offer of the National Library of Medicine to provide the American Medical Association with the cumulated copy in film form was accepted by the Board of Trustees at the Atlantic City meeting in June, at which time the trustees decided also to discontinue publication of the Quarterly Cumulative Index Medicus with volume 60 (July-December, 1956), which volume recently was mailed to its subscribers. The format of the new Cumulated Index Medicus will be closely like that of the Quarterly Cumulative Index Medicus, and it will eventually provide a truly world-wide coverage of medical literature, probably as many as 180,000 titles.

The American Medical Association will publish independently of the government and at its own cost the new Cumulated Index Medicus, and the Superintendent of Documents at the Government Printing Office in Washington, D. C., will continue to sell the monthly index published for many years by the National Library of Medicine. Those hospitals, libraries, and individuals who have been subscribers to Q. C. I. M. and who desire to fill the gap—1957-1958-1959—will be able to obtain copies of the Current List of Medical Literature for those years, through the National Library of Medicine.

The ever-increasing amount of medical literature and the difficulty since World War II of finding personnel fitted for this specialized work caused the Q. C. I. M. to fall behind its former schedule almost two and one-half years. The same conditions caused the National Library of Medicine to survey the field for additional help and finally to adopt modern machine methods which will do rapidly what heretofore has been done by hand.

While this change-over has affected some 27 faithful and devoted employees who worked on the Q. C. I. M., most of them have either been agreeably assigned to other positions in A. M. A. headquarters or have been able to obtain positions elsewhere. The devotion of these employees to Q. C. I. M., an index which was long a favorite of physicians and other medical investigators throughout the world, is gratefully acknowledged.

Dr. John Shaw Billings and Dr. Robert Fletcher started the first Index Medicus in 1879 at the Army Medical Library. The American Medical Association began publishing the Quarterly Cumulative Index to Current Medical Literature in 1916. The two indexes were combined in 1926 and published by the American Medical Association as the Quarterly Cumulative Index Medicus with the financial assistance of the Carnegie Institution in Washington, which contributed toward the expense $10,000 per year for five years. The Quarterly Cumulative Index Medicus has never been a self-sustaining venture, and since the termination of the agreement with the Carnegie Institution it has cost the Association many thousands of dollars a year. Nevertheless, the trustees looked upon this project as one of the finest of many efforts that the Association has made to aid world progress in medicine. Now that the Q. C. I. M. has been discontinued, another—the annual Cumulated Index Medicus—will take its place.

A. M. A. DISAVOWS VITAMIN ADVERTISEMENT

An advertisement which cleverly implies endorsement by the American Medical Association of a brand of vitamin capsules has been strongly disavowed by the A. M. A. The book entitled "Book of Health," edited by an A. M. A. employee, was offered free by Vitasafe Corporation, New York City, along with a supply of their capsules. The words, "The Official American Medical Association Book of Health" show up prominently in the advertisements appearing in newspapers and magazines along with a photograph of a bottle of the capsules. This was done without A. M. A. knowledge or approval.

The A. M. A.'s official statement regarding vitamins (THE JOURNAL, January 3, 1959, page 109) states that, if a healthy person's diet contains the key food groups in sufficient amounts, nutritional supplementation is unnecessary. There has been no change in this policy.

COUNCIL ON NATIONAL DEFENSE

The following paper is being presented through the Council and its Committee on Disaster Medical Care as a matter of interest to physicians and hospitals interested and active in medical civil defense preparedness.

FRANK W. BARTON, *Secretary.*

FUNCTIONS OF A HOSPITAL IN A MAJOR DISASTER

Frank F. Schade, M.D., Los Angeles

It is the accepted obligation of our profession to give the very best possible medical care to our fellow citizens at all times and under any circumstances. This, of course, includes disaster medical care.

Disasters can strike any time, any place, and they need not be caused by war to be of major proportions. What is a major disaster? It must be relative, depending on the locality affected. As an example, a fire or earthquake that would destroy a dozen blocks in a smaller city could be considered major, but it probably would not be so thought of in one of our larger cities.

To oversimplify the answer, the functions of a hospital are to furnish the best possible medical care to the victims of a disaster, under the existing conditions. There are three principal possibilities of hospital involvement and function.

Disaster in Hospital Itself

The first possibility is in the event the hospital itself is involved in a disaster; this could be limited to any one hospital, as in the event of a fire or explosion in the hospital. In this situation, as in all of the others, the basic premise is that carefully considered plans have been drawn up and then tested and retested until they are so modified that they are as nearly perfect as humanly possible. The very first consideration of any hospital should be for this contingency and is concerned with rapid evacuation of patients and personnel. This may sound simple, but actually it involves a myriad of details. For every method or action, there must be a substitute in the event something would prevent its accomplishment. If a certain door is planned for an exit, there must be an alternative choice in case the door be blocked by flames or a fallen beam or simply jammed. If there are elevators, what is to be done if power fails?

If there is not time to remove all patients, which will you evacuate and which will you—yes—abandon? This type of decision is most difficult to make under the best of planning conditions but is impossible to make under the stress of the emergency. A priority system is one of the essentials and should be based on the future value of that person to the community. It follows that the highest priority should be given to children without preexisting handicaps, to women in the childbearing age, and to other younger adults. The aged, those suffering from incurable conditions and advanced degenerative disease, should have the lowest priority. This is a repugnant thought but it is a decision that possibly could be forced on us. It exemplifies one of the basic tenets of all disaster work, no matter what the branch—do the best for the most.

Planning must include a place that can be used as a substitute for the hospital, to which the evacuated patients can be taken. It should not be too near the hospital, otherwise it could also be involved in the incident that caused the hospital to be abandoned. Transportation must be considered, and large flat bed trucks, such as moving vans, are ideal for the mass movement of patients.

If time and available personnel permit, small, essential supplies and equipment should be removed from the hospital, perhaps in pillow cases. Antibiotics, sedatives, antiseptics, analgesics, dressings, small instruments, syringes, and needles are but a partial list of things more urgently needed. A definite understanding, preferably in writing, to cover this emergency removal should be had with the hospital ownership and/or management. A rendezvous point for the staff, personnel, and employees of the hospital should be known to all concerned. This could well be the place of the substitute or auxiliary hospital.

Disaster in Hospital and Area

The second consideration is of the hospital that is located in a disaster area not limited to the hospital itself. It divides itself naturally into two possibilities —with and without warning of the disaster. Warning is possible, both in war and natural disasters. If there is no warning, then the previously discussed considerations would apply.

Chief, Medical and Health Section, Los Angeles County and Cities Civil Defense Planning Board.

If there is warning, complete, orderly, and less hurried evacuation and dispersal can be accomplished. Larger and more complete lists of the smaller items of supply and equipment can be removed, including canned and packaged food supplies and some cooking equipment. A new word and concept, "dispersal," enters here—this, in contradistinction to the previously considered evacuation. One of the objectives in dispersal is the actual discharge of the maximum number of convalescent patients, either to the family or to a welfare service. There are a number of reasons for this.

A much greater degree of cooperation also becomes necessary—cooperation, undoubtedly with other hospitals and certainly with other services of the disaster organization. Communications, transportation, supply, welfare, and traffic control are those services that would be involved in this phase.

During dispersal it is probable that the patients from several hospitals would be consolidated into one convoy to go to a common destination. Attendants must accompany these patients and certainly should include any house staff, nurses, and aides. It would also be most desirable for some of the attending staff to go along. These dispersees will be patients, some quite ill. The trip could take many hours, so some of these patients could require considerable attention en route.

Hospitals in Support Areas

All of the hospitals in the disaster areas must have plans for the reception and care of disaster victims. This phase can be discussed in the third and final category of hospitals that are located in the reception or support areas.

The cardinal functions of hospitals in the support areas are (1) the discharge of the maximum number of convalescent patients, (2) implementation of expansion plans, (3) reception of and care of dispersed patients and disaster casualties, and (4) assistance in setting up and operating emergency hospitals. In view of the first two functions, for the satisfaction of all concerned, reliable and accurate intelligence is a requisite. It is very easy to visualize the utter demoralization that would result in any support area if the word were passed to put these plans into operation and then to have them later rescinded.

Obviously the first step in making room for an anticipated or actual flood of patients is to discharge every possible patient currently in the hospital, to family, friends, or the welfare service. If there should be any urgency in this, as there could well be, it is essential that two provisions are agreed on in advance by the staff. The first is a current grading system of all hospital patients, designating those who can be immediately discharged, those for whom some degree of medical supervision is desirable, and those who should be evacuated or dispersed and remain in the system of medical care. The second is the delegation of the necessary authority, based on the grading system, to certain persons to go through the hospital and actually order the discharges of the patients, without the actual consent at the moment of the patients' attending physicians.

The next step is the implementation of the expansion plan. Every available square foot of space must be used. This does not mean simply converting private rooms to capacity of two or three patients. Auditorium, class rooms, solariums, halls, and any other available space must be used. If there is a nurses' residence and/or a separate building for a school of nursing, this would be very important for convalescent patients and possibly for the obstetrical department.

In the plan, careful attention should be given to admission of patients; this may require that the admitting department be relocated. In many hospitals this department could not possibly take care of mass admissions. Available entrances, streets, driveways, and parking lots are factors to be considered, as well as adequate space. Planning should also provide for a first-aid facility forward of the admitting area to screen out the lesser injured and thus reserve hospital space and care for only the most acute and serious cases.

Either adjacent to or very near the admitting area should be a large area for triage and resuscitation. This is one of the most important departments and should be supervised by one of the best and most experienced surgeons, who is mentally and emotionally well adjusted and stable. This requirement cannot be overemphasized, for he will have to make the decisions as to which patients will be cared for first, which ones can wait for hours, and even which ones must simply be kept as comfortable as possible until they die. The basic principle is to use all facilities most efficiently, and this means that the highest priority for surgical care will be for those patients requiring short—and the word short demands emphasis—lifesaving procedures. In a major situation an operating room cannot be retained for three or four hours for one patient when several others could be cared for in the same period of time.

The expansion plan includes the provision of additional surgical facilities. This may be accomplished in several ways; some large operating rooms can have two tables instead of one, additional operating rooms frequently can be created in the surgical suite, and consideration should be given to the use of delivery rooms for surgery. More efficiency of operation is frequently achieved if certain floors or areas of the hospital are designated for particular types of cases, as for burns, fractures, and postoperative care.

Kitchens can rarely be enlarged, but attention should be given to altered schedules and types of food. Most of the acutely ill patients will get liquids. The biggest problem will be that of feeding all of the personnel who will remain at the hospital for a number of days on around-the-clock schedules.

Laboratory work will be very limited in its scope. Large quantities of blood will be necessary, so blood procurement must be arranged for. This area must be readily available to donors and should be located so that this traffic does not interfere with patient and attendants traffic flow. In many hospitals this will require that it be set up away from the existing laboratory.

Finally, provision must be made for adequate morgue space, since this type of disaster results in an unusually high mortality rate.

Provision should also be made for an auxiliary to the hospital, with minimal equipment, to which convalescent patients can be transferred as soon as their condition warrants it. This is necessary to keep bed space available for the constant flow of acutely ill patients admitted, that could very well extend over a number of days.

Another function that poses a perplexing personnel problem is concerned with the 200-bed emergency hospitals. Our plan is to use these units as nuclei around which will be created hospitals of from 500-bed to 1,000-bed capacity. Many of the units have been prepositioned in localities considered to be safe distances from anticipated danger zones. These safe areas naturally are in the more sparsely populated counties. The problem is compounded by the expected tremendous increase in the population of these counties, of both well evacuees and those requiring medical care and treatment of wounds, plus the normally small number of medical and allied personnel and the few hospital beds available in these counties. The only possible answer is the reinforcement of the expanded existing hospitals by these enlarged emergency hospital units.

In a situation of dispersal, these units should be set up at their original capacity and be used to care for the hospital patients from the danger zones. This would permit the personnel to become familiar with the hospital under the most favorable conditions and at the same time would conserve the beds in the existing hospitals for the first influx of casualties. On notification of the occurrence of the disaster, expansion could be affected. If the disaster occurred without warning, the units would be set up at once at their expanded capacity.

The personnel shortage will eventually be greatly alleviated by the arrival of medical and allied personnel from the dispersed areas. A few will arrive with the convoys of the hospital patients. Others will come to the area by prearrangement or as members of the dispersed population. Suddenly, under the most unfavorable professional and emotional conditions, there will be thrown together doctors from different sections of the state who have widely differing backgrounds of culture, training, ability, and experience. Here is where cooperation, understanding, teamwork, and the suppression of professional pride and vanity will be important.

As the dispersed persons arrive, an additional function of the hospitals, and especially the improvised emergency type, will be to furnish care for these people. Hospitalization by necessity must be restricted to the care of only the patients with the most acute and urgent conditions. Many patients who normally would be treated in hospitals will be cared for in some other manner. This same type of minimal care will also apply to the resident population.

A few of the basic concepts relative to the functions of hospitals in major disasters have been superficially discussed. Briefly stated, the functions are (1) the protection and safeguarding of the present hospital patients, (2) the best possible care of the disaster victims, under the circumstances, following the dictum of doing what is best for the most, (3) minimal care for the resident population, and (4) minimal care for the dispersed.

GOVERNMENT SERVICES

AIR FORCE

Space Medicine Course.—The School of Aviation Medicine will offer a new advanced course in aerospace medicine to senior medical officers from the air forces of our allies at its new home at Brooks Air Force Base, Texas. The starting date for the first course is Sept. 8. Prerequisites for attendance in the 27-week course include prior satisfactory completion of the primary course in aviation medicine conducted by the school; a minimum of one year of practice in aviation medicine subsequent to completion of the primary course; and a reading, writing, and speaking knowledge of the English language. The purpose of the course is to prepare allied senior medical officers for professional responsibilities as aviation medicine consultants, investigators, teachers, and directors of programs in their respective air forces. The course will consist of 1,078 instruction hours, divided into three parts: part 1, academic aviation medicine; part 2, physiological training program; and part 3, practical aspects of aviation medicine. The latter will be conducted at air training command bases with instruction and supervision by practicing air force flight surgeons.

Personal.—Col. Lawrence J. Milch, chief of the department of pharmacology-biochemistry at the Air Force School of Aviation Medicine and recent winner of the Air Force's commendation medal for his work in heart diseases and motion sickness, will become deputy commander of the 6,102nd Air Base Wing at Yokota, Japan.

ARMY

Personal.—Brig. Gen. Thomas J. Hartford, Army Medical Corps, was appointed deputy surgeon general of the United States Army. His predecessor, Major Gen. James P. Cooney, has been named chief surgeon, U. S. Army, Europe.

PUBLIC HEALTH SERVICE

Dr. Freund Honored.—Dr. Jules Freund, internationally known immunologist, was selected as recipient of a special citation from the Allergy Foundation of America. Dr. Freund is in charge of basic studies on allergy and immunology at the National Institutes of Health, U. S. Public Health Service, Bethesda, Md. The allergy foundation is a nonprofit organization which operates a program of public and professional education and training in the field of allergic diseases with headquarters at 801 Second Ave., New York 17. One of Dr. Freund's most important contributions was his demonstration of the increased effectiveness of vaccines in which the protective materials are incorporated in water-in-oil emulsions. The latter, known as Freund's adjuvant, has provided tools used routinely in basic laboratory research by immunologists here and abroad.

New Indian Service Hospital.—The Public Health Service awarded a $1,391,700 contract for construction of a 50-bed hospital and staff living quarters at Sells, Ariz., to serve the Papago Indians. Since 1947, when the Oasis Hospital at Sells was destroyed by fire, Papago Indians have been served by the Public Health Service Indian Hospital at Tucson, 150 miles away. The new hospital will include outpatient and field health facilities for additional services to about 8,000 beneficiaries living in 73 isolated villages of the 4,000-square mile Papago Reservation. The new, centrally-located hospital should be completed by 1961.

NATIONAL SCIENCE FOUNDATION

Postdoctoral Awards.—Applications will be accepted through Sept. 1 by the National Science Foundation for a second group of postdoctoral fellowships. Fellowships will be awarded in medical and other science fields. Names of successful fellowship candidates will be announced on Oct. 15. To be eligible for postdoctoral fellowships, candidates must be citizens of the United States with special aptitude for advanced training and must hold the doctoral degree or have the equivalent in training or experience. Fellows will be selected on the basis of ability as evidenced by letters of recommendation and other evidence of scientific attainment. Candidates' qualifications will be evaluated by carefully chosen panels of scientists operating under the aegis of the National Academy of Sciences–National Research Council. Final selection on fellows will be made by the National Science Foundation.

A stipend of $4,500 per year will be awarded to successful applicants. Dependency allowances will be made to married fellows. Fellows may engage in study and/or research at any accredited nonprofit institution of higher education in the United States or any nonprofit foreign institution of higher education. A limited allowance to aid in defraying a fellow's cost of travel will also be available. Application materials may be obtained by writing to the Fellowship Office, National Academy of Sciences–National Research Council, 2101 Constitution Avenue, N. W., Washington 25, D. C.

Research Laboratories.—The National Science Foundation has a new program for renovation and/or construction of graduate level (doctoral) research laboratories at institutions of higher education. Generally speaking, equipment to be supported will be limited to standard fixed equipment (e. g., laboratory benches, built-in refrigerators, etc.), whether the grant is for construction of a new laboratory or the renovation of an existing one. Proposals pertaining to laboratories for research use in any area of the basic sciences will be considered, but the foundation will not consider requests for support of facilities to be used primarily for instructional purposes. Grants made under this program will require matching by the institution, from nonfederal sources, to the extent of at least 50% of the direct costs to be incurred. Proposals should be submitted to the division of biological and medical sciences, National Science Foundation, Washington 25, D. C., by Dec. 1, 1959. In most cases it will be helpful to address an inquiry to the appropriate division of the foundation before preparing the proposal. It is anticipated that grants under this program will be made about June 1, 1960.

MEDICAL NEWS

COLORADO

Dr. Stonington Named Division Head.—Dr. Oliver G. Stonington, member of the volunteer faculty of the University of Colorado School of Medicine, Denver, since 1950, was named head of the division of urology in the department of surgery on a full-time basis. The appointment is effective Sept. 1. The position previously has been filled by volunteer faculty members on a part-time basis. Dr. Stonington is a diplomate of the American Board of Urology. He reportedly was instrumental together with Dr. Joseph H. Holmes, professor of medicine, in introducing the artificial kidney to the University Medical Center with which more than 250 patients have been treated.

GEORGIA

State Medical Election.—Officers for 1959-1960 of the Medical Association of Georgia are: president, Dr. Luther H. Wolff, Columbus; president-elect, Dr. Milford B. Hatcher, Macon; immediate past-president, Dr. Lee Howard Sr., Savannah; first vice-president, Dr. Corbett H. Thigpen, Augusta; second vice-president, Dr. Walter P. Rhyne, Albany; secretary, Dr. Christopher J. McLoughlin, Atlanta; speaker of the house, Dr. Thomas W. Goodwin, Augusta; vice-speaker of the house, Dr. Fred H. Simonton, Chickamauga.

HAWAII

Health Record of New State.—Statisticians of the Metropolitan Life Insurance Company reported that tuberculosis mortality in the civilian population of Hawaii was down to 3.1 per 100,000 in 1957, a decrease of more than 50% in two years and of about 95% since 1940. The 1957 death rate from influenza and pneumonia was only 25.6 per 100,000—half that of 1940. At the same time, the principal communicable diseases of childhood (measles, scarlet fever, whooping cough, and diphtheria) and typhoid fever have been practically eliminated as causes of death. The infant mortality rate in 1957 was 24 per 1,000 live births, compared with 44 in 1940. Currently three-fourths of the infant deaths occur in the first month; the comparable proportion in 1940 was three-fifths. Over the same period, maternal mortality has dropped from 2.4 per 1,000 live births to 0.4. Leading causes of death in Hawaii are heart disease (first) and cancer (second). Next in order were diseases of early infancy, cerebral hemorrhage, accidents, and influenza and pneumonia. Accidents are the leading cause of death in the 1-24 age group, nearly 45% of the fatal accidents in this age group resulting from motor vehicle mishaps. Longevity in Hawaii compares with that for continental United States. According to the life table for 1949-1951, the latest available for Hawaii, the average length of life for males was 67.76 years. The average for females was 71.29 years.

ILLINOIS

Society News.—Dr. Charles K. Petter, Waukegan, was reelected president of the Illinois Tuberculosis Association May 25 at the annual meeting in Chicago. Reelected treasurer of the organization was Dr. Jesse A. Stocker, Springfield. Meeting in conjunction with the association was the Illinois Trudeau Society, medical section of the state tuberculosis association. Officers elected were: president, Dr. Darrell H. Trumpe, Springfield; president-elect, Dr. Meyer R. Lichtenstein, Chicago; and secretary-treasurer, Dr. Raymond H. Runde, Peoria.——The officers for the Illinois Society of Pathologists for the coming year are Drs. Franklin J. Moore, Chicago, president, and James R. Thompson, Chicago, secretary-treasurer. The president of the society is the chairman of the pathology section of the Illinois State Medical Society and the secretary-treasurer is the secretary of the section.

KENTUCKY

Personal.—Dr. George W. Pedigo Jr., Louisville, recently became the first physician ever to be appointed to the Board of Directors of the Kentucky Chamber of Commerce. Dr. Pedigo is associate editor of the *Journal of the Kentucky State Medical Association*, vice-speaker of the house, and was recently elected president-elect of the Jefferson County Medical Society.——Dr. Daryl P. Harvey, Glasgow, was appointed by President Eisenhower as a member of the President's Citizens Advisory Committee on the Fitness of American Youth. This committee, which serves in an advisory capacity to the Council on Youth Fitness, considers and evaluates "existing and prospective governmental and private measures conducive to the achievement of a happier, healthier, and more completely fit American Youth." Membership is appointed from all sections of the nation. Last November Dr. Harvey was appointed a vice-chairman of the 1960 White House Conference on Children and Youth. Dr. Harvey is currently serving as president of the Kentucky Academy of General Practice.

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. Programs should be received at least three weeks before the date of meeting.

MASSACHUSETTS

Professors Retire.—Three professors retired from Harvard University on July 1, to become professors emeriti. They are Dr. Leland S. McKittrick, Brookline, clinical professor of surgery; Dr. Joe Vincent Meigs, Boston, clinical professor of gynecology; and Dr. Francis C. Newton, Boston, clinical professor of surgery. Dr. McKittrick has been associated with Harvard Medical School since 1932. Dr. Meigs has served as clinical professor of gynecology at Harvard since 1941 and has been associated with the Medical School since 1932. Dr. Newton was appointed in the department of surgery at Harvard as an associate in surgery in 1920.

Personal.—Dr. Walter F. Lever, of Chestnut Hill, who was associated with Harvard Medical School and Massachusetts General Hospital, will be the principal investigator of a new research department in dermatology at the Boston Dispensary. He will head the department of dermatology and syphilology at the dispensary. He also has been appointed clinical professor of dermatology at Tufts College Medical School.——Dr. Robert R. Mezer, of Boston, was appointed coordinator of the psychiatry training program at the Boston University Law-Medicine Research Institute. Dr. Mezer will also serve as assistant professor of legal psychiatry at the university's School of Law, and an assistant professor of psychiatry at the university's School of Medicine.——Dr. Robert H. Hamlin, Washington, D. C., assistant to Arthur Flemming, Secretary of the Department of Health, Education and Welfare, resigned to become professor of public health administration in the Faculty of Public Health at Harvard University, Boston.

Program in Pharmacology and Biostatistics.—A training program in clinical pharmacology and biostatistics related to diseases of the heart and blood vessels was established at the Lemuel Shattuck Hospital in Boston and the Harvard Medical School under a grant from the National Heart Institute of the National Institutes of Health. The program, which opened July 1, includes a combination of on-the-job training in the planning and execution of therapeutic trials and formal instruction in research techniques related to clinical pharmacology. Both the pre- and postdoctoral candidates will participate in the program. Course work will be available at the Lemuel Shattuck Hospital, the Harvard Medical School, and the Harvard School of Public Health. The candidates will be concerned with research projects in progress at the hospital. Dr. Frank A. Howard, research associate in pharmacology at Harvard, will direct the program in collaboration with Dr. Mindel C. Sheps, Boston, assistant professor of preventive medicine, and Dr. Thomas C. Chalmers Jr., Boston, clinical associate in medicine at Harvard. Candidates for the postdoctoral degrees are required to have an M.D. degree and should have completed the first portion of their training in internal medicine. Predoctoral candidates must have a B.A., M.S., B.S., or Ph.D. degree. Medical students will be required to have the recommendation of the dean of the faculty of medicine in their universities.

MICHIGAN

Dr. Hubbard Named Dean.—Dr. William N. Hubbard Jr., associate dean of the New York University College of Medicine, New York City, was appointed dean of the University of Michigan Medical School, Ann Arbor. The new dean succeeds Dr. Albert C. Furstenberg, who has headed the Medical School since 1935. Dr. Hubbard is the fifth person to carry the title of "dean" and the eighth to serve as administrative head of the Medical School since it was founded in 1850.

Dr. Foust Goes to Africa.—Dr. Joseph C. Foust, general practitioner from Ionia, left June 19 to spend a lifetime in the back country of Tanganyika, sponsored by the Foundation for All Africa, Inc., a nonsectarian group that devotes itself to furthering "person-to-person" contacts between Africans and Americans. Dr. Foust is taking along a truck, a house trailer, and his wife and six children. He is paying for the trip himself and "will devote his time to treating sick natives." "The decision to go to Africa was taken about a year ago," Dr. Foust said. "It is a matter of charity and justice." The family disembarked at Capetown in July to start a 1,500-mile drive to the village of Mboya on the south-central plains of Tanganyika.

MINNESOTA

Personal.—Dr. Walter A. Fansler, emeritus clinical professor of surgery, University of Minnesota Medical School, Minneapolis, was made an honorary member of the Royal Society of Medicine (Proctologic Section) at the joint meeting of the Royal Society of Medicine and the American Proctologic Society in London, England, July 1.——Dr. R. Drew Miller, consultant in medicine in the Mayo Clinic and assistant professor of medicine in the Mayo Foundation, Graduate School, University of Minnesota, was appointed assistant director of the Mayo Foundation by the board of regents of the University. Dr. Miller will continue to devote about half his time to the practice of internal medicine in the Mayo Clinic.——Dr. Reginald G. Bickford, head of the electroencephalographic laboratories of the Mayo Clinic, Rochester, was appointed a member of the Neurology Study Section of the National Institutes of Public Health, a unit of the U. S. Department of Health, Education and Welfare.

Personal.—Dr. Edward J. Van Liere, Morgantown, dean of the West Virginia University School of Medicine, has been elected an affiliate of the Royal Society of Medicine, London, England. The society was founded in 1805 and chartered in 1834.—— Dr. Robert P. Hagerman, recently retired from service with the Department of Justice, has been named by Dr. Richard J. Lilly, head of the West Virginia State Department of Mental Health, as superintendent of Weston State Hospital. He succeeds Dr. Lilly, who has served as superintendent during the past several months.

WYOMING

State Medical Election.—Elected officers of the Wyoming State Medical Society are: Drs. Benjamin Gitlitz, Thermopolis, president; Francis A. Barrett, Cheyenne, president-elect; S. J. Giovale, Cheyenne, vice-president; Frederick H. Haigler, Casper, secretary; Carleton D. Anton, Sheridan, treasurer; Albert T. Sudman, Green River, delegate to A. M. A.; and Bernard J. Sullivan, Laramie, alternate delegate to A. M. A.

GENERAL

Change of Address.—Mail intended for the Joint Commission on Mental Illness and Health, its officers, or its staff should be addressed as follows: Joint Commission on Mental Illness and Health, Massachusetts Mental Health Center, 74 Fenwood Road, Boston 15. Following conclusion of the study projects of the National Mental Health Survey on June 30, editorial offices will be maintained at the new address until publication work on the monograph series and final report is complete.

Books for Philippine Medical Library.—A request for medical books and journals from A. M. A. members has been received from Dr. Mercedes V. Planas, of Cebu City, Philippines, for the Cebu Medical Library. The organization, "Books for Asian Students," has agreed to handle the shipping. Publications should be shipped by motor freight, collect (not Railway Express or moving van). The shipment should be addressed to Cebu Medical Library, % Books for Asian Students, 21 Drumm St., San Francisco 11, Calif. Packing in ordinary cardboard cartons tied with rope is sufficient. Packages will be repacked for overseas shipment. Dr. Planas' address is P. O. Box 55, Cebu City, Philippines.

o,

as [illegible] **to Tour Russia.**—Six American physicians
[illegible]change mission to Russia on Sept. 5,
NEW [illegible]land. They are Drs. Cl[illegible]
New Yor[illegible] William B. C[illegible]
Break Grou
for the new
versity's medic
ceremonies for th

tutes and laboratories and then start a month-long itinerary which will include Leningrad, Sochi, Sukhumi, Kiev, and Odessa. Dr. Barborka, president, American Gastroenterology Association, is taking a previous tour to coordinate a program of medical researches in gastroenterology, which will take him to Sweden, France, Spain, the Netherlands, Germany, England, and Switzerland.

Otorhinolaryngological Congress in Paris.—The 57th French Congress of Otorhinolaryngology will take place Oct. 19-22 in the Grand Amphitheater of the Faculty of Medicine, rue de l'Ecole de Médecine, under the presidency of Dr. Andre Soulas, of Paris, and the honorary presidency of Prof. L. Binet, dean of the Faculty of Medicine of Paris. The program includes presentation of papers, and two reports will be discussed: (1) Surgery for Deafness—Its Present State, Its Future, and (2) The Laryngologist and Actual Data on Treatment of Acute Respiratory Insufficiencies. An exposition of surgical instruments, appliances, and pharmaceutical specialties will be held in the Hall of the Faculty. For information, write the General Secretary, Dr. Henry Guillon, 6, Avenue MacMahon, Paris 17, France.

Research Fellowships and Grants.—The Life Insurance Medical Research Fund is receiving applications for two types of awards to be available July 1, 1960, as follows: (1) Until Oct. 15, 1959, for postdoctoral research fellowships. Candidates may apply for support in any field of the medical sciences. Preference is given to those who wish to work on fundamental problems, especially those related to cardiovascular function or disease. Minimum stipend is $4,500 with allowances for dependents and necessary travel. (2) Until Nov. 1, 1959, for grants to institutions in aid of research on cardiovascular problems. Support is available for physiological, biochemical, and other basic work broadly related to cardiovascular problems as well as for clinical research in this field. Information and application forms may be obtained from the Scientific Director, Life Insurance Medical Research Fund, 345 E. 46th St., New York 17.

Occupational Health Congress in New York.—The 13th International Congress on Occupational Health will be held July 25-29, 1960, at the Hotel Waldorf-Astoria, New York City, organized under the auspices of the International Association on Occupational Health. The program will include physicians, nurses, industrial hygienists, and representatives from more than 40 countries. The following aspects on occupational health will be considered:
[illegible]ative methods, medical and surgical prac-
[illegible] and training, social and legal
[illegible] and psychology, environ-
environmental hygiene,
Persons who wish

tion offers grants for the support of the work of established researchers whose studies have a potential relationship to the problems of tuberculosis. The work must be in medicine, sociology, epidemiology, or the basic sciences, and the project must be conducted in an approved university, hospital, or other institution in the New York City area. Applications for fellowships must be made by Nov. 15, while those for grants-in-aid are due at least six months prior to the date when the contemplated project is scheduled to start. Forms may be obtained by writing the New York Tuberculosis and Health Association, 260 Park Ave. South, New York 10.

OREGON

Personal.—Dr. Robert G. Pittenger, Portland, is the new director of the Pacific Northwest Regional Blood Program, succeeding Dr. Bernard Pirofsky, who resigned his post recently to join the staff at the University of Oregon Medical School.——Dr. John A. Benson Jr., recently on the faculty in the department of medicine at Harvard Medical School, Boston, will become associate professor of medicine and head of the division of gastroenterology, University of Oregon Medical School, Portland. He will replace Dr. George B. Long, Portland physician, who has been acting head of the division on a part-time basis for several years. Dr. Long will remain on the faculty as an associate clinical professor.

TENNESSEE

Tennessee Valley Assembly.—On Sept. 28-29, the Tennessee Valley Medical Assembly will be held at the Read House, Chattanooga, sponsored by the Chattanooga and Hamilton County Medical Society. The program includes 17 scheduled papers, among which is "The Decisive Edge," by Dr. Louis M. Orr, Orlando, Fla., president, American Medical Association. Speaker at the banquet, Sept. 28, 7 p. m., will be Dr. Morris Fishbein, professor emeritus (Rush) University of Illinois, College of Medicine, Chicago, who will present "Medicine and the Changing Social Order." Registration fee ($15, payable to Tennessee Valley Medical Assembly) should be sent to Chattanooga Convention and Visitors Bureau, 819 Broad St., Chattanooga, Tenn. The program is approved for category I credit for members of the American Academy of General Practice.

University News.—At the invitation of the department of surgery, Meharry Medical College, Nashville, Dr. George T. Pack, of New York City, delivered the 12th annual Hale-McMillan Lecture April 30. The subject of this lecture was "Sarcomas of the Soft Somatic Tissues."——Feodor Lynen, Ph.D., a biochemist, from Munich, Germany, was the guest of Meharry Medical College March 26-28. His visit was made possible through the courtesy of the Squibb Centennial Lecture Committee.

TEXAS

Southwest Cancer Conference.—The 13th annual Southwest Regional Cancer Conference, sponsored by the Tarrant County Medical Society and the Tarrant County Unit, American Cancer Society, will be held Sunday, Sept. 20, at the Fort Worth Academy of Medicine. Speakers will include, Dr. Shields Warren, professor of pathology, Harvard University; Dr. Eugene P. Pendergrass, professor of radiology, University of Pennsylvania, and Dr. Warren H. Cole, professor of surgery, University of Illinois. For information, write the American Cancer Society, Tarrant County Unit, 264 West 11th St., Ft. Worth, Texas.

UTAH

New Address.—The Utah Tuberculosis and Health Association announced that its new address is Inland Building, 1941 S. 11th E., Salt Lake City 5, Utah (Telephone: INgersoll 6-9101).

VERMONT

University News.—A Ph.D. program in the University of Vermont College of Medicine department of pharmacology has been approved by the university trustees. It is anticipated the program will become effective during the fall of 1959. It becomes the second Ph.D. program at the university.

WEST VIRGINIA

Dr. Boysen Named Child Health Director.—Dr. Theophilus H. Boysen, III, chief of obstetrics and gynecology at Man Memorial Hospital in Man since 1956, accepted an appointment as full-time director of the division of maternal and child health of the State Department of Health. The office in the State Department of Health has remained vacant since Nov. 16, 1956, when the then director, Dr. Helen B. Fraser, resigned to accept a similar post with the Kentucky State Department of Health at Lexington. Prior to becoming a member of the staff of the Man Memorial Hospital, Dr. Boysen engaged in private practice at York, Pa.

Society News.—The West Virginia Academy of Ophthalmology and Otolaryngology in June elected the following officers for the coming year: president, Dr. Nime K. Joseph, Wheeling; president-elect, Dr. John A. B. Holt, Charleston; vice-president, Dr. William K. Marple, Huntington; secretary-treasurer, Dr. Albert C. Esposito, Huntington; director for two years, Dr. James T. Spencer Jr., Charleston. The next meeting will be Aug. 20-23 at the Greenbrier Hotel, White Sulphur Springs.——The officers elected by the West Virginia State Society of Allergy for 1959-1960 are: president, Dr. Sarah L. C. Stevens, Huntington; vice-president, Dr. Marshall J. Carper, Charleston; and secretary-treasurer, Dr. Merle S. Scherr, 803 Atlas Building, Charleston, W. Va.

MISSISSIPPI

Surgeons Meeting in Gulfport.—The Mississippi Chapter of the American College of Surgeons will meet at the Edgewater Hotel Sept. 11-12 at Gulfport. All members of the medical profession are invited. A panel of Dr. Henry W. Scott Jr., Nashville, Tenn.; Dr. Oscar Creech, New Orleans; Dr. James D. Hardy, Jackson; and Dr. Mark C. Wheelock, Chicago, is planned. For information, write Dr. Archibald C. Hewes, president, Mississippi Chapter, American College of Surgeons, Hewes Building, Gulfport, Miss.

MISSOURI

Dr. Wilson Comes to Columbia.—Dr. Vernon E. Wilson, acting dean of the University of Kansas School of Medicine, Kansas City, has been appointed dean of the School of Medicine at the University of Missouri, Columbia. Dr. Wilson will assume his duties Nov. 1. He will succeed Dr. Gwilym S. Lodwick, who has been acting dean of the School of Medicine since Dr. Roscoe L. Pullen resigned the deanship on March 24. Dr. Wilson, chairman of the Governor's Advisory Committee on State Institutions (Kansas), went to the University of Kansas to be assistant dean of the School of Medicine and assistant professor of pharmacology in 1953. In 1957 he was promoted to associate dean and on May 15 of this year, he was appointed acting dean of the School of Medicine and acting director of the University of Kansas Medical Center, to serve until Oct. 15.

NEW HAMPSHIRE

Dr. Weiss Named Psychiatry Chairman.—Dr. Robert J. Weiss assumed the position of professor and chairman of the department of psychiatry, Dartmouth Medical School, Hanover, effective July 1. He resigned his positions in the department of psychiatry, College of Physicians and Surgeons, Columbia University and the Presbyterian Hospital, New York City.

NEW JERSEY

Personal.—Dr. John J. Butler was appointed director of medical education at St. Michael's Hospital, Newark, and associate professor in the department of medicine, Seton Hall College of Medicine and Dentistry. Dr. Butler was formerly director of medical education at St. Mary's Hospital, Rochester, N. Y.——Dr. Selman A. Waksman, co-discoverer of streptomycin and Nobel Prize winner, has retired as director of the Rutgers Institute of Microbiology.

NEW YORK

New York City

Break Ground for New Hospital.—Groundbreaking for the new University Hospital of New York University's medical center took place July 7. Official ceremonies for the founders and friends of the hospital will take place in September. The new 19-story, 600-bed general hospital, to replace the present University Hospital at 303 E. 20th St., will contain a number of special institutes and pavilions—among them the Institute of Neuromuscular Diseases (provided by the Sister Elizabeth Kenny Foundation), the Institute of Reconstructive Plastic Surgery (provided by the Society for the Rehabilitation of the Facially Disfigured), the William J. Wollman Memorial Pavilion for Children, the Lila Motley Radiation Pavilion, the Louis Altschul Cardiac and Hypertension Clinic, the Irvington House Institute for Rheumatic Fever and Allied Diseases, the Milton B. Rosenbluth Diagnostic Clinic, the Julius S. Rippel Laboratories, and the Alfred P. Sloan Radioisotope Laboratory. Construction of the hospital will complete the NYU-Bellevue Medical Center 50-million-dollar development program started in 1948.

Personal.—Dr. Leonard Greenburg, commissioner of the New York City Department of Air Pollution on Control, was elected president of the Air Pollution Control Association.——Dr. Abraham Jablons was elected president of the Alumni Association of the State University of New York Downstate Medical Center in Brooklyn.——Dr. Harvey J. Tompkins, director of the division of psychiatry, St. Vincent's Hospital, was elected president of the Academy of Religion and Mental Health.

Hospital News.—Dr. Ponciano D. Manalo, of Manila, Philippines, was awarded the $500 Travel Fellowship of the Department of Plastic Surgery at the Mount Sinai Hospital, New York City.——Dr. Joseph E. Mule was appointed director of surgery at Saint John's Episcopal Hospital, Brooklyn. Dr. Mule, who received his M.D. at the University of Rome Medical School in 1940, has been on staff of Saint John's Episcopal Hospital since June 30, 1947, and founded the Tumor Registry (accredited by the American College of Surgeons) in 1954. He succeeds Dr. Clarence Dennis, Brooklyn, who recently resigned.

Fellowships for Tuberculosis Research.—Fellowships and grants amounting to $100,000 are being offered by the New York Tuberculosis and Health Association under its recently expanded research program. One of its grants is the James Alexander Miller Fellowship, named in honor of the physician who was one of the organizers and first president of the association. Carrying a stipend of $7,000 to $10,000 depending on need, this fellowship is offered to a "highly qualified" investigator to enable him to pursue research work anywhere in the United States in a field of interest of the association. Candidates who do not receive the Miller Fellowship may be awarded a fellowship carrying a smaller stipend. Priority for these fellowships is given to New York City area applicants. In addition, the association offers grants for the support of the work of established researchers whose studies have a potential relationship to the problems of tuberculosis. The work must be in medicine, sociology, epidemiology, or the basic sciences, and the project must be conducted in an approved university, hospital, or other institution in the New York City area. Applications for fellowships must be made by Nov. 15, while those for grants-in-aid are due at least six months prior to the date when the contemplated project is scheduled to start. Forms may be obtained by writing the New York Tuberculosis and Health Association, 260 Park Ave. South, New York 10.

OREGON

Personal.—Dr. Robert G. Pittenger, Portland, is the new director of the Pacific Northwest Regional Blood Program, succeeding Dr. Bernard Pirofsky, who resigned his post recently to join the staff at the University of Oregon Medical School.——Dr. John A. Benson Jr., recently on the faculty in the department of medicine at Harvard Medical School, Boston, will become associate professor of medicine and head of the division of gastroenterology, University of Oregon Medical School, Portland. He will replace Dr. George B. Long, Portland physician, who has been acting head of the division on a part-time basis for several years. Dr. Long will remain on the faculty as an associate clinical professor.

TENNESSEE

Tennessee Valley Assembly.—On Sept. 28-29, the Tennessee Valley Medical Assembly will be held at the Read House, Chattanooga, sponsored by the Chattanooga and Hamilton County Medical Society. The program includes 17 scheduled papers, among which is "The Decisive Edge," by Dr. Louis M. Orr, Orlando, Fla., president, American Medical Association. Speaker at the banquet, Sept. 28, 7 p. m., will be Dr. Morris Fishbein, professor emeritus (Rush) University of Illinois, College of Medicine, Chicago, who will present "Medicine and the Changing Social Order." Registration fee ($15, payable to Tennessee Valley Medical Assembly) should be sent to Chattanooga Convention and Visitors Bureau, 819 Broad St., Chattanooga, Tenn. The program is approved for category I credit for members of the American Academy of General Practice.

University News.—At the invitation of the department of surgery, Meharry Medical College, Nashville, Dr. George T. Pack, of New York City, delivered the 12th annual Hale–McMillan Lecture April 30. The subject of this lecture was "Sarcomas of the Soft Somatic Tissues."——Feodor Lynen, Ph.D., a biochemist, from Munich, Germany, was the guest of Meharry Medical College March 26-28. His visit was made possible through the courtesy of the Squibb Centennial Lecture Committee.

TEXAS

Southwest Cancer Conference.—The 13th annual Southwest Regional Cancer Conference, sponsored by the Tarrant County Medical Society and the Tarrant County Unit, American Cancer Society, will be held Sunday, Sept. 20, at the Fort Worth Academy of Medicine. Speakers will include, Dr. Shields Warren, professor of pathology, Harvard University; Dr. Eugene P. Pendergrass, professor of radiology, University of Pennsylvania, and Dr. Warren H. Cole, professor of surgery, University of Illinois. For information, write the American Cancer Society, Tarrant County Unit, 264 West 11th St., Ft. Worth, Texas.

UTAH

New Address.—The Utah Tuberculosis and Health Association announced that its new address is Inland Building, 1941 S. 11th E., Salt Lake City 5, Utah (Telephone: INgersoll 6-9101).

VERMONT

University News.—A Ph.D. program in the University of Vermont College of Medicine department of pharmacology has been approved by the university trustees. It is anticipated the program will become effective during the fall of 1959. It becomes the second Ph.D. program at the university.

WEST VIRGINIA

Dr. Boysen Named Child Health Director.—Dr. Theophilus H. Boysen, III, chief of obstetrics and gynecology at Man Memorial Hospital in Man since 1956, accepted an appointment as full-time director of the division of maternal and child health of the State Department of Health. The office in the State Department of Health has remained vacant since Nov. 16, 1956, when the then director, Dr. Helen B. Prior to becoming a member of the staff of the Man Memorial Hospital, Dr. Boysen engaged in private practice at York, Pa.

Society News.—The West Virginia Academy of Ophthalmology and Otolaryngology in June elected the following officers for the coming year: president, Dr. Nime K. Joseph, Wheeling; president-elect, Dr. John A. B. Holt, Charleston; vice-president, Dr. William K. Marple, Huntington; secretary-treasurer, Dr. Albert C. Esposito, Huntington; director for two years, Dr. James T. Spencer Jr., Charleston. The next meeting will be Aug. 20-23 at the Greenbrier Hotel, White Sulphur Springs.——The officers elected by the West Virginia State Society of Allergy for 1959-1960 are: president, Dr. Sarah L. C. Stevens, Huntington; vice-president, Dr. Marshall J. Carper, Charleston; and secretary-treasurer, Dr. Merle S. Scherr, 803 Atlas Building, Charleston, W. Va.

Personal.—Dr. Edward J. Van Liere, Morgantown, dean of the West Virginia University School of Medicine, has been elected an affiliate of the Royal Society of Medicine, London, England. The society was founded in 1805 and chartered in 1834.——Dr. Robert P. Hagerman, recently retired from service with the Department of Justice, has been named by Dr. Richard J. Lilly, head of the West Virginia State Department of Mental Health, as superintendent of Weston State Hospital. He succeeds Dr. Lilly, who has served as superintendent during the past several months.

WYOMING

State Medical Election.—Elected officers of the Wyoming State Medical Society are: Drs. Benjamin Gitlitz, Thermopolis, president; Francis A. Barrett, Cheyenne, president-elect; S. J. Giovale, Cheyenne, vice-president; Frederick H. Haigler, Casper, secretary; Carleton D. Anton, Sheridan, treasurer; Albert T. Sudman, Green River, delegate to A. M. A.; and Bernard J. Sullivan, Laramie, alternate delegate to A. M. A.

GENERAL

Change of Address.—Mail intended for the Joint Commission on Mental Illness and Health, its officers, or its staff should be addressed as follows: Joint Commission on Mental Illness and Health, Massachusetts Mental Health Center, 74 Fenwood Road, Boston 15. Following conclusion of the study projects of the National Mental Health Survey on June 30, editorial offices will be maintained at the new address until publication work on the monograph series and final report is complete.

Books for Philippine Medical Library.—A request for medical books and journals from A. M. A. members has been received from Dr. Mercedes V. Planas, of Cebu City, Philippines, for the Cebu Medical Library. The organization, "Books for Asian Students," has agreed to handle the shipping. Publications should be shipped by motor freight, collect (not Railway Express or moving van). The shipment should be addressed to Cebu Medical Library, % Books for Asian Students, 21 Drumm St., San Francisco 11, Calif. Packing in ordinary cardboard cartons tied with rope is sufficient. Packages will be repacked for overseas shipment. Dr. Planas' address is P. O. Box 55, Cebu City, Philippines.

Physicians to Tour Russia.—Six American physicians will begin an exchange mission to Russia on Sept. 5, from Helsinki, Finland. They are Drs. Clifford J. Barborka, Chicago; William B. Castle, Boston; James Murray Luck, Palo Alto, Calif.; Currier McEwen and William H. Sebrell Jr., of New York City; and Floyd S. Daft, of Bethesda, Md. The tour will proceed first to Moscow to visit medical institutes and laboratories and then start a month-long itinerary which will include Leningrad, Sochi, Sukhumi, Kiev, and Odessa. Dr. Barborka, president, American Gastroenterology Association, is taking a previous tour to coordinate a program of medical researches in gastroenterology, which will take him to Sweden, France, Spain, the Netherlands, Germany, England, and Switzerland.

Otorhinolaryngological Congress in Paris.—The 57th French Congress of Otorhinolaryngology will take place Oct. 19-22 in the Grand Amphitheater of the Faculty of Medicine, rue de l'Ecole de Médecine, under the presidency of Dr. Andre Soulas, of Paris, and the honorary presidency of Prof. L. Binet, dean of the Faculty of Medicine of Paris. The program includes presentation of papers, and two reports will be discussed: (1) Surgery for Deafness—Its Present State, Its Future, and (2) The Laryngologist and Actual Data on Treatment of Acute Respiratory Insufficiencies. An exposition of surgical instruments, appliances, and pharmaceutical specialties will be held in the Hall of the Faculty. For information, write the General Secretary, Dr. Henry Guillon, 6, Avenue MacMahon, Paris 17, France.

Research Fellowships and Grants.—The Life Insurance Medical Research Fund is receiving applications for two types of awards to be available July 1, 1960, as follows: (1) Until Oct. 15, 1959, for postdoctoral research fellowships. Candidates may apply for support in any field of the medical sciences. Preference is given to those who wish to work on fundamental problems, especially those related to cardiovascular function or disease. Minimum stipend is $4,500 with allowances for dependents and necessary travel. (2) Until Nov. 1, 1959, for grants to institutions in aid of research on cardiovascular problems. Support is available for physiological, biochemical, and other basic work broadly related to cardiovascular problems as well as for clinical research in this field. Information and application forms may be obtained from the Scientific Director, Life Insurance Medical Research Fund, 345 E. 46th St., New York 17.

Occupational Health Congress in New York.—The 13th International Congress on Occupational Health will be held July 25-29, 1960, at the Hotel Waldorf-Astoria, New York City, organized under the auspices of the International Association on Occupational Health. The program will include physicians, nurses, industrial hygienists, and representatives from more than 40 countries. The following aspects on occupational health will be considered: administrative methods, medical and surgical practices, education and training, social and legal aspects, work physiology and psychology, environmental factors in health, environmental hygiene, and hazards of specific industries. Persons who wish to present papers at the congress should obtain information by writing Dr. Irving R. Tabershaw, Chairman of the Scientific Program Committee, International Congress on Occupational Health, 375 Park Ave., New York City.

Medical Writers' Meet in St. Louis.—The 16th annual meeting of the American Medical Writers' Association will be held at the Chase Hotel, St. Louis, Oct. 2-3, under the presidency of Dr. Morris Fishbein, Chicago. There will be morning, afternoon, and evening sessions on Oct. 2 and a four-hour conference on medical writing the morning of Oct. 3, under the chairmanship of Dr. William D. Snively Jr., of Evansville, Ind. The conference will comprise three sections: Technical Aspects of Medical Writing, Contributions of Other Arts and Sciences to Medical Writing, and Technical Aspects of Publishing and Editing. Over 30 speakers are on the program. A complete program may be obtained from Dr. Harold Swanberg, Secretary, W. C. U. Building, Quincy, Ill. (The meeting will be preceded by the 24th annual meeting of the Mississippi Valley Medical Society at the Chase Hotel, Sept 29-Oct. 1.)

Surgeon Wins Golf Tournament.—Dr. Gerald F. Dederick Jr., Hackensack, N. J., surgeon, won top honors at the American Medical Golfing Association 43rd annual tournament with a low gross total of 69. About 200 physicians teed off in the tourney which was played on two courses at the Seaview Country Club. For Dr. Dederick, it was a repeat performance, since he topped the physician-golfers at the tournament which was held in conjunction with the 1954 A. M. A. annual meeting in Atlantic City. Dr. James O. Smith, general practitioner of Clinton, Mo., had a low net championship with a 64. He shot an 80 and had a 16 handicap. In the senior class (60 and over) Dr. Edward J. Kempf, Wading River, N. Y., shot 81 for low gross honors. Dr. Paul E. Reeves, Scottsville, N. Y., and Francis L. McNelis, Providence, R. I., were winners in the Calloway (undetermined handicap) class. Dr. James C. McLaughlin, Philadelphia, was succeeded as president of the association by Dr. John A. Growden, of Kansas City.

Grants-in-Aid for Nutrition Research.—The National Vitamin Foundation wishes to bring to the attention of those engaged in clinical and basic research in nutrition, biochemistry, and metabolism its current major interest "in the support of research, preferably on man, most likely to advance our understanding of the diverse metabolic functions of the vitamins." Research on vitamin nutrition and metabolism in the areas of (1) mental health and (2) skin eruptions related to drug ingestion and allergies is encouraged, and applications for grants-in-aid of such research from interested and qualified investigators are invited. Application forms may be obtained from the offices of the foundation at 149 E. 78th St., New York 21, N. Y. The foundation takes action on applications twice a year, in the spring and fall. For grants to be effective July 1, applications should be mailed to the foundation before the preceding March 1; for January grants, applications should be in the possession of the foundation by Sept. 15.

Second World Conference on Medical Education.—Medical educators from 55 different countries will take part in the Second World Conference on Medical Education in Chicago, Aug. 20-Sept. 4. The conference is being held under the auspices of the World Medical Association. The collaborating groups include the World Health Organization, the Council for International Organizations of Medical Sciences, and the International Association of Universities. There will be 125 speakers. Russia is expected to send a delegation to the conference and will have at least two speakers on the program. Poland, another nonmember of the W. M. A., will also send representatives. Dr. Raymond B. Allen, chancellor, University of California, Los Angeles, president of the conference, said, "It is the purpose of this Second World Conference on Medical Education to pass on to the young in mind and heart the experience and learning of the ages. In that way we are advancing the welfare of all mankind regardless of political differences, race, and creed." Dr. Victor Johnson, Rochester, Minn., is deputy president of the conference.

Funds for Health Education.—The National Foundation announced allocations of more than one million dollars in March of Dimes funds for education in the health professions, including an appropriation for a new fellowship program "to give doctors more extensive clinical training in the fields of rheumatology and birth defects." Awards for education in the health fields are in addition to grants made for the same period in research and clinical investigation. The combined sum awarded is more than $3,500,000. The first 515 winners of a health scholarship program initiated earlier this year to provide four-year college training for young Americans in medicine, nursing, physical therapy, medical social work, and occupational therapy will be announced this summer. The fellowship program recently announced is open to residents or practicing physicians for study in rheumatology or in the treatment of patients suffering from birth defects of the central nervous system. Fellowships will be awarded for a minimum period of one year but are subject to renewal. Stipends will range from $3,600 to $7,000 a year. More than $900,000 of the educational grants announced today will go to universities, institutions, and professional associations to support the teaching and recruitment programs.

Dietetic Meeting in Los Angeles.—The 42nd annual meeting of the American Dietetic Association will be held Aug. 25-28 at the Shrine Auditorium, Los Angeles. Staff conferences and meetings will precede the annual meeting. Panel discussions are planned as follows: "A Look at Atherosclerosis Today," with Dr. Laurence W. Kinsell, Oakland, Calif., coordinator; "Spectrums in Various Nursing Programs Today," Miss Marjorie E. Newton, San Francisco, moderator; "What Are Your Needs in Food Packaging and Processing?" Lendal H. Kotschevar, Ph.D., Missoula, Mont., moderator; and "Opportunities for Social Science Research in Dietetics," Edward Wellin, Ph.D., New York City, coordinator. Discussions will also be given under the general title, "Share and Compare," at which several papers will be presented, with one session to be presented each day. Films, exhibits, and group discussions are planned. The annual banquet will be held Aug. 27 at the Statler Hilton Hotel. For information write Miss Ruth M. Yakel, 620 N. Michigan Ave., Chicago 11, Executive Secretary.

Society News.—At the meeting of the **Society for Investigative Dermatology** June 6-7, the following officers were elected: Dr. Thomas B. Fitzpatrick, Portland, Ore., president; Dr. Harvey Blank, Miami, Fla., vice-president; Drs. Thomas H. Sternberg, Los Angeles, and Eugene J. VanScott, Bethesda, Md., appointed to board of directors.——The following officers of the **American College of Chest Physicians** were elected for the year 1959-1960: president, Dr. Seymour M. Farber, San Francisco; president-elect, Dr. Mathew J. Flipse, Miami, Fla.; first vice-president, Dr. Hollis E. Johnson, Nashville, Tenn.; second vice-president, Dr. John F. Briggs, St. Paul, Minn.; treasurer, Dr. Charles K. Petter, Waukegan, Ill.; and assistant treasurer, Dr. Albert H. Andrews, Chicago.——The newly elected officers of the **American Neurological Association** are: president, Dr. Derek Denny-Brown, Boston; president-elect, Dr. Harold G. Wolff, New York; first vice-president, Dr. Charles Rupp Jr., Philadelphia; second vice-president, Dr. Samuel Brock, New York; secretary-treasurer, Dr. Melvin D. Yahr, 710 W. 168th St., New York 32; and assistant secretary, Dr. Clark H. Millikan, Rochester, Minn.

Symposium on Tuberculosis Prevention.—A Symposium on the Prevention of Tuberculosis in Children will be held Thursday, Nov. 12, 2 p. m., in the New York Academy of Medicine Building, 2 E. 103rd St., New York City. The Tuberculosis Preventorium for Children at Farmingdale, N. J., is celebrating its 50th anniversary this year, and the symposium, for those interested in the prevention of tuberculosis from a professional and laymen's point of view, is one of the events planned by the 50th Anniversary Committee. Dr. James E. Perkins, New York City, managing director, National Tuberculosis Association, will serve as moderator. Dr. Herbert R. Edwards, associate professor of public health and medicine, Yale University School of Medicine, New Haven, Conn., will discuss "The Role of a Health Department." Dr. Arvid J. Wallgren, emeritus professor of pediatrics, Royal Caroline Medical School, Stockholm, Sweden, will speak on BCG vaccination, and Mrs. Shirley H. Ferebee, associate chief, operational research, tuberculosis program of the U. S. Public Health Service, will discuss chemoprophylaxis. This symposium has been arranged by Dr. Edith M. Lincoln, former head of the Children's Chest Clinic at Bellevue Hospital and a member of the Preventorium Medical Board.

National Association Meeting in Detroit.—The 64th convention of the National Medical Association will be held in Detroit, Aug. 10-13, with the Detroit Medical Society and associated committees as host. Headquarters will be the Sheraton-Cadillac Hotel. Dr. R. Stillmon Smith, Macon, Ga., president of the association, will present and address at the opening session, Aug. 11. A symposium, "Genetics in Modern Medicine," will be given at a joint session, Aug. 11, and the section meetings will include the following symposiums and moderators:

The Current Place of Adrenal Cortical Steroids in Medical Practice, Dr. Walter L. Henry Jr., Washington, D. C.
Recent Advances in the Diagnosis and Treatment of Rheumatic and Collagen Diseases, Dr. Everett N. Rottenberg, Detroit.
Newer Trends in the Diagnosis and Treatment of the Common Anemias, Dr. Allison B. Henderson, Detroit.
Recent Advances in the Diagnosis and Treatment of Peripheral Vascular Insufficiency, Dr. Homer M. Smathers, Detroit.
Recent Advances and Management of Congestive Heart Failure, Dr. William Gibson, Detroit.
Some Practical Approaches to the Diagnosis and Management of Pulmonary Insufficiency, Dr. Audley R. Mamby, Chicago.
Newer Concepts in Ophthalmology and Otolaryngology, Dr. Howard P. Venable, St. Louis.
Carcinoma of the Uterus, Dr. William F. Goins, Detroit.
The Importance of Early Diagnosis—Cancer, Tuberculosis, Venereal Diseases, Dr. Edith Irby Jones, Hot Springs National Park, Ark.

A clinical pathology conference is planned for Aug. 13. Round-table discussions, panel discussions, and scientific and technical exhibits are planned. There is no registration fee. A ladies' program is arranged. For information, write Dr. John T. Givens, 1108 Church St., Norfolk, Va., Secretary.

Rehabilitation Fellowship for Latin American.—The World Rehabilitation Fund in cooperation with the International Society for the Welfare of Cripples announced the creation of the Bell Greve Memorial Fellowship, created to honor the memory of the late Miss Bell Greve, Cleveland, who for many years served as secretary-general, International Society for the Welfare of Cripples. The Bell Greve Memorial Fellowship will be given to a trainee from Latin America for a minimum of one year's training in rehabilitation in the United States. The fellowship may be given to a physician, physical therapist, occupational therapist, prosthetist, orthotist, speech and hearing therapist, or rehabilitation counsellor. Miss Greve headed a Red Cross child health center in Czechoslovakia and then moved to Armenia to run an orphanage caring for 4,500 children. After World War I she took a leave of absence as director of the Cleveland Rehabilitation Center to join the staff of UNRRA to establish a rehabilitation service in Greece. At the time of her death in 1957, she was director of public health and welfare, City of Cleveland. Information concerning applications for the Bell Greve Memorial Fellowship may be secured by writing the International Society for the Welfare of Cripples, 701 First Ave., New York 17, or the World Rehabilitation Fund, 400 E. 34th St., New York 16.

Hospital Meeting in New York.—The 61st annual meeting of the American Hospital Association will be held Aug. 24-27, in the New York City Coliseum. General assembly speakers will include Dr. Marcolino G. Candau, Switzerland, director-general of the World Health Organization; Mr. Elmo Roper, public opinion analyst; Mr. Francis Boyer, chairman of the board of Smith Kline and French Laboratories; and Dr. Alexander D. Langmuir, Atlanta, Ga., chief, Epidemiology Branch, Communicable Disease Center, U. S. Public Health Service. Sessions will cover such topics as providing and financing health care for the aged, future of prepayment plans for hospital care, progressive patient care, governing board's responsibility for medical care in the hospital, auxiliary and the hospital service story, evaluating in-hospital volunteer services, hospital school of nursing education, and the hospital and allied health professions. There will be 36 instructional sessions concerned with specific phases of hospital operation. Dr. Leona Baumgartner, commissioner of health for New York City, will speak at the Auxiliary's breakfast Aug. 24, with Dr. Francis J. Braceland, psychiatrist-in-chief, Institute of Living, Hartford, Conn., speaking at the luncheon Aug. 26. General Alfred M. Gruenther, president, American National Red Cross, will be the speaker for the Federal Hospital Executives Luncheon Aug. 25. An International Dinner and the President's Luncheon are scheduled. Allied groups meeting in conjunction with the association's annual meeting will be the American Association of Hospital Consultants, Aug. 22; the American Association for Hospital Planning, Aug. 22-23; the American College of Hospital Administrators, Aug. 22-24; and the American Association of Nurse Anesthetists, Aug. 24-27. About 500 exhibits of new equipment and supplies and educational displays are planned.

Prevalence of Poliomyelitis.—According to the National Office of Vital Statistics, the following number of reported cases of poliomyelitis occurred in the United States, its territories and possessions in the weeks ended as indicated:

Congress on Obstetrics and Gynecology.—On Sept. 19-22, a Congress on Gynecology and Obstetrics will be held in Lisbon. The program will include an international meeting of the Portuguese Society of Obstetrics and Gynecology, Sept. 19-20. Subjects for Sept. 19 include "Problems of Diagnosis Presently in Discussion in Relation to Cancer of the Uterus (Cervix and Endometrium)" and "Prophylaxis of Abortion." The fourth congress of the International Professional Union of Gynecology and Obstetrics will be held Sept. 21-22, with the opening session at the Santa Maria Hospital. Two discussions will be devoted to the detection of genital cancer of women from the economic and social point of view. Other themes include "Criterion and Procedures of the Specialization of Gynecology and Obstetrics" and "Economic Classification of Fees and Actions in Obstetrics and Gynecology According to a Scale of Values." A general assembly is planned for 5 p. m., Sept. 22, with the banquet planned for that evening at 8:30 p. m. A ladies' program and a schedule of tours are arranged.

Postpone Congress of Nephrology.—The organizing committee of the first International Congress of Nephrology has announced that it has been obliged to postpone the congress to Sept. 1-3, 1960. The congress was originally scheduled to be held Sept. 3 (in Geneva), and September 4-5 (in Evin), 1959.

EXAMINATIONS AND LICENSURE

MEDICAL SPECIALTY BOARDS

American Board of Anesthesiology: *Written.* Various locations, July 8, 1960. Final date for filing application is January 8. Sec., Dr. Forrest E. Leffingwell, 217 Farmington Ave., Hartford 5, Conn.

American Board of Dermatology: *Written.* Several Cities, Oct. 5. *Oral.* Oklahoma City, Jan. 15-18, 1960. The final date for filing all applications was July 1, 1959. Sec., Dr. Beatrice M. Kesten, One Haven Ave., New York 32.

American Board of Internal Medicine: *1959 Schedule—Written,* Oct. 19. Final date for filing application was May 1. *Oral.* For candidates on the West Coast, Portland, Ore., Sept. 9-12. Final date for filing application was March 1. *Oral.* For candidates on the East Coast, Nov. 6-7, 9-10. Final date for filing application was March 1. Sec.-Treas., Dr. William A. Werrell, One West Main St., Madison 3, Wis.

American Board of Neurological Surgery: Examination given twice annually, in the spring and fall. In order to be eligible a candidate must have his application filed at least six months before the examination time. New Haven, Nov. 14-16. Sec., Dr. Donald D. Matson, 300 Longwood Ave., Boston, Mass.

American Board of Obstetrics and Gynecology: Applications for certificates, new and reopened, Part I, and requests for re-examination Part II are now being accepted. *Part I. Written.* Jan. 15, 1960. All candidates are urged to make such application at the earliest possible date. Deadline date for receipt of applications is August 1, 1959. No applications can be accepted after that date. Sec., Dr. Robert L. Faulkner, 2105 Adelbert Road, Cleveland 6, Ohio.

American Board of Ophthalmology: *Oral.* St. Louis, Oct. 6-10. *Written.* January 1960 in various cities. Applications for the 1960 written examination must be filed before July 1. *Oral.* 1960, San Francisco, May; Chicago, October. Sec., Dr. Merrill J. King, Box 236, Cape Cottage Branch, Portland, Maine.

American Board of Orthopaedic Surgery: *Part II.* Chicago. Jan. 19-21, 1960. The deadline for the receipt of application is Aug. 15, 1959. Sec., Dr. Sam W. Banks, 116 South Michigan Ave., Chicago 3.

American Board of Otolaryngology: *Oral.* Chicago, Oct. 5-9. Final date for filing application was April 1. Sec., Dr. Dean M. Lierle, University Hospitals, Iowa City.

American Board of Pathology: New Orleans, Nov. 12-14. Final date for filing application is October 1. Sec., Dr. Edward B. Smith, Indiana University Medical Center, 1100 W. Michigan St., Indianapolis 7.

American Board of Pathology: *Examination in Forensic Pathology.* New Orleans, Nov. 13. Final date for filing application is October 1. Sec., Dr. Edward B. Smith, Indiana University Medical Center, 1100 W. Michigan St., Indianapolis 7.

American Board of Pediatrics: *Written.* January 1960. Exec. Sec., Dr. John McK. Mitchell, 6 Cushman Road, Rosemont, Pa.

American Board of Plastic Surgery: *Oral and Written.* Miami, Fla., Oct. 15-17. Final date for submitting case reports is July 1. Corresponding Secretary, Miss Estelle E. Hillerich, 4647 Pershing Ave., St. Louis 8, Mo.

American Board of Proctology: *Oral and Written.* Philadelphia, September. Final date for filing application was March 15. Sec., Dr. Stuart T. Ross, 520 Franklin Ave., Garden City, N. Y.

American Board of Psychiatry and Neurology: Chicago, Oct. 19-20; New York, Dec. 14-15; San Francisco, Mar. 14-15, 1960. Training credit for full time psychiatric and/or neurologic assignment in unapproved military programs or services between the dates of Jan. 1, 1950 and Jan. 1, 1954 was terminated on Jan. 1, 1959. Sec., Dr. David A. Boyd, 102-110 Second Ave. S. W., Rochester, Minn.

American Board of Radiology: *Examination.* Washington, Dec. 6-9. Deadline for filing application is July 1. Candidates examined in Diagnostic Roentgenology may expect to be examined in Physics. Obligatory examination in Nuclear Medicine has been postponed until after June 30, 1962 for those candidates being examined in Radiology or Therapeutic Radiology. Until that time the examination in Nuclear Medicine will be optional for those who wish to be examined in Radiology or Therapeutic Radiology. Sec., Dr. H. Dabney Kerr, Kahler Hotel Bldg., Rochester, Minn.

American Board of Surgery: *Written* examinations (Part I) will be held on December 2, 1959 at various centers to be announced later. Candidates are urged to apply several months before completion of training requirements although the closing date for filing applications is August 1. Those completing training requirements after September 30 cannot be considered for the Part I examination in December of the same year. Sec., Dr. John B. Flick, 1617 Pennsylvania Blvd., Philadelphia 3.

Board of Thoracic Surgery: *Written.* Various centers throughout the country, September 1959. Final date for filing application was July 1. *Oral.* September. Final date for filing application was July 1. Sec., Dr. William M. Tuttle, 1151 Taylor Ave., Detroit 2, Mich.

American Board of Urology: *Written.* Approximately 25 cities throughout the country, December 4, 1959. *Oral-Clinical* and *Examination in Pathology.* Chicago, February 1960. Final date for filing application is Sept. 1, 1959. Sec., Dr. William Niles Wishard, 30 Westwood Rd., Minneapolis 26, Minn.

DEATHS

Abbott, Charles Franklin Ⓜ Syracuse, N. Y.; College of Physicians and Surgeons, Baltimore, 1903; for many years practiced in Elmira, where he was on the staffs of St. Joseph's and Arnot-Ogden hospitals, and associated with the Pennsylvania Railroad; died in the General Hospital May 2, aged 83.

Alexander, Horace Quincy, Russells Point, Ohio; Pulte Medical College, Homeopathic, Cincinnati, 1897; served as mayor; for many years justice of the peace of Washington Township; died in Sarasota, Fla., May 10, aged 88.

Baird, Perry Cossart Jr., Detroit, Mich.; Harvard Medical School, Boston, 1928; served on the faculty of his alma mater; formerly on the staff of the Peter Bent Brigham Hospital in Boston; died May 4, aged 55.

Baker, Robert E. Ⓜ Orleans, Ind.; University of Louisville (Ky.) Medical Department, 1892; member of the American Academy of General Practice; died May 3, aged 97.

Balaban, Joseph S., Boston; University of Istanbul Medical Faculty, Turkey, 1919; for many years medical examiner for the Irish-American Athletic Association, sponsor of amateur fights; died in the Pratt Diagnostic Hospital May 11, aged 69.

Bone, Oscar Lasley, Newark, Ark.; Memphis (Tenn.) Hospital Medical College, 1908; died May 18, aged 74.

Boyes, Henry Robert Ⓜ Detroit; Detroit College of Medicine and Surgery, 1916; during World War I served in France with the American Expeditionary Force; for many years medical missionary in the Middle East, serving as director of the Kennedy Memorial Hospital of the Presbyterian Church in Tripoli, Lebanon, from 1921 until May, 1958; in 1946 received the Gold Medal of the Lebanese Order of the Cedar for his medical services to the people of the nation; died in the Harper Hospital May 9, aged 69.

Brazda, Adolph William Ⓜ Ranger, Texas; born in Dodge, Neb., Jan. 11, 1899; Emory University School of Medicine, Atlanta, 1929; past-president of the Eastland County Medical Society; member of the American Trudeau Society, Southern Medical Association, Association of Military Surgeons of the United States, New York Academy of Science, Texas Academy of Science, Phi Chi Medical Fraternity, and the American Association for the Advancement of Science; received the "Certificate of Merit" in 1958, an international award, for the outstanding paper in the International Academy of Proctology, of which he was a fellow; city health officer for Ranger for three terms; member of the American Legion and the Veterans of Foreign Wars; veteran of World War II, received the EAME Campaign Medal with two Battle Stars; in 1956 promoted to lieutenant colonel in the U. S. Air Force Reserve and retired in January, 1959; a Ranger General Hospital board member for six years, serving one term as board chairman; past-president of the Ranger Rotary Club; died May 20, aged 60.

Brent, Charles Maurice Ⓜ Niagara Falls, N. Y.; born in Mahone Bay, N. S., Canada, Jan. 27, 1904; University of Buffalo School of Medicine, 1929; member of the Radiological Society of North America; past-president and secretary of the Niagara County Medical Society; past-president of the Niagara Academy of Medicine; for three terms president of the board of education, of which he became a member in 1948; from 1939 to 1950 served on the board of directors of the Niagara County Tuberculosis and Health Association; member and past-president of the staff of Mount St. Mary's Hospital, where he died May 3, aged 55.

Briggs, Edward Fitch Ⓜ Truro, Mass.; Baltimore Medical College, 1906; fellow of the American College of Surgeons; veteran of World War I; served on the staff of the Northern Westchester Hospital in Mount Kisco, where he was instrumental in organizing the medical board; died May 21, aged 75.

Briggs, Guy Young, St. Louis; Washington University School of Medicine, St. Louis, 1908; served on the faculty of his alma mater; died in St. John's Hospital May 17, aged 82.

Brown, Frank Eugene, Portland, Ore.; Creighton University School of Medicine, Omaha, 1927; formerly a member of the Portland Boxing Commission; veteran of World War II; served as a member of the medical staff of the Veterans Administration; died in St. Vincent's Hospital May 9, aged 56.

Bruning, Henry Frederick Ⓜ Brooklyn; Columbia University College of Physicians and Surgeons, New York City, 1905; a founder of the Bay Ridge Hospital; on the courtesy staff, department of medicine, Methodist Hospital, where he died May 11, aged 76.

Buczynski, Charles Casimir Ⓜ Chicago; Loyola University School of Medicine, Chicago, 1929; member of the Industrial Medical Association; vet-

---

Ⓜ Indicates Member of the American Medical Association.

eran of World War II and the Korean War; on the staff of the Loretto Hospital; died in St. Mary of Nazareth Hospital May 22, aged 55.

Burkes, De Witt Clinton Ⓜ Portland, Ore.; born March 11, 1887; University of Louisville (Ky.) Medical Department, 1911; specialist certified by the American Board of Psychiatry and Neurology; fellow of the American Psychiatric Association and the Portland Academy of Medicine; fellow and life member of the American College of Physicians; past-president of the Oregon Neuropsychiatric Society; member of the International League Against Epilepsy and the Portland Psychiatrists in Private Practice; for 14 years a member of the Oregon State Board of Health, of which he was vice-president and twice president; past assistant surgeon and surgeon in the U. S. Public Health Service Reserve; veteran of World War I; head of psychiatry at Army Induction Center during World War II; since 1930 clinical associate in psychiatry at the University of Oregon Medical School; medical officer in charge of Veterans Administration at Fort Steilacoon, Wash., from 1921 to 1924 and American Lake, Wash., from 1924 to 1927; staff member, Holliday Park Hospital, Good Samaritan Hospital, St. Vincent's Hospital, and the Morningside Hospital; consultant, Veterans Administration Hospital and the Multnomah Hospital; founder and first president of the Portland Chamber Orchestra; died May 16, aged 72.

Burkhead, Jesse DeWitt Ⓜ Opelika, Ala.; Tulane University School of Medicine, New Orleans, 1920; died in the Wheeler Hospital in La Fayette May 1, aged 65.

Butterfield, Elmore Everest, Long Island City, N. Y.; born in Washington, D. C., in 1881; Columbian University Medical Department, Washington, D. C., 1903; from 1904 to 1906 instructor in pathology at the University of Michigan in Ann Arbor; for the next three years studied at the University of Munich in Germany, where he served as a volunteer assistant in the university's clinical medical institute; under grants from the Rockefeller Institute for Medical Research, worked at the University of Tubingen in Germany and the University of Leiden in the Netherlands; assistant in physics and chemistry at the Rockefeller Institute in New York City from 1911 to 1914; pathological chemist at Bellevue Hospital in New York City, 1914-1915; from 1915 to 1918 pathological chemist and chemist of the central testing laboratory, Bureau of Contract Supervision, City of New York; for many years chemist in charge of physical and the chemical testing laboratory of the Borough of Queens, President's Office, City of New York; died in the Elmhurst (N. Y.) General Hospital May 16, aged 77.

Carter, Henry Rose, Ashland, Va.; University College of Medicine, Richmond, 1897; veteran of the Spanish-American War; died May 13, aged 84.

Charbonneau, Arthur Ames Ⓜ Green Bay, Wis.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1910; veteran of World War I; died May 2, aged 74.

Clark, Lambert Oran Ⓜ Lafayette, La.; Medical Department of Tulane University of Louisiana, New Orleans, 1905; in 1937 was presented with the 1936 civic cup award for outstanding service to the community by the Young Men's Business Club; surgeon in chief and one of the original members of the board of directors of the Lafayette Sanitarium, where he died May 8, aged 79.

Clay, Calvin Ⓜ St. Charles, Mo.; Washington University School of Medicine, St. Louis, 1922; past-secretary of the St. Charles County Medical Society; veteran of World War I; city physician for six years; recently awarded a selective service medal for uncompensated medical service; served as local physician for Missouri, Kansas and Texas Railroad; formerly on the staff of St. Francis Hospital in Washington, Mo.; on the staff of the St. Joseph's Hospital in St. Charles, where he died May 15, aged 64.

Clifford, Robert Henry Ⓜ Detroit; born in Brooklyn Feb. 10, 1915; University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1940; interned at the Union Memorial Hospital in Baltimore, where he served a residency; interned at the Jefferson Hospital in Roanoke, Va.; served a residency at the Presbyterian Hospital in New York City and the Veterans Administration Hospital in New York City; specialist certified by the American Board of Plastic Surgery; fellow of the American College of Surgeons; member of the American Society for Surgery of the Hand and the American Society of Plastic and Reconstructive Surgery; veteran of World War II; physician in charge, division of plastic surgery, Henry Ford Hospital; died in Boston May 15, aged 44, while attending a meeting of the American Association of Plastic Surgeons.

Coleman, John F., Smoaks, S. C.; Medical College of Georgia, Augusta, 1902; died in St. Joseph's Hospital, Savannah, Ga., May 1, aged 83.

Connelly, Leo Augustine, Baldwin, N. Y.; University of Buffalo School of Medicine, 1924; veteran of World War II; served on the staffs of the Cornwall (N. Y.) Hospital and St. Luke's Hospital in Newburgh; died in the Veterans Administration Hospital, Northport, May 2, aged 61.

Cowles, Dwight, Forge Village, Mass.; Tufts College Medical School, Boston, 1913; veteran of World War I; for many years physician for the board of health and school physician in Westford; mill physician of the Abbot Worsted Company of Forge Village; on the courtesy staff of Lowell General Hospital in Lowell, where he died May 15, aged 66.

Cozzens, James Patrick Ⓜ Cleveland; St. Louis University School of Medicine, 1924; supervisor of health service in city public schools; died in the Cleveland Clinic Hospital May 2, aged 61.

Desparois, Guy Bernard Ⓜ Los Angeles; Northwestern University Medical School, Chicago, 1907; on the staff of the Queen of Angels Hospital, where he died May 12, aged 76.

Dorsey, Francis Patrick Jr. Ⓜ Hartington, Neb.; Northwestern University Medical School, Chicago, 1928; past-president of the Cedar–Dakota–Dixon–Thurston–Wayne Counties Medical Society; staff member of Sacred Heart Hospital in Yankton, S. D., and St. Joseph's Hospital in Sioux City, Iowa, where he died May 14, aged 57.

Edlavitch, Baruch Mordecai Ⓜ Fort Wayne, Ind.; Johns Hopkins University School of Medicine, Baltimore, 1910; veteran of World War I; past-president of the Allen County Medical Society; associated with Lutheran and St. Joseph's hospitals, and the Parkview Memorial Hospital, where he died May 18, aged 74.

Fash, James Cone Ⓜ Galesburg, Ill.; University of of Illinois College of Medicine, Chicago, 1940; interned at Missouri Baptist Hospital in St. Louis; served a residency at the Milwaukee County Hospital in Milwaukee and the Methodist Hospital of Central Illinois, Peoria; member of the American Academy of General Practice; veteran of World War II; associated with St. Mary's and Cottage hospitals; died May 11, aged 45.

Fedko, Waldemar Theodore Ⓜ Gordon, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1926; served as secretary of the Pennsylvania Physical Therapy Association; for eight years Schuylkill County coroner; physician for the Schuylkill County Prison in Pottsville; secretary of the staff of Ashland (Pa.) State Hospital; served on the staff of the Frankford Hospital in Philadelphia; past-president of the Ashland Rotary; died in Pottsville (Pa.) Hospital May 13, aged 58.

Feider, Arnold Peter Ⓜ Cleveland, Wis.; Marquette University School of Medicine, Milwaukee, 1944; member of the American Academy of General Practice; veteran of World War II; staff member of the St. Nicholas and Memorial hospitals in Sheboygan and Holy Family and Memorial hospitals in Manitowoc; died in Sheboygan May 9, aged 39.

Fink, Elizabeth Ⓜ Bridgeport, Conn.; Universität Leipzig Medizinische Fakultät, Saxony, Germany, 1923; died May 20, aged 69.

Goldstein, Abraham Ⓜ Lakewood, N. J.; Long Island College Hospital, Brooklyn, 1911; past-president of the Ocean County Medical Society; associated with the Paul Kimball Hospital, where he was past-chief of staff; died May 27, aged 71.

Gonda, Victor Emanuel Ⓜ Palo Alto, Calif.; born in Hungary May 7, 1889; Magyar Királyi Pázmány Petrus Tudományegyetem Orvosi Fakultasa, Budapest, Hungary, 1911; specialist certified by the American Board of Psychiatry and Neurology; member of the American Academy of Neurology, American Psychiatric Association, and the Central Neuropsychiatric Association; past-president of the Chicago Neurological Society; formerly practiced in Chicago, where he was on the faculty of Rush Medical College, Loyola University School of Medicine, and Cook County Post Graduate School; served on the staffs of Cook County Hospital, and Alexian Brothers Hospital in Chicago; associated with the Veterans Administration Hospital; died in the Palo Alto Hospital May 17, aged 70.

Gradwohl, Rutherford B. Hayes Ⓜ St. Louis; born in Baltimore March 4, 1877; Washington University School of Medicine, St. Louis, 1898; member of the American Urological Association and the American Academy of General Practice; in 1954 received an award from the American Academy of Forensic Science, of which he was founder; veteran of World War I; later rose to the rank of commander in the U. S. Naval Reserve; director of the crime laboratory of St. Louis Police Department; for many years director of the Gradwohl School of Laboratory Technique and the Gradwohl Laboratories; formerly instructor of pathologic anatomy at St. Louis University School of Medicine and professor of bacteriology at Barnes Medical College; served as coroner's physician for many years; at one time laboratory director and member of the pathology and bacteriology staffs at St. Louis County Hospital; for many years pathologist at the Christian Hospital; at one time editor of the *Bulletin of St. Louis Medical Society;* author of "Blood and Urine Chemistry" and "Clinical Laboratory Methods and Diagnosis"; died in the Jewish Hospital May 9, aged 82.

Gulledge, John F. Ⓜ Siloam Springs, Ark.; University of Louisville (Ky.) Medical Department, 1889; died May 16, aged 94.

Gunn, Aubrey Jackson Ⓜ Versailles, Mo.; Barnes Medical College, St. Louis, 1904; died May 8, aged 78.

Hall, Ralph Marsh Ⓜ Cold Spring, N. Y.; Albany (N. Y.) Medical College, 1915; veteran of World War I; associated with the Julia L. Butterfield Memorial Hospital, where he was a trustee; died May 21, aged 67.

Heard, E. Felton, Goree, Texas; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1902; died in Dallas May 12, aged 81.

Hemler, William Francis, Tampa, Fla.; Georgetown University School of Medicine, Washington, D. C., 1904; at one time on the faculty at his alma mater and the Georgetown Hospital in Washington, D. C.; died May 11, aged 80.

Ingber, Irving Samuel Ⓜ San Francisco; Long Island College Hospital, Brooklyn, 1913; specialist certified by the American Board of Radiology; member of the American Roentgen Ray Society, Radiological Society of North America, and the American College of Radiology; veteran of World War I; head of the radiology department, Mary's Help Hospital; died in the Mills Memorial Hospital in San Mateo, May 18, aged 70.

Jaques, Jefferson Singleton, St. Louis; University of West Tennessee College of Medicine and Surgery, Memphis, Tenn., 1915; died in the Koch Hospital May 17, aged 73.

Jernstrom, Roy E. Ⓜ Rapid City, S. D.; born in Escanaba, Mich., Sept. 23, 1896; University of Minnesota Medical School, Minneapolis, 1923; past-president of the South Dakota State Medical Association; Black Hills District Medical Society and Rapid City Medical Society; member of the American Fracture Association; fellow of the International College of Surgeons and the American College of Surgeons; served as president of the school board of Rapid City; veteran of World War I; medical member of the Selective Service Board from 1941 to 1945; associated with the Bennett-Clarkson Memorial and St. John's McNamara hospitals; died in Rochester, Minn., May 11, aged 62.

Keeney, Cadwell Benson Ⓜ Summit, N. J.; Columbia University College of Physicians and Surgeons, New York City, 1907; veteran of World War I; on the Selective Service Board during World War II; past-president of the city board of health; for many years on the staff of the Overlook Hospital; received the Golden Merit Award of the Medical Society of New Jersey for half a century of service; died May 22, aged 77.

Keil, Charles A., New York City; Fordham University School of Medicine, New York City, 1918; member of the Industrial Medical Association; died May 19, aged 68.

Keller, Jacob Adlai, Chesterfield, Mass.; Columbia University College of Physicians and Surgeons, New York City, 1905; member of the board of health and served as school physician; associated with the Cooley Dickinson Hospital in Northampton, where he died May 11, aged 79.

Lanier, Louis Fielding Ⓜ Sylvania, Ga.; Medical College of Georgia, Augusta, 1910; associated with the Screven County Hospital, where he died May 11, aged 81.

Lee, John Gordon Ⓜ Washington, D. C.; born in Edmonton, Alta., Canada, June 7, 1902; McGill University Faculty of Medicine, Montreal, Que., Canada, 1928; member of the American Association for the Surgery of Trauma; fellow of the American College of Surgeons; specialist certified by the American Board of Surgery; veteran of World War II; clinical adjunct professor of surgery at Georgetown University School of Medicine and adjunct clinical professor of surgery at George Washington University School of Medicine; interned at the Royal Victoria Hospital in Montreal, Que., Canada, and the Presbyterian Hospital in New York City; served a residency at the Lakeside Hospital in Cleveland, Bellevue Hospital in New York City and the Free Hospital for Women in Brookline, Mass.; chief of surgical service, Veterans Administration Hospital (Mount Alto); died at his home in Silver Spring, Md., May 9, aged 56.

Leopold, Albert Reid Ⓜ Lewistown, Pa.; University of Pittsburgh School of Medicine, 1927; served as secretary and president of the Mifflin-Juniata Counties Medical Society; for many years member and chairman of the board of health; associated with the Lewistown Hospital; died in the Presbyterian Hospital, Pittsburgh, May 9, aged 57.

Little, Albion Henry, Portland, Maine; Medical School of Maine, Portland, 1899; served in France during World War I; past-president of the Cumberland County Medical Society; associated with the Maine Eye and Ear Infirmary; died in Yarmouth May 16, aged 82.

Lo Vene, Arthur Wilhelm, Galesburg, Ill.; Illinois Medical College, Chicago, 1908; associated with the Mercy Hospital in Burlington, Iowa; died in Peoria April 14, aged 76.

Magrish, Philip Ⓜ San Antonio, Texas; University of Cincinnati College of Medicine, 1934; specialist certified by the American Board of Pediatrics; fellow of the American Academy of Pediatrics; past-president of the San Antonio Pediatric Society; veteran of World War II; associated with Santa Rosa Hospital, Baptist Memorial Hospital, and Nix Memorial Hospital; died May 11, aged 50.

Maxson, Frank Theodore Ⓜ Seattle; University of Pennsylvania Department of Medicine, Philadelphia, 1902; veteran of World Wars I and II; for many years associated with the city fire department and in 1957 was honored by the city council for his service; past-president of the King County Medical Society; member of the Association of Military Surgeons of the United States; on the staffs of the

Providence, Doctors, Swedish, and Seattle General hospitals; died in the Veterans Administration Hospital May 20, aged 79.

McClements, William Montgomery Ⓜ Pittsburgh; Jefferson Medical College of Philadelphia, 1935; veteran of World War II; on the staff of the Magee Hospital; died May 17, aged 52.

McKinley, Arthur O., Salisbury, Pa.; College of Physicians and Surgeons, Baltimore, 1894; died in the Meyersdale (Pa.) Community Hospital May 4, aged 91.

McLean, Sterling Alexander Ⓜ Middleboro, Mass.; McGill University Faculty of Medicine, Montreal, Que., Canada, 1934; medical examiner of the Fourth District, Plymouth County; veteran of World War II; secretary of the staff of St. Luke's Hospital; died May 16, aged 50.

Milburn, Azby Alexander Ⓜ Weston, W. Va.; Medical College of Virginia, Richmond, 1927; member of the American Psychiatric Association; associated with the Weston State Hospital; died May 18, aged 59.

Miller, Clay O. Ⓜ Chicago; University of Illinois College of Medicine, Chicago, 1926; served on the faculty of Stritch School of Medicine of Loyola University; veteran of World Wars I and II; specialist certified by the American Board of Urology; member of the American Urological Association; fellow of the International College of Surgeons and the American College of Surgeons; on the staff of Henrotin Hospital; consultant, Veterans Administration Hospital, Hines, Ill.; chairman of the department of urology at West Suburban Hospital in Oak Park, where he died May 24, aged 61.

Moore, Harry Beaumont, Portland, Ore.; Jefferson Medical College of Philadelphia, 1913; died May 19, aged 71.

Muttart, George Wheelock Ⓜ Jersey City, N. J.; University of the City of New York Medical Department, New York City, 1892; served on the staffs of the Christ, Fairmount, and Greenville hospitals; died in New York City May 16, aged 92.

Newbill, James Ⓜ Little Rock, Ark.; University of Arkansas School of Medicine, Little Rock, 1941; member of the American Society of Anesthesiologists; past-president of the Arkansas Society of Anesthesiology; veteran of World War II; on the staff of the Arkansas Baptist Hospital; died May 10, aged 45.

Paganelli, Joseph Erpinio Ⓜ Staten Island, N. Y.; Long Island College Hospital, Brooklyn, 1917; veteran of World Wars I and II; served on the staffs of the New York Eye and Ear Infirmary and the Veterans Administration Hospital in New York City; associated with St. Vincent's and Staten Island hospitals; associate attending physician at the Richmond Memorial Hospital, where he died May 23, aged 68.

Pellens, Mildred, Bridgeport, Conn.; Cornell University Medical College, New York City, 1930; member of the American Psychiatric Association; served on the staff of the Bridgeport Hospital, where she died May 1, aged 62.

Richards, Lloyd Hildrique, Phoenix, Ariz.; St. Louis College of Physicians and Surgeons, 1901; formerly associated with the Indian Service; died May 5, aged 83.

Rosenbaum, Louis Ⓜ New York City; George Washington University School of Medicine, Washington, D. C., 1927; fellow of the American College of Chest Physicians; formerly on the faculty of Columbia University College of Physicians and Surgeons; veteran of World War II; examining physician for the department of health and chief of consultation chest service at the Harlem Health Center; on the staffs of the Harlem, Lincoln, and Riverside hospitals; died in the Mount Sinai Hospital May 16, aged 57.

Ross, William Edson Ⓜ Jacksonville, Fla.; University of Vermont College of Medicine, Burlington, 1904; past-president of the Florida Medical Association; served on the staff of St. Luke's Hospital; died May 16, aged 80.

Shepler, Robert MacMurran Ⓜ Carlisle, Pa.; Jefferson Medical College of Philadelphia, 1902; fellow of the International College of Surgeons and the American College of Surgeons; past-president of the board of health of Carlisle; associated with the Carlisle Hospital; died May 12, aged 85.

Spahr, Mary Burchard Ⓜ Ithaca, N. Y.; Cornell University Medical College, New York City, 1922; specialist certified by the American Board of Pediatrics; member of the American Academy of Pediatrics; on the staff of the Tompkins County Memorial Hospital; died May 25, aged 62.

Spurney, Paul Marcus Ⓜ Cleveland; Western Reserve University School of Medicine, Cleveland, 1917; veteran of World War I; for many years health officer of Shaker Heights; fellow of the International College of Surgeons; for many years chief of staff of the Polyclinic Hospital; died in the Lakeside Hospital April 25, aged 66.

Stites, Thomas Henry Atherton Ⓜ Nazareth, Pa.; born in Wyoming, Pa., April 26, 1875; University of Pennsylvania Department of Medicine, Philadelphia, 1901; veteran of the Spanish–American War; fellow of the American College of Physicians; member of the American Trudeau Society; served as president, vice-president, and secretary of the Northampton County Medical Society; at one time associated with the Pensylvania State Health Department as medical inspector of dispensaries; served with the U. S. Public Health Service Reserve, on the staff of the U. S. Public Health Service Hospital No. 26 in Greenville, S. C., on the staff of the U. S. Public Health Service Hospital No. 27 in Alexandria, La., medical director of the Pennsylvania State Sanatorium for Tuberculosis No. 2 in Cresson, Pennsylvania State Sanatorium for Tuberculosis No. 3 in Hamburg, and attending physician at the West Mountain Hospital in Scranton; formerly vice-president of the First National Bank and past-president of the Rotary Club in Cresson, Pa.; past-president of the Nazareth Rotary Club; for many years editor of the Bulletin of the *Northampton County Medical Society;* died May 23, aged 84.

Storkan, Joseph Charles Ⓜ Gardena, Calif.; Creighton University School of Medicine, Omaha, 1914; veteran of World War I; served as mayor of Plentywood; associated with the Las Campanas Hospital, Compton, where he was past-president of the medical staff; died in St. Mary's Hospital, Long Beach, May 12, aged 72.

Tirrell, John Mahlon, Minneapolis, Minn.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1900; died in the Doctors Memorial Hospital April 26, aged 83.

Townsend, Arthur Melvin Sr., Nashville, Tenn.; Meharry Medical College, Nashville, 1902; served on the faculty of his alma mater; died April 20, aged 83.

Tucker, Edmond D. Ⓜ Nutter Fort, W. Va.; College of Physicians and Surgeons, Baltimore, 1907; member of the staff of St. Mary's Hospital in Clarksburg; died May 17, aged 79.

Vocale, Antonio, Chicago; Regia Università degli Studi di Pavia. Facoltà di Medicina e Chirurgia, Italy, 1940; interned at Mother Cabrini Memorial Hospital; died in April, aged 50.

Voris, Henry McMunn Ⓜ Stuart, Fla.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1903; for many years practiced in East St. Louis, Ill.; veteran of World War I; died April 26, aged 80.

Wagner, George Garfield Jr. Ⓜ Gowanda, N. Y.; *University of Buffalo School of Medicine, 1929;* member of the American College of Chest Physicians and the American Trudeau Society; served on the staff of the J. N. Adam Memorial Hospital in Perrysburg; died April 16, aged 53.

Wiley, George Adrian Ⓜ Norman, Okla.; Northwestern University Medical School, Chicago, 1933; specialist certified by the American Board of Ophthalmology; member of the American Academy of Ophthalmology and Otolaryngology and the Association for Research in Ophthalmology; assistant professor of ophthalmology at the University of Oklahoma School of Medicine in Oklahoma City; associated with University Hospitals in Oklahoma City and the Norman Municipal Hospital; died April 27, aged 54.

Wolf, Heinrich Franz Ⓜ New York City; born in Bistrau, Austria, Sept. 23, 1872; Deutsche Universität Medizinische Fakultät, Prague, Austria, 1897; specialist certified by the American Board of Physical Medicine and Rehabilitation; instructor in physical medicine at Columbia University College of Physicians and Surgeons from 1910 to 1932; member and past-president of the New York Society of Physical Medicine; member of the American Association for the Advancement of Science; fellow of the New York Academy of Medicine and the American Congress of Physical Medicine; co-founder and director of the Eastern School for Physicians' Aides; consultant at the Mount Sinai Hospital, where in 1910 he was appointed chief of the department of physical medicine, a position he held until 1932; from 1932 to 1938 attendant director of physical medicine at the Central Neurological Hospital; author of "A Textbook of Physical Therapy," "Shortwave and General Electrotherapy," "The Practice of Physical Medicine," and "Philosophy for the Common Man"; died while vacationing in Seville, Spain, May 12, aged 86.

Wolfer, Henry Ⓜ Monterey, Mass.; University and Bellevue Hospital Medical College, New York City, 1908; specialist certified by the American Board of Internal Medicine; fellow of the American *College of Physicians; from 1942 to 1944* clinical professor of medicine at the Long Island College of Medicine in Brooklyn, where he was at one time instructor and assistant clinical professor of medicine; formerly associated with the Cumberland Hospital in Brooklyn; served as consulting physician at the Kings County Hospital and the Long Island College Hospital in Brooklyn; died May 23, aged 73.

Wronker, Benno M., New York City; Columbia University College of Physicians and Surgeons, New York City, 1909; died May 26, aged 73.

Yamada, So Sabro, Los Angeles; Stanford University School of Medicine, San Francisco, 1922; member of the American Trudeau Society; died in the Japanese Hospital Feb. 27, aged 68.

Zaff, Fred Ⓜ New Haven, Conn.; University of Michigan Medical School, Ann Arbor, 1937; assistant clinical professor of radiology at Yale University School of Medicine; specialist certified by the American Board of Radiology; veteran of World War II; member of the American College of Radiology; associated with the Veterans Administration Hospital in West Haven; radiologist at the Grace-New Haven Community Hospital, where he died March 12, aged 47.

FOREIGN LETTERS

AUSTRIA

Congenital Dislocation of the Hip.—At the meeting of the Austrian Pediatric Society in Vienna in April Dr. P. Erlacher reported that the classic method of treatment for congenital dislocation of the hip, as devised by Lorenz in 1895, has undergone various modifications. Lorenz recommended that repositioning not be attempted before the 2nd year of life, but it has been recognized that this procedure can be accomplished more easily when the child is younger. It is, therefore, important to diagnose the dislocation as early as possible. With the help of roentgenograms the diagnosis can be established even in the nursing infant, and in these patients a cure is possible by simple means. One of the earliest signs is "snapping" of the joint. Treatment in infancy can be accomplished without anesthesia and without a plaster cast.

In Czechoslovakia, where the incidence of dysplasia and dislocation of the hip is higher than in Austria, pregnant women are cautioned against the dangers of dysplasia in their expected infants. They are informed that by broad swaddling and by the application of the abduction cushion or abduction linen described by Frejka a mild degree of dysplasia may be cured and dislocation thus prevented. As a rule roentgenograms of all infants are obtained at the age of 3 months. The roentgenograms are read by an experienced orthopedist, and infants with abnormal findings are treated.

The speaker considered routine roentgenography necessary only in suspected cases. In the course of this development forceful passive reduction and fixation in a plaster cast have gone out of use in Czechoslovakia. A. Pavlik has achieved spontaneous reduction without the use of force not only in the preliminary stages of dislocation and partial dislocation but also in those with definite dislocation, with the aid of strap-reins. He left it to the child's natural impulse to movement to accomplish spontaneous reduction without external force. The strap-reins extend along the legs to the heel and as suspenders over the shoulders. They are adjusted in a somewhat rectangular positioning of the legs. Otherwise all movements are unrestricted. Frequently with this treatment the tension in the abductors is relieved within a few days, abduction becomes free, and the dislocation suddenly disappears. Pavlik has used this method for mild cases since 1945, and since 1951 also for fully developed dislocations. For best results this method should be used between the 8th and 9th weeks of life, but it may be successful at any time in the 1st year. Of 1,795 dislocations treated by this method spontaneous reduction was obtained in 1,664 or 92.7%. If one adds the patients in preliminary stages and those with partial dislocation, 4,674 hips were treated by this method. The speaker stressed the fact that rebuilding of the head of the femur has not yet been observed. The strap-reins do not interfere with the treatment of intercurrent diseases. This method was used at the orthopedic hospital in Vienna for the last year and Pavlik's experiences with the method were confirmed in 70 patients. Particularly impressive was the case of a 6-month-old girl with arthrogryposis, congenital rigidity of limbs, club hand, and talipes. Such patients are considered particularly hard to treat and some physicians refuse even to attempt to treat the dislocation. Spontaneous reduction was achieved within six weeks in this infant with the aid of the strap-rein.

Broad swaddling is recommended for the prevention of any kind of dysplasia. Infants should not be swaddled upward, with the thighs together, but their thighs should be placed as much as possible in abduction and swaddling cloth, longitudinally folded, led from the back over the buttocks to the abdomen and fixed with a second swaddling cloth or a swaddling ribbon. Over this the straddle-pouch is placed. For the treatment of preliminary stages, partial dislocation, and every dislocation, with or without "snapping," Pavlik's strap-reins are used to achieve spontaneous reduction. The straps are placed on the naked legs extending to the heels and are securely fixed to the suspenders, which are crossed over the back and are worn over the shirt like those used for leather shorts. This is done with hips and knees placed at an angle of more than 90 degrees. After a few days the straps can be removed when the infant is bathed. It is advisable to mark the position of the foot portions of the strap carefully. After reduction has been accomplished the strap-reins should be worn for at least as long as a plaster cast would have been worn with the old treatment. Although the method is simple, roentgenographic follow-up is still necessary. Redislocation was observed in six children, but in two this was due to faulty technique. All children who by the age of 3 months have not obtained a cure should be referred to an orthopedist.

The items in these letters are contributed by regular correspondents in the various foreign countries.

BRAZIL

Gastroscopy.—Pontes and Meirelles reviewed a series of 400 gastroscopies in 346 patients (*Rev. paulista med.* 54:15, 1959). Comparing the gastroscopic with the radiologic and surgical findings, the authors classified these patients as those in whom (1) gastroscopy confirmed the clinical and radiologic diagnosis (102 patients); (2) gastroscopy confirmed a tentative clinical and radiologic diagnosis (29); (3) gastroscopy revealed a lesion in addition to that diagnosed radiologically (18); (4) the correct diagnosis was established by gastroscopy alone (99); (5) gastroscopy invalidated an earlier radiologic diagnosis and established a correct one, later confirmed by operation or new radiologic examination (43); (6) gastroscopy did not contribute to the diagnosis and in some cases even confused the clinical reasoning, since it aroused an erroneous diagnostic suspicion (17); (7) gastroscopy led to an erroneous diagnosis (12); (8) gastroscopy was inconclusive because some food remained in the stomach (13); (9) the diseased areas could not be observed because they were situated in so-called blind spots (6); and (10) the gastroscope could not be introduced into the stomach (7). Thus of the 346 patients examined gastroscopy was of diagnostic aid in 291 or 84.1% (the patients in the first 5 categories). Gastroscopy was of particular value in the diagnosis of certain forms of gastritis. It was also of help in the differential diagnosis of peptic ulcer or cancer.

Laryngoscopy of the Subglottis.—In the examination of the larynx, the subglottic region is always left unexplored, as the vision in this field is restricted, if not impossible. Dr. F. Freire, of the São Paulo State University Hospital, devised a technique for examining this region by retrograde laryngoscopy which he reported to the Associação Paulista de Medicina. With use of six anatomic preparations the examination was begun by puncturing the trachea through the linea alba of the neck, the apparatus being introduced through the laryngotracheal ligament, between the cricoid cartilage and the first tracheal ring. When loss of resistance occurred, meaning that the instrument had entered the tracheal lumen, the mandril was pulled out and an antrorhinopharyngoscope was introduced until the tracheal mucosa was visible.

By inclining the external part of the instrument the lenses and the light were pointed craniad, showing all the subglottis. By pushing the apparatus toward the subglottic dome it was possible to see the anterior and the posterior commissures, the lower surfaces of the vocal cords, and the vocal apophyses of the arytenoid cartilages. Pushing further through the glottis, it was possible to see the lower surface of the ventricular bands corresponding to the interligamentous glottis, part of the ventriculus laryngis, and the foot of the epiglottis. In all six preparations the aspects were the same. Thus, having proof of the feasibility of the procedure, Dr. Freire, using the same technique, examined an 81-year-old man who had carcinoma of the hypopharynx and the larynx to determine what parts should be resected. As a consequence of the retrograde examination it was decided not to perform a resection but to apply roentgenotherapy.

Artery Used to Replace Ureter.—J. L. Itiberê and co-workers, of the São Luís Gonzaga Hospital of Jaçanã, São Paulo, encouraged by their results in using arteries preserved in alcohol to replace blood vessels, tried them as replacements for the ureter. They reported their results to the Associação Paulista de Medicina. Aortas of dogs, preserved in 48% alcohol for 22 to 215 days at room temperature, were used as replacements for the right ureter in 13 dogs. The ureter was severed about 4 cm. from the pelvis of the kidney, its distal stump being tied with cotton thread. The proximal stump was introduced into the arterial lumen, the ureter being maintained in its new position by the fixation of the upper end of the preserved artery to the retroperitoneal fat and the adjacent peritoneum, which was folded over the prosthesis, thus filling the space resulting from the difference in diameter between the artery and the ureter. The prosthesis was then peritonized. Soon after the operation the dogs received 400,000 units of penicillin intramuscularly. In four dogs a left nephrectomy was performed before the grafting in order to ascertain the value of the prosthesis, and postoperative excretory urography was performed in eight. Five dogs died 3, 4, 6, 15, and 150 days after operation, all but one from causes attributable to the operation. Eight dogs were alive 33 to 164 days after the operation, and of these three had previously had a nephrectomy.

DENMARK

BCG Vaccination of School Children.—A law passed in 1946 provided for the annual medical examination for tuberculosis not only of every school child but also of every teacher and the school staff in general. Dr. K. Bojlen (*Ugeskrift for laeger,* April 2, 1959) reported that the percentage of positive tuberculin reactors at the school-entry age in Copenhagen from 1937 to 1957 fell from 17.4 to 3.9. Encouraging as these figures are, they show that during the first seven years of life a child may still become infected. Between 1944 and 1957 50 members of the school staff were found to have active pulmonary tuberculosis. The author's proposed remedy for this state of affairs is a more systematic program of BCG vaccination as early as possible in the scholastic curriculum. Once children are thus vaccinated before entering school it should be possible to follow them closely in this respect throughout their scholastic careers. The author recommended that the routine practice of giving newborn infants in maternity hospitals BCG vaccination be revived. This was done in one such hospital in 1950, and may have contributed to the fall in the percentage of positive tuberculin reactors in 1957.

Poliomyelitis Vaccination.—The State Serum Institute in Copenhagen issued a memorandum on poliomyelitis vaccination. A series of four injections will be given free of charge to anyone under 18 years of age. As paralytic cases have occurred in quite young children, the lowest age limit has been brought still further down, and the vaccine can now be given to children aged only 4 or 5 months, but as infants are poor antibody-makers, because their mothers have transmitted antibodies to them, it is well to reduce the interval between each injection to one month. After the age of 1 year the interval between the first and second injection should be four to six weeks, between the second and the third injection from 9 to 12 months, and between the third and fourth injection about one year. When in doubt about spacing of doses it is better to overdo than to underdo vaccination. The poliomyelitis vaccine and the diphtheria-tetanus toxoid can be given on the same day.

Stillbirth Rates.—Prof. D. Baird of the University of Aberdeen spoke on stillbirths at a meeting of the Danish Gynecological and Obstetric Society (*Ugeskrift for laeger*, April 9, 1959). He stated that in 1956 Denmark had a stillbirth rate of 17 per 1,000 births, whereas the corresponding rate for England and Wales was 23. The figures for Scotland also point to the relative superiority enjoyed in this respect by Denmark. The stillbirth rate appears to be correlated with the cesarean section rate, as in Denmark it is about one-third of that for England. The reason why the Danes have achieved better results with simpler means, with regard to stillbirths, than the English and the Scottish may, in Baird's opinion, be found in the better average physique of Danes. The mean height of Danish women is much greater than that of their Scottish sisters. This may be because of the agricultural life led by the Danes, who have been spared the slums created by an industrial mode of life.

Cancer Propaganda and Tobacco Smoking.—In the *Danish Medical Bulletin* for March, 1959 (vol. 6), Dr. A. Nörgaard traced the influence of fear of cancer on the consumption of tobacco. Toward the end of 1953 the Danish newspapers carried on an exhaustive debate on the alleged effects of cigarette smoking on the lungs, with special reference to cancer. To measure the reaction to this debate questions were addressed during the first four months of 1954 to 4,260 male and 2,089 female smokers. The answers showed that only 158 (3.7%) men and 90 (4.3%) women had stopped smoking altogether. These figures can, however, be made to look more impressive by applying them to the whole of Denmark, with the calculation that had this census been conducted on a national scale about 46,000 men and 28,000 women would have changed their smoking habits and 5,800 men and 3,200 women would have ceased to smoke altogether in response to the debate.

Arterial Transplants.—Dr. P. A. Gammelgaard and co-workers (*Ugeskrift for laeger*, March 19, 1959) stated that in the sterilization of dry-frozen blood vessels in the artery bank ethylene oxide has been replaced, because of its explosive properties and irritant effect on mucosa, by a penicillin-streptomycin mixture. Bacteriological and histological tests were made directly after excision, after sterilization, and after dry-freezing. Although the supply to the artery bank was taken from persons under the age of 40 years whose deaths had occurred less than 48 hours earlier, the samples discarded on account of such degenerative changes as atherosclerosis amounted to 35%. On a follow-up examination six months to two years after operation 13 of 17 patients who had by-pass transplantations had satisfactory results, whereas thromboses had occurred in the others. In view of the legal difficulties arising from the employment of human graft material the search for artificial substitutes has been intensified. Ivalon has been shown to undergo certain structural changes and to become too stiff in the human body. Crimped Teflon promises to be a satisfactory successor by virtue of the facility with which it can be handled and the retention of its best qualities in the human body, in which it is biologically inert.

FINLAND

Relapses After Surgery for Pulmonary Tuberculosis.—O. Peräsalo and co-workers (*Ann. chir. et gynaec. Fenniae* 48:1-18, 1959) made a follow-up study of a series of 527 tuberculous patients who were treated surgically between 1949 and 1957. Statistics on the 273 subjected to thoracoplasty showed that after an observation period of one and one-half to eight years primary and secondary cures were obtained in 71.2%, and 15.9% were still ill. Primary surgical mortality accounted for 2.5% and late tuberculous complications proved fatal in 8.6%. The data on 96 patients subjected to pneumolysis showed that, with an observation period varying from two and one-half to eight years, the percentage of primary and secondary cures was 83.4 and 12% were still ill. Primary surgical mortality was 2.1% and mortality from late tuberculous complications was 2.5%. The follow-up studies on 153 patients operated on by pulmonary resection showed that, after an observation period of six months to six years, the proportion of cures was 90.2% and 3.3% were still ill. Primary surgical mortality was 3.9%, and the mortality from late tuberculous complications was 2.6%. The relapse rate in patients with extensive cavitation was 55.3% after thoracoplasty and 46.7% after pneumolysis. Most of these relapses, however, occurred after the thoracoplasties and pneumolyses performed between 1949 and 1952, when the new drugs were not yet routinely used. In analyzing the type of resection used no major differences were apparent between the groups of those who had lobectomy, lobectomy plus segmental resection, and segmental resection alone. Their relapse rates were 13.4 to 11.4%. There were no relapses after pneumonectomy or polysegmental resection.

Surgery in Aged Persons.—Viikari and Vaalasti (*Ann. chir. et gynaec. Fenniae* 48:19-30, 1959) reviewed a series of 565 operations performed on persons over 70 years of age. Of these 72 were over 80 years of age. The total postoperative mortality was 11%, 9% for those under and 22% for those over 80. The mortality after emergency operations was 21%, that after operations with absolute indications 15%, and that after elective operations 5%. The chief causes of postoperative death were embolism, cardiac failure, and pneumonia. The author stressed the need for appropriate preoperative management of patients in order to diminish postoperative complications. In patients in whom a curative measure was in question, such as those with enlarged prostate, severe pains caused by biliary calculi, and hernia, the decision was usually easily made, for modern anesthesia increases the chances of a favorable outcome. The situation is more difficult if a malignant tumor is involved and a radical operation is necessary. The life of a person aged 70 to 80 may not be agreeable if, for example, the whole stomach or a lung is removed, however successfully. The life of such a patient would not be appreciably lengthened and as a result of the operation his last years might be much more difficult than they would be if the operation had not been performed.

GERMANY

Hypergammaglobulinemia.—Kühn and Hanusch reported, at the 65th meeting of the German Society of internal medicine at Wiesbaden in April, that 55% of 3,000 paper electrophoreses showed an increase of the gamma globulin fraction of more than 40%. Most of these were from patients with severe subacute and chronic hepatitis, cholangitis, hepatic cirrhosis, tumors (chiefly leukemia), and inflammatory diseases of the heart, lungs, and pleura. The gamma globulin deflection showed, with few exceptions, a broad base, and, especially in hepatic diseases, was asymmetric. In seven patients the gamma globulins were arranged in a more or less sharply pointed fraction with a narrow base; only one of these was a true gamma plasmocytoma. Patients with acute inflammatory and neoplastic diseases usually showed an increase of serum protein–bound carbohydrates in the rapidly moving range, while those with chronic inflammatory diseases, especially of the liver, also showed a large portion of serum protein–bound carbohydrates in the range of the increased gamma globulin fraction.

Antirheumatic Drugs and Hyaluronidase.—At the same meeting H. Mathies of Munich stated that previous studies had shown that the hyaluronidase-inhibiting effect of antirheumatic drugs was bound to the function of the adrenal medulla (release of catecholamine). An activity of the adrenal cortex can be proved, but it does not play a role in the process of hyaluronidase inhibition. Release of catecholamine from the adrenal medulla was indirectly proved by determination of the catecholamine content of the adrenals after administration of various antirheumatic drugs and treatments. Intensive studies showed that antirheumatic agents are of two classes. One kind (salicylates and glucocorticoids) affect the release of catecholamine mainly at the expense of the normal adrenal depots; the other (phenylbutazone and estrogens) give rise to an increase in the production of catecholamine, and a surplus of this is then released.

The inhibition of hyaluronidase does not take place during the primary period of effect of catecholamine but only after its subsidence. Intensive work on the dependence of hyaluronidase inhibition on the catecholamine effect has already been done. It depends not on the time of catecholamine release but on the time of decline of the previously elevated catecholamine level. These findings suggested that the release of catecholamine starts a reactional process that requires further clarification. From the spreading effect achieved with a dyestuff plus hyaluronidase applied to rats and human beings it was seen that protamine sulfate blocks the hyaluronidase-inhibiting effect of heparin and all other antirheumatic substances possessing this property. The inhibition of hyaluronidase by epinephrine, levarterenol, histamine, and all other hyaluronidase-inhibiting substances and treatments (salicylates, phenylbutazone, adrenocortical hormones, chlorethylbenzmethoxazone, mud baths, and sulfur baths) is blocked by ergotamine tartrate and by antihistaminics. Not only ergotamine tartrate but also ganglionic blockers block the inhibition of hyaluronidase.

Polysaccharide Content of Fibrin.—At the same meeting J. Rechenberger of Leipzig reported that carbohydrates are present as integral parts in the serum protein bodies under both physiological and pathological conditions. This polysaccharide portion increases in most pathological conditions. Only in diseases of the liver parenchyma were the levels found to keep within the normal range or to be only slightly elevated. A certain polysaccharide portion is also always found in fibrin. Fibrin was prepared from oxalate plasma by means of thrombin. With the orcin reaction and a modified Elson-Morgan test it was possible to demonstrate in various conditions that the polysaccharides hexosen and hexosamine were present in varied amounts, depending on the underlying disease. High polysaccharide levels were associated with tumors, especially bronchial carcinoma, and in such inflammatory diseases of the lung as lobar pneumonia. In diabetes, especially if attended by complications, the polysaccharide portion was increased, markedly in some patients, parallel to the increase of fibrin nitrogen. Investigations further suggested that carbohydrates were closely linked with the synthesis and perhaps also the function of the fiber material.

Hepatitis Contagiosa Canis.—At the same meeting Mohr and Schindler of Hamburg stated that viral hepatitis in a dog (hepatitis contagiosa canis) was first described by Rubarth in 1947. The causative organism is identical with that of fox encephalitis, discovered by Green in foxes in 1925. In 1933 Green experimentally investigated the pathogenicity of this virus for dogs. While in the fox the infection takes the course of an encephalitis, in the dog it is characterized by hepatitis. The report that ferrets and rabbits are susceptible to this virus has not been proved. Recent reports, however, indicated a possibility of transmission to monkeys, which suggested that human beings might become infected.

The observation of an attack in a veterinarian caused the authors to investigate whether the virus of hepatitis contagiosa canis might be pathogenic for man. Two more human cases were observed in the veterinarian's environment, and these also showed more or less marked symptoms and a high serologic titer for this infection. Liver swelling was the most characteristic symptom. Liver biopsy performed in another clinic, regrettably only toward the final stage of the disease, revealed histological indications of a noncharacteristic irritation of the liver tissue, with swellings of Kupffer's cells and an increase mainly of eosinophils in the lobular sinusoids. Liver function tests also showed slight deviations. From then on, one of the authors investigated serums of patients with hepatitis in the clinic and also serums from patients suspected of having psittacosis, toxoplasmosis, or undefined viral infection.

The serums were examined for hepatitis contagiosa antibodies by the complement-fixation reaction. Two positive reactions were obtained. In one it was too weak to permit any evaluation, but in the second a marked titer deviation was observed. The latter was in a serum that had been sent for diagnosis because of undefined viral infection. This patient had had contact with cats and dogs. On the first day of the disease an itching rash had been observed that spread over the whole body on the second day. The patient's temperature was subfebrile. He had conjunctivitis, bronchitis, and swellings of the cervical, buccal, axillary, and inguinal lymph nodes. The leukocyte count was 2,300 with an increase of plasma cells and monocytes. The sedimentation rate was increased. A follow-up examination after four months confirmed subsidence of all symptoms, and at that time the result of the serologic test had become negative. The report pointed out that people in close contact with dogs may acquire this viral infection. It may run a mild course with only minor involvement of the liver, or it may develop as a severe disease with hepatic involvment.

Absorption of Orally Taken Penicillin.—A. Lange and co-workers (*Arzneimittel-Forschung*, vol. 9, 1959) determined the blood levels of healthy volunteers after oral administration of 100,000 and 200,000 units of phenoxymethyl penicillin (PV), 100,000 and 200,000 units of potassium phenoxymethyl penicillin (PVK), and a combination of 100,000 units each of PV and PVK. In the PV-treated group receiving 100,000 units (23 subjects) three types of reaction were observed: maximum values occurring after one hour (early-level group, 8 subjects); two hours (middle-level group, 10 subjects); and four hours (late-level group, 5 subjects). With double the dose there was a greater portion of early levels: 11 early, 3 middle, and 2 late levels. In the PVK-treated group receiving 100,000 units (15 subjects) peak levels occurred in 13 subjects after only one hour, because of the more rapid absorption of the potassium penicillin; only 2 subjects had middle levels. All of 15 subjects receiving 200,000 units of PVK had early levels. The values obtained with the combination of 100,000 units of PV and 100,000 units of PVK in 18 subjects were surprising. The ratio of early to late levels was 14:2, but, contrary to expectation, peak levels were higher than after 200,000 units of PV or 200,000 units of PVK. Also the values after four hours were clearly higher than those from 200,000 units of PV. The comparatively great range of values was due to individual differences in decomposition, excretion, and distribution of the orally taken penicillins. Body weight, which also contributes to the divergence of values was not considered in these tests.

Pseudoarthritis After Withdrawal of Prednisone.—Dölle and Martini (*Med. klin.* 53:2177, 1958) reported that steroid pseudoarthritis with fatigue, diffuse muscle and joint pain, and psychic lability is especially likely to develop in women during the menopause after long-term corticosteroid treatment of primary chronic rheumatoid arthritis. The authors observed the same syndrome in three women in the menopause after sudden termination of prednisone treatment for idiopathic liver cirrhosis. Joint pain predominated in the first and polyneuritic symptoms in the two others. Physical therapy and treatment with salicylic acid (of differential diagnostic importance) had no effect. Treatment therefore consisted of gradual reduction of the prednisone dosage until its complete withdrawal. If the pseudorheumatism occurs after termination of the hormone treatment, prednisone should be reinstituted in low and gradually declining doses, until it is finally withdrawn.

Separation of Urinary 17-Ketosteroids.—At the 65th meeting of the German internal medicine society at Wiesbaden in April, Heni and Göbel of Tubingen stated that separation by paper chromatography of the 17-ketosteroids in urine into their components is important in the differential diagnosis of hypercorticoidism. A method was worked out which allows satisfactory but easy separation of androsterone, etiocholanolone, dehydro-epiandrosterone, 11-keto-androsterone, 11-keto-etiocholanolone, 11-hydroxy-androsterone, and 11-hydroxy-etiocholanolone. The method was used in the examination of several forms of adrenocortical hyperfunction. Separate demonstration of metabolites from androgens and cortins (within the 17-ketosteroid fraction) permits more definite conclusions of the type of adrenocortical dysfunction than was possible with the previously used group reactions of the urinary corticoids or with adsorption chromatography to alumina.

In the purely metabolic form of pituitary basophilism only an increase in such metabolites of cortisone as etiocholanolone, 11-keto-etiocholanolone and 11-hydroxy-etiocholanolone is found. In the mixed forms an increase in 11-keto-androsterone and 11-hydroxy-androsterone is also observed. Adrenal hirsutism with elevated 17-ketosteroid values is associated with an increase in dehydro-epiandrosterone, 11-hydroxy-androsterone, and androsterone. The clinical difficulties in the differential diagnosis of uncomplicated hirsuties without elevation of the 17-ketosteroid levels are relieved further by administration of ACTH. In adrenocortical dysfunction, increased excretion of metabolites from androgens is observed. This is absent when the condition is of extra-adrenal origin. Congenital forms of the adrenogenital syndrome, which are characterized by disturbances of the synthesis of steroid hormones, show an increase in 11-hydroxy-androsterone, while the level of dehydroepiandrosterone is only slightly elevated.

Absolute Arrhythmia.—At the same meeting Franke and Stein reported on a series of 900 patients with a critical inflammatory or degenerative myocardial disease, valvular heart disease, or thyrotoxicosis and absolute arrhythmia. Only about 10% of the patients complained of cardiac irregularities. About 50% of those with valvular heart disease and 25% of those with myocardial disease had cardiac decompensation. The most frequent arrhythmia was auricular fibrillation. Pure auricular flutter was observed in only 5%. In 80% of the patients the electrocardiogram (ECG) showed further signs of damage and 23 of 46 patients with paroxysmal absolute arrhythmia had a pathological ECG during the rhythmic phases. The average age of the patients with valvular heart disease was lower than that of the others, and twice as many had a history of embolism. Among the patients with valvular heart disease many had manifest cardiac failure and roentgenographically demonstrable auricular dilatation. Of the 80 patients receiving quinidine regular rhythm was established for lengthy periods in 16.

Secondary Renal Insufficiency.—At the same meeting J. Frey of Freiburg reported that in diabetics increasing glucosuria (up to 150 Gm. per day) was accompanied by a steady increase in urinary volume and sodium, chloride, potassium, and phosphate excretion. The excretion of urea was less affected and creatinine excretion hardly at all. The concentration of urine was only slightly increased and with further sugar excretion returned to aglucosuric values. The speaker further stated that diabetic coma was a special form of functional kidney damage which might be associated with marked chloride and sodium deficiency and other electrolyte changes in the plasma, such as hyperkalemia and hypokalemia. Because of the higher excretion of urates and of morphologic changes of the kidneys resulting in gross deposits of urates in the kidneys in gout, renal function is impaired. The concentrating power of the kidneys is impaired and the excretory power reduced, with the exception of urate clearance which is only slightly altered if at all and during the gouty attack may even be increased. In Fanconi's rachitic syndrome it is difficult to distinguish renal and extrarenal conditions, since this syndrome is not an anatomic but a clinical entity. The associated phosphaturia leads to osteomalacia. The prognosis is better in adults than in children.

INDIA

Tetracycline for Typhoid.—Parikh and Thanawala (*Journal of the Indian Medical Association*, vol. 32, April 16, 1959) gave tetracycline alone and in combination with chloramphenicol to 189 patients with typhoid. Salmonella typhosi in vitro was found to be sensitive to between 0.25 and 31.2 mcg. of tetracycline and in vivo to 10, 30, and 60 mcg. of tetracycline. The patients were treated by five regimens: (1) 30 were given 500 mg. of tetracycline every 4 hours; (2) 29 received 500 mg. of tetracycline every 6 hours; (3) 40 were given both 250 mg. of tetracycline and 250 mg. of chloramphenicol three times a day; (4) 28 were given 750 mg. of chloramphenicol twice a day for three to four days, followed by 750 mg. of tetracycline twice a day; and (5) 3 patients with severe toxemia received 500 mg. of tetracycline intravenously twice daily until their temperatures came down to normal; 2 of these were then given chloramphenicol by mouth and one was given tetracycline by mouth. The control group of 59 patients received 1.5 Gm. of chloramphenicol per day. The dosage in all the test groups was reduced gradually after the temperature touched normal, and therapy was continued for 7 to 10 days. If tetracycline failed to bring the temperature down to normal within 7 or 8 days, chloramphenicol was given.

Treatment was started in most of the patients on the 7th to 13th day of fever. There was no significant difference in mortality in those receiving tetracycline alone or chloramphenicol alone. The most remarkable effect of tetracycline was the clearing up of the toxemia. Most of the patients' conditions became nontoxic within 48 to 72 hours, although their temperatures remained above normal. As the patients improved they became more cooperative, and this helped in maintaining nutrition and in rapid recovery. The general weakness so often complained of in convalescence was also absent in patients treated with tetracycline. Chloramphenicol gave satisfactory results in patients who proved refractory to tetracycline. The results in the group receiving both drugs simultaneously were much better than in the control or any other group. Patients who received tetracycline alone or in combination with chloramphenicol were relieved of toxemia earlier than those who received chloramphenicol first and then tetracycline or chloramphenicol alone. The duration of stay in hospital was less in those receiving combined therapy. Both drugs were well tolerated, there being hardly any side-effects. The two drugs given in combination also helped to reduce the carrier state.

Viruses from Sporadic Cases of Meningitis.—S. Paul and co-workers (*Journal of the Indian Medical Association*, vol. 32, April 16, 1959) studied a sporadic series of 27 patients who had encephalitis, with a view to isolating viruses from the stools. Eight healthy children and seven with febrile illness other than encephalitis or aseptic meningitis were included as controls. Samples of stool, cerebrospinal fluid, and blood were examined. Blood specimens in the convalescent state were collected 14 days after the onset of illness. From healthy children and patients with other febrile illness, only stool specimens were collected. All specimens were subjected to tissue culture, mouse inoculation, neutralization tests, and tests for virus isolation. Fourteen cytopathogens were isolated, 13 from stools and 1 from cerebrospinal fluid. Ten were isolated in cultures from patients with encephalitis, aseptic meningitis, or both and two in those from normal healthy children. No such pathogens were isolated in cultures from the seven with febrile illness other than encephalitis. Cultures from one patient with encephalitis yielded two cytopathogens, one from the stool and the other from the cerebrospinal fluid.

All patients with encephalitis had low-grade pyrexia and 10, 2 of whom had paralysis, showed signs of involvement of the central nervous system. Two developed residual paralysis, one died, and the rest recovered. Five samples of cerebrospinal fluid showed pleocytosis, three showed a moderately low sugar level, two increased protein levels, one decreased chloride levels, and two were normal. Only one showed leukocytosis. Results of mouse inoculation tests showed 4 of the 14 cytopathogens to be pathogenic in mice. Neutralization tests showed that of the 14 strains studied 3 were poliovirus 1, one was poliovirus 2, two were poliovirus 3, two were Coxsackie virus B5, 6 could not be neutralized by any of the poliovirus or Coxsackie virus serums used, and of these 6 only 4 could be neutralized by gamma globulin. None of the tested strains were neutralized by pooled monkey serum. The two poliovirus 1 strains were isolated from patients with paralysis or paresis, and one of these had residual paralysis of the lower limb. Poliovirus 3 and Coxsackie virus B5 came from patients with aseptic meningitis. One of these strains was isolated from the cerebrospinal fluid of the patient whose stool cultures yielded poliovirus 2. None of the Coxsackie virus strains were isolated from healthy children.

JAPAN

Fall-out from Nuclear Tests.—A special committee headed by Dr. Totugi and appointed by the Atomic Energy Commission measured the fall-out of radioactive matter in and around Japan in 1957 and the first half of 1958. The fall-out showed a definite cumulative increase with each successive year. In the localities heaviest hit it is fast approaching a dangerous level. Japan seems to receive a heavy fall-out of radioactive dust from all directions—specifically from Eniwetok in the Pacific, from Nevada in the United States, from Siberia, and even from the North Pole. The tests of rain water for radioactive strontium (Sr^{90}) showed more than 8 $\mu\mu$c. In 1956 1 sq. km. in Tokyo contained 2 μc of Sr^{90}. In 1958 it had increased to 12 μc. In 26 separate areas the water supply contained Sr^{90} in a dangerous concentration. Every test of foods grown on the soil showed a high level of Sr^{90}, the most notable being that found in rice. Fortunately, most of it is removed in the millings of the grain; but these heavily charged millings are fed to the live stock whose dairy products and meats are later eaten. We do not yet know whether the Sr^{90} ingested in food and water ultimately reaches the bones. It is estimated that the amount of Sr^{90} ingested daily is 2.03 $\mu\mu$c by the urban and 5.8 $\mu\mu$c by the rural population. If to the above figures we add those for heavily laden drinking water and the unpolished rice used by some we reach a dangerously high daily dose of 26 $\mu\mu$c.

CORRESPONDENCE

A PHILOSOPHY OF MEDICINE

To the Editor:—The time-honored meaning of the word physician is under close scrutiny. We need an immediate and a long-range philosophy of medicine. The immediate needs must come from within the profession. There must be unity in principles, unity in action, and unity of dedication to the fundamental motivations and principles that facilitated the emergence of medicine as a great science.

The motivation of the physician today will have tremendous impetus on the future of medicine. If our primary motivations are knowledge of disease, understanding of the patient, and treatment of the patient, we shall remain true physicians, humanitarians, and practitioners of the healing art. But when our primary motivation revolves around economics, we are in trouble. The latter motivation is then subject to legislation, controls, third-party intervention, and numerous alien impacts on the patient-physician relationship. The large increase in number of malpractice suits against doctors and hospitals proves that the old-time patient-physician relationship is shattered and that courts must now intervene to settle complaints. The person-to-person relationship between patient and physician becomes broken, and the right of preferred information is in jeopardy. Intervention by a third party breaks the most sacred and cherished privilege of medicine, the right to privacy. Great damage can be inflicted on a patient's ego by legislated method and management of his personal history. The physician management of medical care is changing, and this alone has hurt the valuable proved personal relationship which can exist between patient and doctor.

The American way of life is changing, and we must take cognizance of it in any philosophy. Federal legislation relating to medicine is a reality. State legislation providing medical care is increasing. The politicians, the labor leaders, the industrialists, and the insurance companies are now engaged in the administration of American medicine. These basic inroads into the private practice of medicine have been occurring for many years. It is a myth that bureaucratic medicine is cheaper and better than the private practice of medicine. Someone will pay for the operation of political medicine, and in the end it will be the patient—with his life—and the doctor—with his self-respect.

Our immediate reaction to the changes in medical practice are diversified. The medical profession is divided. There are advocates who wish to cooperate with coercion and who accept and promote various agencies and medical programs without investigation or intelligent critical examination. This encourages governmental legislation, facilitates the creation and centralization of medical bureaucracy, and contributes to the policy that leads to the ultimate socialization of medicine and enslavement of both the patient and doctor.

There are physicians who advocate compromise; they say that change is inevitable and that the needs of the people must be met. At the same time they attempt to preserve the private practice of medicine. They study numerous proposals and advocate various schemes that will impress the people and placate the physicians. They affirm freedom of choice of a physician, freedom in rendering medical judgments, and freedom in the pursuit of medical knowledge. The basic fallacy of compromise is third-party intervention, the application of nonmedical judgments, and costly benefits appropriated to the advocates who pretend to render cheaper medical care. You may be sure that when insurance companies write policies they have profit in mind.

There are physicians who advocate open resistance to change. These rugged individualists, staunch adherents to private enterprise, oppose the encroachment on their personal liberty, judgment, and exercise of duty. Freedom is an American heritage and should be allowed to exist between patient and doctor. But the balance of power, greed, and ignorance are against advocates of individual freedom, who lack support from within their profession, are legislated into piecemeal curtailments, and, as individuals, cannot stop the mounting entanglements and inroads being imposed on medical practice. A united approach, rather than individualistic pronouncements, would be more effective.

Our immediate action is diversified. The cooperators endorse, the compromisers negotiate, and the traditionalists oppose intervention. This divided state of opinion leads to chaos; medicine becomes contaminated, and an era of decline will be inaugurated producing the typical decadent socialist-motivated type of doctor.

The long-range view of future medicine requires substantial agreement on a philosophy of medicine. Without an adequate philosophy, we flounder, we opinionate, we wait, we surrender our gains to the politician, the labor leader, and the medical moron. From within the profession must come a unified concept of medical practice, a united approach of combating destructive influences, and a presentation of a constructive program which will insist as well as prove that physicians are able to manage the health and welfare of American medicine and the American people.

History has demonstrated that the greatest advances in medicine occur when medicine becomes the prerogative of the physician. Medicine belongs to trained physicians, not to politicians, insurance companies, or labor leaders. The medical practice act has possibly solved many problems, and the maintaining of high standards of medical practice is good, but the present trend of cooperation and sanction of ancillary persons dealing with the bodies and minds of sick persons will lead to decadence in the quality of medicine. Too many coexisting organizations and too many unqualified people have become private practitioners in the field of medicine. The unscientific and socialistic approach leads to physician deterioration and patient mortality while the scientific methods leads to beneficial results.

The solution to the problems of medicine will result only from unity, philosophic dedication, research, knowledge, understanding, sensitivity, and motivation. These attributes of a great physician will do much to stem the ever-mounting tides and sanctions of socialized medicine, state medicine, political medicine, third-party medicine, and profiteering medicine. Thus far, for the most part, the various forms of medical practices have been executed voluntarily by physicians. It is an error of judgment and lack of social perspective to cooperate with detrimental programs. A return to fundamental principles of scientific medicine and the practice of basic values is necessary if progressive medicine is to survive. There are many physicians who want to practice good medicine and who object to being sold into slavery for a few pieces of silver.

THE STANDARD NOMENCLATURE AND THE INTERNATIONAL STATISTICAL CLASSIFICATION

To the Editor:—As Chairman of the Advisory Medical Board of the Standard Nomenclature of Diseases and Operations published by the American Medical Association, I am seriously concerned about the adverse effect which a report published in the June, 1959, issue of the *Journal of the American Association of Medical Record Librarians* may have on the future use of the Standard Nomenclature in hospitals.

Ten hospitals maintained dual indexes of diseases and operations in their record rooms, one using the numerical coding system of SNDO and the other, the coding system of the International Statistical Classification of Diseases, Injuries, and Causes of Death. The comparative trial is reported to have revealed that the coding and posting time was less with the ISC than with the SNDO. In using the two indexes to obtain records for study, it is reported that not only more records pertinent to the request but also more nonpertinent records were found in the ISC than in the SNDO indexes. These results could have been predicted, for a system with far fewer disease groupings will obviously take less coding and posting time than a more detailed and refined index. Also, the use of a simpler classification with more inclusive groupings will result in more pertinent and, also, more nonpertinent records being drawn from the files for study. In fact, if the experiment had included a consideration of some uncommon diseases, the use of the simpler system with coarse disease groupings would have resulted in drawing a predominant number of nonpertinent records from the clinical files.

Having participated as a member of the United States Committee on Health and Vital Statistics in the last two decennial revisions of the International List, I am aware that the ISC is intended primarily to facilitate the exchange of information on diseases, injuries, and causes of death for public health and administrative purposes. It was not designed for clinical research. If the ISC were to be expanded and its details multiplied to meet the special needs of clinical research, the relative saving in the coding and posting time, its chief advantage over the SNDO indexes, would be wiped out.

The authors of the report on the comparative study admit that almost all the medical record librarians who participated in the study "tend to prefer the greater specificity of SNDO." The authors assume that "this preference is probably affected by greater familiarity with one system than another," but this assumption is unwarranted for the participating medical record librarians expressed their preference after a full year's experience with ISC.

The authors of the report admit that "The SNDO, constructed by expert physicians, is the official nomenclature accepted in the US. The ISC is a classification system, not a nomenclature. . . . Physicians should not be given the ISC manuals to use as an aid in recording diagnoses since this would tend toward use of poor diagnostic terminology." Yet this is exactly what will happen in many hospitals if they abandon the use of SNDO in their record rooms and substitute the ISC indexes. Physicians will soon tend to forsake the use of SNDO, with resulting deterioration in the accuracy and completeness of diagnostic information.

It has taken more than 30 years to develop SNDO and achieve its employment by physicians in hospitals throughout the United States. During these years, it has taught many thousands of medical students, residents, and attending physicians to use exact and meaningful medical terms. The use of SNDO has simplified the work of record room librarians by enabling them to obtain complete diagnoses from the clinical services, which are ready for accurate filing in the disease and operation register.

The report fails to disclose any advantages of the ISC system of sufficient importance in hospital work to counterbalance the serious clinical and educational loss to American medicine which is bound to follow its introduction in hospital record rooms as replacement for SNDO. I sincerely hope that this will not happen.

MISCELLANY

THIRD-PARTY MEDICINE—PAST, PRESENT, AND FUTURE

Cyril Costello, M.D., St. Louis, Mo.

Medical students have informed me that they hear and read virtually nothing which answers their growing curiosity about third-party practice as they approach their entrance into the private practice of medicine. My views on this subject were sought because I am engaged in the private practice of surgery and have also engaged in the encouragement and planning of third-party medical programs in our community.

The term "third party" appears in the 1955 edition of the American Medical Association's "Guiding Principles for Evaluating Management and Union Centers" which, among several features, quotes chapter 7, section 4, pages 26-27 of The Principles of Medical Ethics of the American Medical Association, December, 1954: "Free choice of physician is defined as that degree of freedom in choosing a physician which can be exercised under usual conditions of employment between patients and physicians. The interjection of a third party who has a valid interest, or who intervenes between the physician and the patient, does not per se cause a contract to be unethical. A third party has a valid interest when, by law or volition, the third party assumes legal responsibility and provides for the cost of medical care and indemnity for occupational disability." This statement, through which the American Medical Association approves as ethical properly conducted contract medicine, is apparently the origin of the expression "third party." While the expression is of recent origin, the practice is as ancient as medicine itself. We must, for the purposes of this dissertation, keep in mind that there is a difference between medical art and medical economics. The former is the collection of techniques and skills employed in the prevention and treatment of diseases. The economics comprehends the usages, conditions, and arrangements under which medical services are available.

Little doubt exists that progress in medicine could not have flourished as it has without the aid of third parties. Every culture, however primitive or advanced, has been confronted with a number of basic needs of its people for food, clothing, shelter, a common defense, a moral code, and a variety of entertainments to escape from the humdrum routine of life. Among the mightiest of these great tasks is the maintenance of the health of the people. The success of this effort depends not only on medical technology but also on the economic arrangements under which the medical arts are dispensed.

Historical Evolution

Third-party medicine was one of the great forward steps in civilization. From the earliest days the king had his personal physician, and the latter attended to the physical needs of the entire court, although he was paid and maintained by the king. Even earlier than that, the first manifestation of the good neighbor was found in the story told by the Lord of the unfortunate man who fell among thieves on the road from Jerusalem to Jericho. The Good Samaritan bandaged up his wounds, took him to the inn, and left money for his care, perhaps the first record of third-party medicine.

In his historical evolution man discovered what he called freedom and he harkened back to the days of Athens and Sparta and began to form republics. Even the legislators and tax collectors derived their position and income from the taxes paid by people whom they served, but whom they never saw or knew. Industry also learned that the most efficient way to transact big business was through corporations, although this device, even as far back as Ancient Greece, had never been used except for such things as the maintenance of universities. In the United States, it was not until after our Civil War that the corporation was applied to big business, and this became the birth of the most serious third-party activity of all times.

Until about 1890, a laborer earned about one dollar a day. A man named Samuel Gompers organized workers on the basis that everyone was entitled to fair compensation for his toil and to some enjoyment in life. He organized labor on a fair and just basis, so that the man who worked conscientiously had the kind of opportunity which was taken advantage of by many of our men who subsequently rose from rags to riches. Nowhere in history have so many received so much through opportunity and returned so much to others in labor as in the United States. In the provision of opportunity and improved working conditions, however, medical care and maintenance of health became significant factors.

Hospitals first came into existence along the battlefields of the Holy Land during the first crusade, provided and maintained by a benevolent third party known as the Knights of St. John, who subsequently became the Knights of the Cross and whose chief later became the first king of Prussia. It was found in our early experience with hospitals in the United States that people coming to them could not pay. Hospitals depended for financing on endowments and charitable contributions which, however, were sporadic; thus hospitals could not maintain themselves.

Development in the United States

Until about 1880, life insurance was looked on as immoral, since many contended that it put a premium on murder. Yet today no head of a family in even the humblest circumstances would think of

Annual Phi Rho Sigma Lecture, St. Louis University Medical School, March 3, 1959.

leaving his family unprotected by life insurance. As insurance theory and practice grew and prevailed, not only for life but for protection against unusual losses by fire, theft, and accident, it became logical that the successes in these operations should be applied to protection against losses by sickness and injury. As society grew more complex it was found that, where a serious sickness arose, a family was set back as much as a year's earnings. Thus it was that the modern third party was introduced into medical care, and there has evolved active insurance company participation, including the nonprofit, "Blue" third-party programs of the medical societies. Doctor and hospital care could not exist as we know them today without the third party.

How active has this third party become in private medical care? During the 1929 depression few hospitals survived financially. Today it is likely that most private hospitals would be in desperate condition were it not for the effect of these third-party contributors. In our own Barnes Hospital (which may be typical of a medical center private hospital), 50% of dollar income is paid by third parties, approximately two-thirds of all patients' income is paid by third parties, and approximately two-thirds of all patients admitted to the hospital are sponsored by third-party contributors (personal communication from Dr. Crawford Vermillon, assistant director, Barnes Hospital). It is difficult to believe that any doctor very actively engaged in any type of private medical care today can honestly disclaim interest and participation in third-party medicine, which has been defined, both by official medical circles and by experience in this and other American communities, as ethical, legal, necessary, and prevalent. This should never be confused with socialized (government) medicine, which it strives, by the very nature of its voluntary aid, to oppose. It has become a popular subject in medicine during the past several years because of the great interest shown by the population in seeking access to modern medical care on a prepaid basis, as well as the increased third-party activity by industrial concerns, labor unions, and insurance companies representing large groups of individuals.

The oldest management third-party program dates back to 1868. The oldest union third-party program dates back to 1913, with approximately 50 such centers in operation today and, as pointed out by Dr. Robert Bassett at his recent installation as president of the St. Louis Medical Society, "Third Parties include: 1) Blue plans sponsored by doctors; 2) Commercial insurance companies; 3) Government agencies which control the Vendor program, Medicare, V. A., and other programs; 4) So-called independent plans; 5) Industrial medicine in all of its phases; 6) The widespread Labor Health plans, all to the extent that today over one hundred and ten million Americans have some protection against illness and accident (Bulletin, St. Louis Medicine, Jan. 14, 1959)."

In St. Louis, third parties of various types have long practiced employment of physicians for various degrees of medical service in behalf of their members. The following well-known and well-established industrial organizations practice third-party medicine: General Electric Company, Union Electric Company, United States Defense Corporation, Anheuser-Busch Company, Fisher Body Company, American Brake Shoe Company, Southwestern Bell Telephone Company, Emerson Electric Company, Mallinckrodt Company, Monsanto Chemical Company, International Shoe Company, Pevely Dairy Company, National Lead Company, General Cable Corporation, Famous Barr Company, McDonald Aircraft Company, Aeronautical Chart & Information Center, Frisco Railway, St. Louis Public Service Company, and numerous others. In addition, groups not to be classified as industrial or business concerns engage in the same type of third-party employment of physicians; and these include both St. Louis University and Washington University with their student health centers and medical schools, which provides employment for teaching and medical practice; family agencies and children's institutions; nursing homes; the St. Louis Society for Crippled Children; the city and county health departments; the city, county, and state hospitals; and others. Still another group performing as a third party in employing physicians in this community is organized labor through such plans as the Labor Health Institute of the Teamsters, the Medical Institute of the Meat Cutters, the Ladies Garment Workers Medical Center, the United Mine Workers program, and the Missouri Pacific Hospital Association.

Thus it is seen that the experience of medical practice with third-party agents is extensive in both duration and quantity in our own community, and there have been few doctors who have entered practice in recent years who have not engaged almost from the outset in some form of third-party practice, generally on a part-time basis. Local medical societies, as well as the American Medical Association Council on Medical Service, have achieved much during the past 15 years in encouraging and cooperating with insurance companies and service plans serving the best interests of their members. The underlying view is that there must be a common ground for providing voluntary medical insurance and service at reasonable rates to all Americans, especially those in the middle and lower income brackets.

Problems of Policy and Control

The appearance on the scene of a third party who will pay bills does not provide a complete solution to the problem. The American medical profession in very recent years made its position clear on this subject when it opposed the Murray-Wagner-Dingell bill, which sponsored socialized medicine with its offer to pay the bills. The medical profession made an emphatic reply of opposition to any attempt to federalize the practice of medicine in this country, as has been done in numerous other countries to the discredit and eventual deterioration of their medical standards. The medical profession now eyes the union third party not only with respect for what good it may accomplish in the health field by paying the bills of doctors, and hospitals, and others but also with alarm for what damage it may do to the standard of medicine if it attempts and succeeds, for reasons of self-aggrandizement or exploitation for power, in interfering with the first and second parties and the quality of the medical care extended. Some alarm results in part from the general unpopularity of labor unions and in part from the alterations in the traditional private patient-doctor practice. Doctors who have fancied themselves as rugged individualists and those who are neighborhood practitioners have seen their private patients disappearing to V. A. hospitals, industrial health centers, labor health centers, and elsewhere increasingly and are inclined, therefore, to oppose all plans as amounting to interference. Furthermore, there are those who are just as alarmed at the ultimate possibility of having powerful labor organizations or insurance companies dictate medical policy and medical financing as they were alarmed at the prospect of having the federal government dictate in this capacity.

To evaluate this labor third party, the Commission on Medical Care Plans of the American Medical Association has conducted several important surveys, including one with detailed descriptions of 29 union health centers that was reported in September, 1958. In their conclusions, the commission emphasized the generally high quality of medical care provided in the modern union health centers as compared to the standard of practice elsewhere in the United States.

What, then, becomes the future trend in third-party practice based on past and present experience and, specifically, what are the answers for those now completing their medical training and about to embark into this socioeconomic whirl of first, second, and third parties?

Would that I could borrow the wisdom and ability of the divinely inspired Moses, or Polonius, or the elder Germont. But, alas! I feel no security in predicting what is best. There are, however, some self-evident facts on which one can safely proceed.

Medical technology has improved immensely, and medical economics is changing in response to the greatest challenge of our time, viz., how to make this high quality of medicine obtainable by all. In this medico-economic reformation, the physician should be vigilantly responsible for opposing any change which will threaten to sacrifice the quality of medical achievement or its continued progress. He must also be mindful of all people's demand for this care and cooperate in planning with them and their third-party representatives how to make it available to them at reasonable cost.

False issues between physicians must be recognized and eliminated. The various techniques of medical practice today (solo, group, general, specialist) are all well-established, ethical, and legal and all are competent to provide excellent medical care. "Fee-for-service," "prepaid care," "salary contracts," and "third party" per se are all ethical and acceptable to organized medicine. It is not likely or necessary that any one system of practice will ever serve the various interests among the purchasers of medical care, and there is no place for competitive tensions between such participants.

Socialized (government) medicine must be opposed, although federal, state, and local governments are now widely engaged in medicine in the United States. Wherever voluntary groups and private enterprise can be encouraged to do the work, they deserve the cooperation and aid of doctors, since it is historically established that government domination of medicine leads to an inferior quality which Americans need not and have not settled for.

Recommendations

In my own experience and deliberations on the subject, I have concluded that the extraordinary achievement in the standard and quality of medical practice in the United States must be protected by regulation, so that it does not get lost in the many changes and influences to which it is being, and will be, subjected by the economy. This protection must be provided by those who have developed and practiced this quality, the doctors. I believe it is urgent that the American Medical Association recommend that any physician who accepts employment by a third party in caring for patients should have in his possession a contract which guarantees protection of the ethics of the profession and the delegation of medical policy and quality to the doctors. The American Medical Association should provide a type of contract for this purpose and it should include the following points: (1) assurance that the third party will not interfere in strictly medical matters dealing with traditional doctor-patient relationships; (2) assurance that professional qualifications for participating personnel be determined entirely by the profession, without lay interference; and (3) assurance that any disputes between medical and lay members will be settled through joint negotiations and then, if necessary, by impartial arbitration.

If the practice of third-party medicine will ultimately result in the domination and control by a business head, then such a practice would be not only unethical but also uneconomical and immoral. The only way to prevent such an undesirable result is for organized medicine to appreciate the impending danger and to take necessary steps, nationally and locally, to prevent the catastrophe. Will the future of medical practice be dominated by the business head of third-party organizations or by the guardians of the ethics of our profession?

THE LEISURE CORNER

THE RING COLLECTOR

The small band known to us as the finger ring has been an ornament and an expression of affection for thousands of years. The custom of wearing rings is probably as old as man. Rings have been found in ancient Egyptian tombs. They have long been symbols of a ruler's authority; kings gave their rings to trusted servants, and the ring gave the wearer the power of king's messenger. The Bible relates that Pharaoh placed his signet ring on Joseph's finger and that from this ring all men knew that Joseph had the sovereign powers of a king. The Romans probably originated the use of engagement or betrothal and wedding rings, a custom continued throughout the world to the present day.

Superstition surrounds the earliest legends concerning rings. Many people still tie strings around their fingers as a reminder. This tradition goes back to Mount Olympus, where Prometheus was said to have been chained for 1,000 years because he dared steal the sacred fire of heaven for mortal use. Jupiter took pity on Prometheus and bade him go free, with the proviso that he wear part of the chain around his finger, a reminder of his past servitude.

Primitive men would tie bands of sweet grass or narrow thongs of leather about the fingers of their women to remind them to remain faithful while they were away hunting game. Today, wedding rings are presumed to remind men and women that they are married. Rings are also worn to commemorate birthdays, school graduations, friendships, and memberships in organizations. Most rings are made of gold or other precious metals, plain, engraved, or set with stones. The most popular precious stone used in ring settings is the diamond, but others widely used are amethyst, topaz, turquoise, emerald, pearl, ruby, and sapphire.

Since human beings fear illness and death most, it can come as no surprise that throughout history rings have been worn to combat the possibility of the "evil eye," demons, witches, illness, and weakness, in fact every type of danger and disease. In warding off devils, madness, and death rings have long been regarded as possessing unusual curative and preventative powers. This was particularly true in the case of "cramp" rings. The fear of cramps was at one time as acute as the fear expressed by some swimmers today; the spasmodic and powerful contraction of the muscles was thought to produce permanent paralysis. But if a ring blessed by holy men were worn, it would ease the discomforts that ensued.

The collecting of rings and the study of their historical background has provided a fascinating hobby for many doctors because the association with disease has made the ring a symbol both therapeutic and psychological. Rings made of silver were once worn to cure fits and convulsions, rings made of elk hoof to cure epilepsy. Rings made of pure silver "of the moon," set in a piece of elk hoof under proper zodiacal signs and during the favorable conjunction of the planets, would prove "certain" to cure all diseases of the brain. Nasal congestion was treated by inserting medicated rings in the nostrils of patients.

Galen, who gained great fame as a general practitioner in Rome early in the 2nd century, wrote about a ring set with sard (a variety of cornelian) which weighed 20 grains and was supposed to insure deep and tranquil sleep and give protection against troublesome dreams and fearsome visions. Marcellus Empiricus, who practiced medicine in the 6th century, recommended a finger ring made of the hoof of a rhinoceros. He claimed that any patient suffering from "obstruction of the nerves" would experience relief by wearing the ring. Rings were also used as antidotes against poison. One example concerns a toadstone set in an open ring that would produce, it was claimed, a sensation of heat at the point of contact with the skin. Rings were also prescribed for respiratory tract disorders, notably sneezing and coughing. Infection, on the other hand, was treated by rubbing a gold ring firmly against the infected area, which would supposedly draw out the pus and alleviate the infection. Bilious and intestinal difficulties were not overlooked; a 6th century medical practitioner named Alexander Trallianus prescribed a type of ring that was proclaimed to cure kidney disorders, ulcers, and leprosy.

During the 16th century rings were worn on specific fingers in keeping with the occupation or personal inclination of the wearer. Thus, doctors wore rings on the thumb, merchants on the index finger, jesters on the middle finger, students (not lovers) on the annular finger, and lovers on the auricular (small) finger.

Ring collectors are constantly looking for interesting inscriptions to convey the sentiments of the giver of a ring. The following inscriptions were found at random in various books dealing with rings:

My giving this
Begins thy bliss.

Hearts content
Can ne'er repent.

And as this round is nowhere found
To flaw, or else to sever,
So let our love as endless prove,
And pure as gold forever.

MEDICAL LITERATURE ABSTRACTS

INTERNAL MEDICINE

Some Observations on the Malabsorption Syndrome, Based on the Use of Absorption Tests and Biopsy of the Small Intestine. P. J. Culver, J. A. Benson Jr., E. Strauss and C. M. Jones. Gastroenterology 36:459-466 (April) 1959 [Baltimore].

Since surgical exploration for biopsy of the small intestine is too formidable a procedure for the study of most patients with the sprue syndrome, the announcement by Shiner of a practical peroral biopsy tube is welcome news. Tools are now available for correlating the histology of promptly fixed specimens of intestinal mucosa with the absorptive functions of the small intestine. It was the aim of the studies described to compare the histology of "freshly fixed" surgical biopsy specimens of the small intestine with specimens taken via the Shiner tube from the same area, and in one case with postmortem material. Laparotomy was performed on 7 patients admitted with a diagnosis of sprue. Biopsies of a segment of the upper jejunum were performed without the application of clamps. In 3 patients the Shiner tube was passed just prior to the surgical biopsy, and a specimen was taken from the same area of the jejunum. The specimens were immediately fixed in 10% formalin in the operating room. One patient died of acute coronary thrombosis on the 11th day after laparotomy, providing material to show the changes of postmortem autolysis. An 8th patient with long-standing sprue did not have a laparotomy, but formalin was injected into the stomach and abdominal cavity immediately after death. The tissues were routinely blocked in paraffin, and sections were stained with hematoxylin and eosin. The histological studies on the intestinal specimens focused attention on the thickness of the mucosa (atrophy); aspects of the villi; arrangement, size, shape, and cytoplasm of the epithelial cells, and also various aspects of the nuclei of these cells; the lamina propria; and the submucosa.

In order to arrive at an approximation of the severity of morphologic change, the findings which might alter surface area, activity of the villi, epithelial cell function, and transport of foodstuffs away from the intestinal mucosa were evaluated. Then a composite estimate of the over-all histological defect was made. Results of the various biochemical tests for measuring intestinal absorptive function in each patient were likewise pooled to provide a composite estimate of the degree of malabsorption at the time of biopsy. All the patients studied had histological abnormalities of the small intestine, but the abnormalities found have not yet been demonstrated to be specific for sprue. There was dissociation between the severity of histological abnormality and the severity of malabsorption. This suggests that biochemical abnormalities of the intestinal mucosal cells may be the primary factor in the pathogenesis of the sprue syndrome.

Clinical and Pathological Studies of Joint Involvement in Sarcoidosis. L. Sokoloff and J. J. Bunim. New England J. Med. 260:841-847 (April 23) 1959 [Boston].

The authors report on 5 negro patients, a 33-year-old man, 3 women between the ages of 24 and 33 years, and an 11-year-old girl, with sarcoidosis in whom polyarthritis was a conspicuous feature. In 3 patients, arthritis was the initial or early manifestation of sarcoidosis. In each of the patients, systems other than the joints were involved in the sarcoidosis; 2 patients had sarcoid of the skin, 1 had erythema nodosum, 2 had uveitis and other ocular lesions, 4 had pulmonary involvement, and 4 had hilar adenopathy. Biopsy established the presence of noncaseating tubercles in the synovial tissue in 3 patients, and a submiliary granuloma suggestive of sarcoid in a 4th patient. In the 5th patient, the synovitis was of nonspecific histological nature. No fungi or acid-fast organisms could be recovered from the lesions. Although bone lesions were present in 3 of the 5 patients, the phalanges of the hands being affected in 2 and the phalanges of the feet in 1, the joint disease was not secondary to that in the bone and must be regarded as an intrinsic manifestation of the sarcoidosis. There is reason to believe that joint involvement of this sort is commoner than has been recognized previously, and that it has been mistakenly diagnosed as rheumatic fever or rheumatoid arthritis. Although erythema nodosum was present

The place of publication of the periodicals appears in brackets preceding each abstract.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover 1950 to date only, and no photoduplication services are available. No charge is made to members, but the fee for others is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

in only 1 of the 5 patients, it has been present in most of the cases reported by other workers. The frequency with which the lesion is associated with erythema nodosum invites speculation about the role of hypersensitivity in the pathogenesis of the disorder and also raises the question whether the arthritis and adenopathy of erythema nodosum are not themselves inherently related to sarcoidosis. Synovial biopsy may be of diagnostic value in such cases.

Agammaglobulinemia: Report of a Case of Historical Interest. H. B. Slavin, E. L. Alling and E. H. Keutmann. New England J. Med. 260:852-856 (April 23) 1959 [Boston].

The authors report the case of a male patient who was 13 years old when first seen in 1927 in the pediatric outpatient department of the Strong Memorial Hospital in Rochester, N. Y. He was underweight, complained of lassitude, and had had many sore throats. In 1933 he was seen at the Rochester General Hospital because of persistent, productive cough. He had left-side basilar bronchiectasis. A phrenicectomy was performed in 1934. In 1936 he was again admitted to the hospital, at this time for pneumonia. In 1937 a myringotomy was done for otitis media. From October, 1939, until his death in September, 1942, at the age of 29 years, he was hospitalized for 465 days, during 353 of which he had fever associated with cellulitis of the right thigh, antral sinusitis, acute proctitis, pneumonia, erythema nodosum, generalized arthralgia, a peritonsillar abscess, otitis media, appendicitis, bronchopneumonia, and parotitis. In November, 1941, he was found to have hypoglobulinemia. This was the first time that the plasma protein levels were determined. The electrophoresis apparatus was not available for study of the patient's plasma proteins until April, 1942. The electrophoretic analysis revealed a complete absence of the gamma peak.

The effect of hyperimmunization with horse serum, the patient's sensitivity to tuberculin and sulfathiazole, absence from the circulation of antibodies against a bacterium that caused repeated infection (type 19 pneumococcus), and failure to detect hemolytic complement in the blood serum, together with marked proliferation of the reticulum of lymph nodes and absence of plasma cells from all the tissues examined, are described and discussed. After a transfusion of normal plasma, gamma globulin did not appear to be removed from the blood stream faster than normal. The absence of a history of recurrent bacterial infections in infancy or early childhood and of detectable bacteremia during the frequent occurrence of such attacks in later life, together with the fact that the patient lived for 29 years, suggests that this case of agammaglobulinemia was the so-called acquired type.

Study on the Behavior of Bromsulphalein in Jaundice Diseases. I. Oddone, G. C. Bruno and P. C. Micheletti. Minerva med. 50:781-788 (March 17) 1959 (In Italian) [Turin, Italy].

The behavior of Bromsulphalein in 34 patients with different jaundice affections was studied. Eight patients had posthepatic (or obstructive) jaundice with no evident signs of hepatic damage, 5 had posthepatic jaundice with evident signs of hepatic damage, 5 had acute hepatitis, 3 had hepatocholangeitis, 11 had cirrhosis, and 2 had prehepatic jaundice. Bromsulphalein retention tests made in all the patients 30 minutes after the injection gave uniform results; the highest retention value (74%) was obtained in a patient with obstructive jaundice and no apparent hepatic damage, and the lowest value (16%) in a patient with acute hepatitis. Retention tests made 24 hours after the injection of Bromsulphalein yielded the highest values in patients with posthepatic icterus; values obtained in patients with hepatic damage were lower than those in patients with no damage. The lowest retention values were obtained in patients with cirrhosis. Intermediate values were obtained in patients with hepatitis. Values obtained in patients with hepatocholangeitis were similar to those obtained in patients with obstructive jaundice. Tests to determine the values of the constant of Bromsulphalein fall in the blood gave the lowest values in patients with posthepatic jaundice and no apparent damage; values increased markedly in patients with posthepatic jaundice and evident liver damage; the highest values were obtained in patients with cirrhosis. Intermediate values were obtained in patients with hepatitis and in those with hepatocholangeitis. Tests to determine the percentage of Bromsulphalein eliminated through the bile ducts yielded the highest values in patients with cirrhosis and in those with hepatitis. Values obtained for the remaining patients were high in those with jaundice with evident hepatic damage and low in those with no damage. The results obtained with tests to determine the period of persistence of Bromsulphalein in the blood and the quantity of coloring substance eliminated in the first 24 hours through the emunctory action of the kidney were comparable to those obtained with retention tests 24 hours after the injection of the drug.

Cirrhosis in Women: A Clinicopathologic Study. L. G. Stuhler, A. H. Baggenstoss and H. R. Butt. Gastroenterology 36:467-479 (April) 1959 [Baltimore].

The authors point out that de Josselin de Jong in 1931 defined cirrhosis on the basis of 3 common pathological characteristics: (1) degeneration and death of hepatic cells, (2) proliferation of connective tissue, and (3) regeneration of hepatic cells. These 3 criteria have been the subject of intensive investigation. Although some investigators have placed great emphasis on the connective tissue reaction, the authors have stressed the role of the regeneration of the hepatic cells, particularly in the form of the regenerative nodule, as the important physiopathological condition in cirrhosis after destruction of the parenchyma. Accordingly, they have accepted as examples of cirrhosis in women only those instances in which nodular regeneration was a feature of the reparative process. The natural history of some diseases is different according to the sex of the person afflicted. This study is concerned with cirrhosis as it affects women.

The material for this study included all cases in which cirrhosis of the liver in women, as defined above (except cirrhosis associated with obstruction of the biliary tract, congestive heart failure, hemochromatosis, or hyperthyroidism), was studied on autopsy at the Mayo Clinic during the years from 1924 to 1954, inclusive. There were 86 women with cirrhosis among a total of 5,515 women subjected to autopsy. The commonest type of cirrhosis found was the postnecrotic type (73 of 86 cases). The commonest cause of this type of cirrhosis was viral hepatitis (either infectious hepatitis or serum hepatitis). Cirrhosis in women, and particularly postnecrotic cirrhosis, was present at an earlier age than in men (average age, 45 years). Laennec's cirrhosis was found in women who were a decade or so older than the aforementioned women (average age, 55 years). Viral hepatitis in women may produce a granular type of cirrhosis, which bears some superficial resemblance to Laennec's cirrhosis but which can, in most instances, be distinguished histologically from typical Laennec's cirrhosis. Alcoholism is the etiological factor most commonly found in Laennec's cirrhosis in women, as it is in men.

The time interval between the onset of hepatitis and the development of cirrhosis was as short as 9 weeks and as long as 20 or more years, but in the majority of cases studied cirrhosis developed within a 3-year period after hepatitis had been contracted. The development of edema and ascites in both types of cirrhosis and of jaundice in Laennec's cirrhosis generally indicated a poor prognosis. Laennec's cirrhosis in women, as in men, appeared to be most often a progressive disease of several years' duration. This type of cirrhosis was much more likely to be a subclinical pathological finding than was the postnecrotic or granular posthepatitis type of cirrhosis. Postnecrotic cirrhosis generally had a more rapid clinical course, with death ensuing within a shorter period after the liver had been injured. The clinical manifestations usually were more pronounced in this type. Thus, the incidence of latent cirrhosis of this type, as found at autopsy, was considerably less than that of Laennec's cirrhosis.

Peculiarities in the Course of Malignant Diseases of the Hematopoietic and Lymphoreticular Systems Under Treatment with Cytostatic Drugs. W. Siegenthaler, G. Keiser and H. U. Zollinger. Ztschr. klin. Med. **155**:568-601 (no. 6) 1959 (In German) [Berlin].

The authors attempted to ascertain whether, since the introduction of cytostatic drugs into the treatment of malignant diseases of the hematopoietic and lymphoreticular systems, changes have taken place in the clinical aspects of these diseases. They compared observations on 120 patients with these disorders, who were treated at clinics and hospitals in Zurich, Switzerland, during the years 1954-1957 when cytostatic drugs were used or were combined with roentgen irradiation, with those on an equal number of patients treated between 1947 and 1953 when cytostatic drugs were not used or were used only briefly and in not very potent forms. The fact that in the 4-year period ending in 1957 the same number of patients with these malignant diseases were treated as in the preceding 7-year period suggests increasing frequency, and this was the case with regard to the percentage of total admissions (from 0.6% to 1%). This increase, however, may be largely due to the fact that, with the availability of more and presumably better modes of treatment, practitioners refer more patients with these malignant diseases to the special clinics.

The 120 patients treated more recently included 29 with acute leukemia, 9 with chronic myeloid leukemia, 19 with chronic lymphatic leukemia, 23 with sarcoma of the lymphoreticular system, 10 with multiple myeloma, and 30 with Hodgkin's disease. Thus, there were 57 patients with malignant conditions of the hematopoietic system and 63 of the lymphoreticular system. The incidence during the preceding 7 years was largely the same, that is, there were 65 patients with malignancies of the hematopoietic system and 55 of the lymphoreticular system.

In comparing the 2 groups, it was found that under the influence of the cytostatic drugs the survival of patients increased, especially those with acute leukemia for whom mercaptopurine (Purinethol) was the cytostatic drug most often used. In chronic lymphatic leukemia triethylenemelamine (TEM) and, more recently, chlorambucil (Leukeran) were used. Nitrogen mustard was widely used in patients with malignancies of the lymphoreticular system and in those with Hodgkin's disease. In general, the number of patients with each type of disease was not large enough to arrive at a definite conclusion with regard to changes in the prognosis under the influence of the cytostatic drugs. These drugs did, however, produce some changes in the clinical course. Most noteworthy was the increase in serious complications, such as damage to the bone marrow, severe infections, embolisms, and others. The fact that 41% of the patients treated with cytostatic drugs died, not of malignant processes in the hematopoietic and lymphoreticular systems, but of other causes deserves serious consideration. While knowledge of these complications should not prevent further employment of the cytostatics, antibiotics and cortical hormones, which are suitable prophylactics, should be given, so that the potent cytostatics will not produce undesirable secondary effects.

Bone Marrow Embolism to Lung Following Sternal Puncture. J. H. Yoell. A. M. A. Arch. Path. 67:373-374 (April) 1959 [Chicago].

Red marrow emboli to the lungs have been known to occur in fatal cases of multiple fractures, but there has been only a single literature report showing that these emboli may also arise as the result of sternal puncture. The patient cited by Montgomery in 1951 died 6 hours after such a puncture. The author describes a second case, that of a 70-year-old man with a long-standing history of chronic pyelonephritis and renal failure. Autopsy confirmed the clinical diagnosis. An incidental microscopic finding consisted of a single, solidly lodged, red marrow embolus within a small pulmonary vessel. Clinical records disclosed that sternal puncture and aspiration biopsy with a Turkel needle had been performed 9 days before death.

Marrow embolism subsequent to sternal puncture is no longer merely theoretical. Such emboli may be bland and few (present case) or fatal and multiple (Montgomery's experience). Reported instances of red marrow embolism, judged to be the immediate cause of death, have been encountered with neoplastic and tuberculous pathological fractures of vertebrae and after thoracotomy. A somewhat different mechanism, namely, bone marrow infarction, has led to fatal red marrow embolism in a few cases of sickle-cell anemia and type C hemoglobin disease. Red marrow embolism to the lungs incident to needle aspiration of a marrow space adds another, although so far rare, risk to this common diagnostic procedure.

Cardiovascular Lesions of Scleroderma. A. Buzzi, A. Bertolotto, G. Buzzi and L. Yraola. Prensa méd. argent. 45:3281-3287 (Oct. 10) 1958 (In Spanish) [Buenos Aires].

A 61-year-old woman with diffuse scleroderma and vascular disorders of the type of Raynaud's phenomenon of 30 years' duration is reported on. Severe skin lesions occupied the forearms up to the upper third and the legs up to the middle third. The middle finger of the right hand had been amputated 2 years before consultation because it became gangrenous. On hospitalization, the patient had massive gangrene of the left hand and its 5 fingers and of the toes and borders of the right foot. Roentgen-ray examination of the chest showed prominence of the aorta and of the root of the pulmonary artery; similar examination of the hands, arms, and legs showed calcinosis of the fingers, elbow, and knee joints. The calcium metabolism was normal. The electrocardiographic changes corresponded to those of ventricular hypertrophy and necrosis of the lower surface of the myocardium. An anatomicopathological examination of the hand, surgically removed, showed thrombosis of the digital arteries and lymphocytic and monocytic infiltration and edema of the arterial walls of the palmar arteries.

Diffuse scleroderma is a visceral disease which develops in association with arthropathy and skin lesions. The disease involves mainly the lungs and the cardiovascular system. Peripheral vascular disorders of the type of Raynaud's phenomenon are typical and constant; they appear early in the course of scleroderma. Electrocardiographic changes showing either overload or hypertrophy of the right ventricle are frequent. The ventricular abnormality is due to hypertension of the pulmonary artery. The extent of the electrocardiographic changes depends on the severity of the cardiovascular disorders.

Radioactive Phosphorus in the Treatment of Chronic Leukemias: Long-Term Results Over a Period of 15 Years. E. H. Reinhard, C. L. Neely and D. M. Samples. Ann. Int. Med. 50:942-958 (April) 1959 [Lancaster, Pa.].

From January, 1942, until busulfan (Myleran) came into use in 1953, practically all patients with chronic granulocytic leukemia referred to the hematology division of Washington University school of medicine for therapy were given radiophosphorus (P^{32}) as the primary treatment. Similarly, from January, 1942, until 1955, when chlorambucil (Leukeran) came into use, most of the patients with chronic lymphocytic leukemia were treated with P^{32}. Subsequent to 1953 and 1955, a progressively larger percentage of the patients with chronic granulocytic leukemia and chronic lymphocytic leukemia, respectively, were treated with Myleran and Leukeran. Data are presented concerning the results of therapy in 102 patients with chronic lymphocytic leukemia and in 118 patients with chronic granulocytic leukemia who were treated predominantly with P^{32}.

Forty-five per cent of the patients with chronic lymphocytic leukemia and 57% of the patients with chronic granulocytic leukemia showed a marked decrease in the size of enlarged lymph nodes during or immediately after the initial course of P^{32} treatment. The effects of the initial course of this therapy on spleen and liver enlargement have been presented graphically in such a manner as to simplify the comparison with the comparable effects of chemotherapeutic agents. If the leukocyte level was elevated at the time P^{32} therapy was started, a substantial decrease in the white blood cell count occurred in practically all cases. Of 57 patients with chronic granulocytic leukemia who had an initial thrombocyte count of one million per cubic millimeter, the platelet count decreased significantly after treatment in 22. Only 2 out of 23 anemic, nontransfused patients who had chronic lymphocytic leukemia showed an increase of 2 Gm. or more in the hemoglobin level after P^{32} therapy, whereas 22 out of 46 anemic, nontransfused patients who had chronic granulocytic leukemia had such an increase in the hemoglobin level. No patient with chronic lymphocytic leukemia who had an initial significant thrombocytopenia experienced an increase of the platelet level to normal after therapy, whereas such an increase occurred in 2 of the 8 patients with chronic granulocytic leukemia who had thrombocytopenia at the time P^{32} therapy was begun. The 5-year survival was 51% in patients with chronic lymphocytic leukemia and 12.5% in those with chronic granulocytic leukemia.

Segmental Ulcerative Colitis—Classification: Report of Nine Unusual Cases. E. J. Kurt and C. H. Brown. Am. J. Gastroenterol. 31:419-431 (April) 1959 [New York].

Segmental ulcerative colitis has been defined to include only that type of colitis that is limited to a segment or a portion of the colon, with no involvement of the terminal ileum or the rectum. Of 1,150 patients with ulcerative colitis seen at the Cleveland Clinic between 1940 and 1958, only 9 had true segmental ulcerative colitis. Cases in which involvement of the terminal ileum was questionable were excluded. The average period of follow-up was 5 years and 9 months. Medical treatment was given initially to 7 of the 9 patients. The condition of 4 patients improved satisfactorily, while in 3 the disease progressed and surgery was required. Of the 9 patients, 5 underwent surgery. Good results were achieved in all of them, although some patients required more than one operation. Two of the 3 patients on whom segmental resections of the involved areas were performed had no recurrence of colitis within 4 and 5 years.

The authors believe that segmental ulcerative colitis should be treated in much the same way as the commoner chronic ulcerative colitis is treated. Intensive and continuous medical management should be given adequate trial before surgical intervention is considered. Because of the bizarre involvement of the colon, all patients with segmental colitis should have several warm-stool examinations. A thorough course of antiamebic therapy is indicated even when the findings are negative. If adequate medical treatment fails to effect a remission, surgical intervention is indicated. Surgical treatment should remove completely the diseased tissue, but at the first operation preservation of normal intestine (i. e., segmental resection) is advisable. If there is incapacitating recurrence, subtotal colectomy with ileoproctostomy or total colectomy with end-ileostomy may be performed subsequently.

Flare-Up of Pericarditis Complicating Myocardial Infarction After Two Years of Steroid Therapy. W. Dressler. Am. Heart J. 57:501-506 (April) 1959 [St. Louis].

Pericarditis may occur as a complication of myocardial infarction and is then often associated with pleurisy and pneumonitis. The condition has been referred to as postmyocardial infarction syndrome. It has a characteristic tendency to recurrences, resembling in this as in other respects the postcommissurotomy syndrome. Both conditions are dramatically relieved by corticosteroids. Withdrawal of hormones is usually followed by a mild rebound. In occasional instances, however, the flare-up is severe and may occur repeatedly after months or even years of steroid therapy. In the 58-year-old man whose case is described, a remarkable sequence of events followed acute myocardial infarction. The initial febrile period was prolonged and was characterized by pleuropericardial pain and hemorrhagic expectoration. Pulmonary infarction was thought to be the cause. However, fever and chest pain of pleuropericardial type relapsed for 8 weeks, while hemorrhagic sputum was no longer present. Nor did the electrocardiogram reveal evidence of an extending myocardial lesion. The diagnosis was then changed to recurrent pneumonia. Numerous antibiotics failed to influence the febrile course. In the 8th week of illness, when the chest film indicated enlargement of the heart silhouette in addition to pleurisy, a postmyocardial infarction syndrome was diagnosed; steroid therapy was instituted and relieved all manifestations of the illness. However, repeated attempts at withdrawal of the hormones resulted in flare-ups of fever and chest pain. On 2 occasions, that is, 10 months and 2 years, respectively, after onset of steroid therapy, discontinuance of hormone administration produced symptoms and signs of pericardial effusion, pleuritis, and pneumonitis.

The observations on this patient represent another argument against the view that the postmyocardial infarction syndrome is of infectious origin. The author observed similar severe and recurrent withdrawal reactions in 2 other cases of postmyocardial infarction syndrome, in one of which signs of adrenal insufficiency developed, necessitating continuation of hormone therapy for a prolonged period of time. These drawbacks have to be borne in mind when the question of the use of hormones arises. Some patients with postmyocardial infarction syndrome do not require steroids, because the complication may subside spontaneously after a short time. Hormone therapy should be reserved for severe cases with prolonged course and intractable pain.

The Frequent Association of Other Body Tumors with Familial Polyposis. D. C. Collins. Am. J. Gastroenterol. 31:376-381 (April) 1959 [New York].

Fourteen new instances of an association between various secondary hard and soft tissue tumors and proved congenital polyposis are added to the literature. Twenty-nine other examples of an association of this familial colonic disease with other abnormal growths have been recorded during the past 20 years. Physicians are urged to remember the frequent association of these 2 pathological entities and to rule out, at the earliest possible moment, the possible presence in patients of an unsuspected instance of precancerous familial polyposis. Under such circumstances, if 2 specific diagnostic tests are performed (proctosigmoidoscopy and barium enema), many additional lives will be saved from needless death through the inevitable future development of carcinoma of the large intestine.

The Ion-Exchange Method of Determining Gastric Acidity. D. C. Mortimer. Canad. M. A. J. 80: 607-609 (April 15) 1959 [Toronto].

The author used Diagnex blue, a carbacrylic cation exchange resin, in which the hydrogen ions of the resin have been exchanged with azure A ions, a dye indicator, for the detection of the presence of free hydrochloric acid in the stomach of 110 patients, most of whom had various gastrointestinal disorders. The patients, who were in the fasting state, were given 2 tablets of 250 mg. of caffeine sodium benzoate, a gastric secretory stimulant, and one hour later they received Diagnex blue granules (2 Gm.). A urine specimen was taken before the ingestion of the Diagnex blue granules, and 2 hours later a second urine specimen was collected. If free hydrochloric acid were present in the stomach, azure A was released after the oral ingestion of Diagnex blue, and the dye displaced by free hydrogen ions was absorbed in the small intestine and excreted in the urine, where it could be readily detected by the blue or green color it imparted. The results of the Diagnex tests were compared with those of intubation gastric analysis performed with alcohol and histamine in these patients.

Of 39 patients with proved duodenal ulcers, 38 showed free acid and 1 was achlorhydric as revealed by the results of the ion-exchange test, while intubation gastric analysis was negative for free hydrochloric acid in 5 patients. There were no discrepancies between the 2 tests in 8 patients with gastric ulcer. In 21 patients with pernicious anemia, 6 patients with gastric carcinoma, and 4 patients with gastric atrophy proved by biopsy, achlorhydria was revealed by both intubation and tubeless tests. Six patients who had undergone subtotal gastrectomy had positive results from the qualitative ion-exchange test, but one of them failed to show free acid by intubation gastric analysis. Of 26 patients without known gastrointestinal disease, 3 had negative results from the intubation test, while the Diagnex test gave positive results. The qualitative ion-exchange test thus showed a high degree of correlation with intubation gastric analysis. The Diagnex test is a reliable method of differentiating patients with achlorhydria from those secreting free hydrochloric acid. Since intubation is not necessary and because of the simplicity of participation by the patient, ease of interpretation, and cheapness, this method is valuable in the assessment of gastric acid secretion.

Léri's Pleonosteosis: A Study of a Family with a Review of the Literature. J. G. Rukavina, H. F. Falls, J. F. Holt and W. D. Block. J. Bone & Joint Surg. 41-A:397-408 (April) 1959 [Boston].

The typical features of Léri's pleonosteosis, which is a hereditary syndrome, appear to be shortness of stature, Mongoloid facies, short spade-like hands, broad thumbs in valgus position, genu recurvatum, and limitation of motion of the articulations of the body. Pfaundler-Hurler's syndrome, Morquio's disease, and congenital syphilis are most frequently misdiagnosed as Léri's pleonosteosis. This report is concerned with what is believed to be the first American family to exhibit this rare entity. A pedigree, including 4 generations of 21 Caucasian members, was drawn up. It was reported by the relatives that the grandfather of the propositus exhibited the pathognomonic deformity of the hands and feet. His gait was shuffling, and progressive limitation of motion of the joints gradually developed. The mother of the propositus had marked deformities of various joints. Palmar fascitis was present in both hands, in addition to thickening of the fascia of the forearms. Broad thumbs and large toes were associated with flexed, short, stubby fingers and toes. Limitation of motion was found in the neck, shoulders, hips, knees, and elbow joints. The mother walked with short steps. Function of her hands was impaired.

The propositus was an intelligent woman, 43 years of age. The fingers of both her hands were markedly deformed, with flexion deformities, thickening and shortening of the phalanges, and marked limitation of motility. There were flexion deformities of all the toes, with limitation of motion. The range of motion of the elbows, knees, hips, and shoulders was also decreased, while in the neck rotation and flexion were markedly limited. One brother of the propositus was unable to walk with the heels on the ground. He had arthritis of the neck, hands, and wrists and was unable to make a fist, although his hand grip was strong. A similar clinical picture was observed in another brother. These siblings all had a mild Mongoloid slanting of the palpebral fissures; strabismus was present in the sister and one brother. One son of the propositus was free from symptoms of Léri's pleonosteosis, but the other son had most of the symptoms of the syndrome manifested in his antecedents. The most striking osseous abnormality in this family has been the bizarre enlargement of the posterior neural arches of the cervical vertebrae. The hereditary transmission of the gene responsible for Léri's pleonosteosis appears to be autosomal dominant, exhibiting fairly good penetrance and considerable variation in expressivity. Examination of more autopsy material will be required to understand better this syndrome.

Systemic Candidiasis and Endocarditis Due to C. Tropicalis. N. K. Conn, G. P. Crean, A. F. Maccabe and N. Maclean. Brit. M. J. 1:944-947 (April 11) 1959 [London].

The authors report the occurrence of systemic candidiasis due to infection with Candida tropicalis in a 61-year-old woman with dyspepsia of 20 years' duration. On admission to the Western General Hospital in Edinburgh, the patient was grossly undernourished and had marked epigastric tenderness. She had chronic rheumatoid arthritis and a large gastric ulcer. She underwent gastrectomy of Billroth 1 type and was discharged 2 weeks after the operation in good condition, but rigor and vomiting 2 days later made readmission to the hospital necessary. She left the hospital 4 days later against advice, only to be readmitted again 4 days later because of a new attack of fever and vomiting. She was treated with streptomycin and penicillin, and because of persistent vomiting a laparotomy was performed. The stoma was found to be narrowed by a plaque of fibrous tissue projecting into the lumen, and the obstruction was successfully relieved. From the time of the third admission until death, which occurred 57 days later, pus cells were constantly found in the patient's urine, and Escherichia coli, Proteus vulgaris, and Pseudomonas aeruginosa were cultured from catheter specimens. During this period she received 28 Gm. of streptomycin, 28 million units of penicillin, and 8 Gm. of oxytetracycline. Her condition deteriorated, with severe arthralgia, inanition, and anorexia. Blood cultures made during the week preceding death yielded growths of C. tropicalis. A throat swab, a vulvar swab, and a urine specimen obtained 3 days before death yielded growths of C. tropicalis on culture. There was no clinical evidence of mucocutaneous candidiasis at this or any other time.

Autopsy revealed monilial endocarditis, which differed from other reported cases of this condition by (1) the species of the infecting organism (C. tropicalis), (2) the site of the endocarditis with only large vegetations in the right atrium where the blood entering from the inferior vena cava impinged on the endocardium, the valves being unaffected, and (3) the presence of abscesses in the myocardium and in the kidneys, indicating that the infection was septicemic. The case of this patient illustrates the various clinical factors predisposing to the occurrence of systemic candidiasis. Debility and prolonged antibiotic therapy were probably the most important factors in its development. Candida organisms may proliferate in the blood of a patient without any clinical signs of systemic moniliasis appearing other than pyrexia. Unexplained pyrexia occurring in patients with prolonged debilitating diseases, especially those in whom antibiotics and intravenous alimentation have been used, is an indication for culturing the blood in mediums suitable for the growth of fungi.

Symptomless Myelomatosis. G. P. Baker and N. H. Martin. Brit. M. J. 1:953-955 (April 11) 1959 [London].

The authors report on a 43-year-old woman with myelomatosis, in whom 4 years elapsed between the discovery of pronounced hypergammaglobulinemia and the development of signs and symptoms of this disease. The pleural effusion, which brought the patient under observation, was presumed to have been tuberculous and not related to the subsequent myelomatosis, since no further chest complications occurred and the patient's chest remained roentgenologically normal. During the 4-year observation period after this effusion, the patient seemed to be in normal health and carried out all her duties as a housewife. The only clinical abnormality was a mild, orthochromic anemia, which did not increase during this period. Electrophoretic analysis showed increase in gamma globulin, with the sharp peak characteristic of myeloma globulin. The patient's erythrocyte sedimentation rate was persistently increased during the 4 years she continued to attend the outpatients' clinic, until attacks of pain in the lumbar region of the spine and of fever caused her admission to the Mayday Hospital in Croydon, England. Radiography showed osteoporosis and slight collapse of the bodies of several lumbar vertebrae. Considerable albuminuria was observed for the first time, and Bence Jones protein could be detected in the urine. Neither radiotherapy nor chemotherapy with urethan, nitrogen mustard, and tetracycline seemed to influence the patient's illness. The patient died, and autopsy confirmed the diagnosis of myelomatosis by the finding of extensive medullary and extramedullary deposits of plasma cells. There was moderate edema of the lungs, but no evidence of tuberculosis.

Polycythemia and Hydronephrosis or Renal Tumors. J. H. Lawrence and W. G. Donald Jr. Ann. Int. Med. 50:959-969 (April) 1959 [Lancaster, Pa.].

The authors review literature reports suggesting a possible causal relationship between hypernephroma and polycythemia. They saw their first patient in whom hypernephroma was associated with polycythemia in 1940. Since that time, among more than 300 patients with polycythemia, they have seen 2 more with hypernephroma and polycythemia who died of hypernephroma, also one patient with hydronephrosis and fibromyxoma of the kidney and another with hydronephrosis of congenital origin, both of whom had polycythemia and in whom normal blood values resulted from nephrectomy. (The association of polycythemia and hydronephrosis had not been previously reported.) Forssell who was the first to advance the possible causal relationship between hypernephroma and polycythemia has accumulated 20 cases from observation and from the literature. Additional cases presented by Gros, by Conley, and in this report bring the total number with this combination to 27. While polycythemia is far from a constant finding in hypernephroma, and reports of single cases may have no statistical significance, the implication of a relationship is strong.

If one accepts a causal relationship between hypernephroma and polycythemia, then one might postulate an erythropoietic factor produced by the tumor tissue or by the tissue from which it arises. Available reports suggest that it is the exception, rather than the rule, that hypernephroma tissue produces an erythropoietic factor. The association of polycythemia with benign lesions, as reported by DeMarsh in a benign adenoma, by Forssell in polycystic kidneys, and by the authors in 2 cases of hydronephrosis, would seem to indicate that the renal tissue itself has a potential for producing this erythropoietic factor, or that renal involvement—benign, malignant, or infectious—in some unknown way can enhance or possibly cause a polycythemia. The authors briefly review recent experimental work which indicates that a humoral erythropoietic factor is possibly produced by the kidney. The concurrence of polycythemia with hypernephroma and other renal lesions, and particularly the correction of polycythemia after nephrectomy in several cases, would seem to give clinical support to the assumption that the kidney may be a possible source of, or essential to the activation of, a humoral erythropoietic factor, but the method by which this operates is not clear.

The Forme Fruste in Marfan's Syndrome. R. L. Golden and H. Lakin. New England J. Med. 260: 797-801 (April 16) 1959 [Boston].

Marfan's syndrome has been defined as an inherited, autosomal, and dominant connective-tissue defect, primarily involving the skeletal system, the cardiovascular system, and the eye and with multiple clinical manifestations. The skeletal deformities most frequently manifested are dolichostenomelia, arachnodactyly, pectus excavatum (funnel breast), and pectus carinatum (pigeon breast). Also common is the dolichocephalic skull, with long, narrow, pointed face and high palatal arch. Winging of the scapulas is frequently found, as well as hyperextensibility of the joints and pes planus. Ectopia lentis is the most frequent ocular manifestation, but myopia, coloboma, retinal detachment, corneal abnormalities, and congenital mydriasis have also been reported. Cardiovascular phenomena associated with the syndrome are dilatation of the aorta and pulmonary arteries, with resultant valvular regurgitation and dissecting aneurysm. Defect of the interatrial septum is also found in some cases.

The authors call attention to the familial occurrence of Marfan's syndrome, in which recognition of its atypical forms is of special importance. Four members of one family, each with some degree of the forme fruste (atypical form), are described. The first 2 patients were brothers, aged 10 and 7 years, respectively; the third patient was the 23-year-old half-sister of the 2 boys; and the fourth patient was the 50-year-old father of these children. It is pointed out that, when Marfan's syndrome and other hereditary conditions are being considered, the factor of genetic expressivity may be variable from individual to individual, determining the degree of severity of the disorder. Penetrance is the expression of "a statistical concept of the regularity with which a gene produces its effects." A gene may have complete or reduced penetrance, the latter producing the so-called forme fruste, as was true in varying degree of the family discussed. In the absence of the ocular manifestation of the disease (ectopia lentis) in the 2 boys, the identification of the forme fruste was based upon the skeletal and cardiovascular abnormalities and the familial occurrence of the disorder. While patients with Marfan's syndrome are often tall, the 2 boys presented were not. However, relative dolichostenomelia was noted clinically and radiologically, as well as an increase in the length of the extremities in relation to the trunk. It is the skeletal proportions that are important in the syndrome rather than the actual height. Defect of the interatrial septum was suspected in 3 of the cases (the father and 2 boys) and was confirmed at autopsy in one of the boys. The presence of pneumonia in the 2 male siblings confirms previous reports of its frequency in association with this syndrome.

Although knowledge of the manifestations of Marfan's syndrome is widely disseminated, too often only the syndrome in its classic form is diagnosed. The authors feel that the practitioner must be alerted to the forme fruste and the importance of family history and examination in arriving at a diagnosis. Early recognition of the syndrome will enable its graver aspects—for example, the cardiovascular lesions—to be treated. Moreover, study of the family of an affected individual would determine the extent of transmission of the disease. A patient with the forme fruste could transmit the full clinical syndrome.

Tietze Syndrome: A Report of Four Cases. A. J. McSweeney. Wisconsin M. J. 58:223-227 (April) 1959 [Madison].

Although Tietze reported the syndrome of painful enlargement of the costal cartilages in 1921, American reports on this disorder did not begin to appear until 1953, but since then at least 38 cases have been reported in the United States. The disorder has been variously referred to as painful nonsuppurative swelling of costochondral cartilages, chondropathia tuberosa, costochondral syndrome, costal chondritis, sternochondralgia, and prominent costal cartilages. Various forms of treatment have been employed. The application of heat locally and the use of analgesics may provide symptomatic relief. Deep x-ray therapy, nitrogen mustard, local infiltration with procaine, corrective postural exercises, use of bedboards, and surgical removal of the involved cartilage have been advocated. Since the costochondral syndrome is a benign and self-limited condition, therapeutic measures should not be too radical. The author found that oral steroid therapy is a simple and effective remedy. He presents the histories of 2 men, aged 35 and 22 years, in whom painful enlargement at the costochondral junction responded to the oral administration of prednisolone. After citing investigators who have resorted to the local injection of hydrocortisone in treatment of Tietze's syndrome, he tabulates 12 cases (including the 2 mentioned) in which steroid therapy was used.

The author also presents the histories of 2 women, aged 51 and 27 years, with painful enlargement of the costochondral junction, who were not treated with steroids. In the older woman, the discomfort was relieved by propoxyphene, and in the younger one it disappeared gradually without treatment. Since the results of treatment with oral administration of prednisolone compare favorably with those of local hydrocortisone injection, further trial of orally administered steroids in the treatment of painful nonsuppurative swelling of costochondral cartilages seems warranted.

SURGERY

Radiosurgical Treatment of Primary Malignant Tumors of the Base of the Tongue. F. Brunetti. Minerva chir. 14:207-212 (Feb. 28) 1959 (In Italian) [Turin, Italy].

Primary malignant tumor of the base of the tongue was present in 62 out of 1,438 patients with malignant tumors, who were hospitalized at the otorhinolaryngologic clinic of the University of Turin between 1936 and 1958. Spindle-cell carcinoma was present in 24 patients, basal-cell carcinoma in 18, reticulosarcoma in 2, and thyroid adenocarcinoma in 2. Most of the patients were from 50 to 70 years of age. At the time of admission, the lesion was localized at the base of the tongue, with involvement of adjacent anatomic structures, in 38 patients; the tumor invaded the epiglottis and pharynx in 15 patients, the palatine tonsil in 6, and the body of the tongue in 3. There were 36 instances of the vegetative type of tumor and 26 of the infiltrative type.

During the first period (1936-1949), of 24 patients with localized primary tumor at the base of the tongue, roentgenotherapy was given to 16; radium implantation, preceded by immobilization of the tongue by Soerensen procedure, was performed on 4; and a median pharyngotomy, followed by electrosurgical resection, was carried out in 4. Subglossopharyngolaryngotomy was performed on 4 patients with glossolaryngeal tumor, and radium implantation through the mouth was carried out in 2 patients with glossotonsillar tumor. During the second period (1950-1953), roentgenotherapy was given to all patients with primary malignant tumor of the base of the tongue and with involvement of the adjacent areas. A subglossopharyngolaryngotomy was performed on 2 patients with glossolaryngeal tumor. Radium implantation through the mouth, preceded by immobilization of the tongue by the Soerensen procedure, was carried out in 3 patients, and a median pharyngotomy, followed by electrosurgical resection, was performed on 2; all 5 patients had a primary malignant tumor localized at the base of the tongue.

During the third period (1954-1958), roentgenotherapy was the only procedure used in patients with primary malignant tumor of the base of the tongue and with involvement of the adjacent areas. This procedure was preceded in many instances by unilateral or bilateral exeresis of the lymph nodes. This method consists in administering a course of radiation in a total dose of 6,000 r of either radiocobalt (Co^{60}) or roentgen rays. Patients with primary malignant tumor of the base of the tongue alone have been recently treated under general anesthesia by a lateral buccopharyngotomy and exeresis of the lymph nodes, followed by radium implantation under direct vision. This method allows an accurate evaluation of the extent in width and in depth of the neoplastic lesion. Of 22 patients available for follow-up during the past 8 years, death involved 3 with glossopharyngeal tumor, 1 with tumor of the base and involvement of the body of the tongue, and 1 with tumor of the base of the tongue, who underwent lateral buccopharyngotomy. The survival data are too recent to warrant any interpretation.

Mitral Restenosis. G. C. Patterson and J. R. Marshall. Brit. Heart J. 21:174-176 (April) 1959 [London].

The authors report on 7 patients, between the ages of 23 and 41 years, who were operated on for mitral stenosis and in whom restenosis of the mitral valve was confirmed at a second operation. These patients were observed among 400 patients operated on for mitral stenosis at the Royal Victoria Hospital in Belfast, Northern Ireland. Symptoms recurred at intervals, ranging from 8 to 41 months, after the initial valvotomy. A second operation was followed by improvement in 6 patients. One patient failed to improve and died 3 months after the operation. In 4 patients no evidence of rheumatic activity was found during the period of observation before and after surgical intervention. It is suggested that rheumatic fever may not be the only causative factor concerned in mitral restenosis.

Diagnostics, Indications for and Operative Closure of Septum Defects of the Heart with the Aid of Hypothermia and Extracorporeal Circulation. F. S. P. van Buchem, J. Nieveen, L. B. van der Slikke and others. Arch. chir. neerl. 11:15-40 (no. 1) 1959 (In English) [Arnhem, Netherlands].

The authors discuss the pathological anatomy of atrial septal defects (A. S. D.) and of ventricular septal defects (V. S. D.), the clinical picture of A. S. D. and the indications and contraindications for the surgical treatment of A. S. D., and the clinical picture of V. S. D. and the indications for surgical closure of V. S. D. Aids used in the operative closure of A. S. D. and V. S. D. are evaluated, particularly those used in the Groningen Thorax Center. After outlining the technique used in the closure of septal defects of the heart, the authors tabulate and discuss data on patients treated by them. In 40 patients with isolated septal defects (32 A. S. D. and 8 V. S. D.), they used extracorporeal circulation 14 times (6 times in A. S. D. and 8 times in V. S. D.). The other patients with A. S. D. were operated on with the aid of hypothermia. There were 4 deaths, 1 in a patient with A. S. D. and 3 in patients with V. S. D.

The authors feel that under hypothermia of from 29 to 30 C (84.2 to 86 F) not too complicated atrium secundum defects can be closed with relative safety. In the Groningen center the heart-lung machine of Lillehei-De Wall functioned satisfactorily in 14 children whose weight did not exceed 20 to 25 kg. (44 to 55 lb.), with a minute volume of 50 to 70 ml. per kilogram of body weight. The greater minute volumes required for larger patients is possible with the Lillehei apparatus, but in the Groningen center experimental studies are being carried out to determine what combination of oxygenators and pumps will give the best results. It is an established fact that success depends not only on the type of machine but equally on good teamwork. There are many problems still to be solved, but it may be assumed that further progress will be made in intracardiac surgery. Particular attention will have to be paid to the problems of hemolysis, destruction of thrombocytes, defibrination, fibrinolysis, and denaturation of proteins during perfusion.

The use of potassium citrate to arrest the heart may sometimes have more disadvantages than advantages by causing a delay in the recovery of the myocardium. The construction of the heart-lung machine must be greatly simplified. A minimal perfusion might be sufficient if a substance could be found with a reversible effect on the oxidation processes within the tissues. The combination with hypothermia, even if cooling is not so drastic as formerly, still involves the risk of a possible ventricular fibrillation. Although it is possible to stop this by means of a defibrillator, the subsequently necessary massage of a heart in which repairs have been carried out seems less desirable, especially if Ivalon has been used to cover the defects. In the repair of defects of the atrial septum the authors used a chemically controlled hypothermia of ± 30 C (86 F), and the results were favorable. Metabolic acidosis could be corrected by the intravenous administration of 4.2% of sodium bicarbonate, while the anesthetist regulated his ventilation technique according to the results of the chemical investigation.

Semeiology of Substernal Adenoma of the Thyroid. W. O. Lodge. A. M. A. Arch. Otolaryng. 69:419-423 (April) 1959 [Chicago].

Substernal adenoma is of insidious onset and of long duration. Although it is comparatively rare, it enters into the differential diagnosis of cancer of the lung but has a far better prognosis. In the course of numerous consultations and 325 biopsies and tracheal decompressions, the author met with 7 cases in which goiters were not palpable in the neck but were occult and intrathoracic. In 1 patient the goiter was inoperable, but 6 patients were operated on successfully and survived. The author reviews the manifestations of substernal adenoma in the light of recent studies by Soulas and Mounier-Kuhn; these investigations have dispelled the idea that early substernal adenoma produces no symptoms but dyspnea on exertion. He now realizes that to look only for respiratory symptoms is a mistake.

As to where one must look for the first signs of retrosternal adenoma, he says that a review of his own cases has convinced him that the answers are in the veins and in the manifestations of venous back pressure. In this connection he points out that another investigator observed hemoptysis in 3 of 15 cases. The trachea derives its blood supply from the inferior thyroid arteries. In the presence of substernal adenoma the inferior thyroid arteries, innominate veins, and superior vena cava soon become congested, as evidenced by distention of the superficial veins of the neck and thorax.

The author mentions the case of a pregnant woman in whom venous congestion of the head and neck, as well as radiology, led to the diagnosis of substernal adenoma of the thyroid. He also cites the case of a colleague who had dilated capillaries on the face and neck, which turned blue in cold weather. Within the nose a vascularized area on the nasal septum was evidently responsible for epistaxis, which caused the patient's admission to hospital. Tomograms demonstrated a large calcifying soft-tissue mass at the level of the thoracic inlet; this mass compressed the right lateral wall of the trachea. The radiologist suggested that a similar picture may be presented by a calcifying adenoma of the thyroid. At operation a calcified adenoma of the thyroid was excised. Investigation of epistaxis or hemoptysis may bring to light this occult but innocent tumor, which may be dealt with by surgical intervention with minimal mortality.

Treatment of Cancer of the Lung. C. Crafoord. Acta Unio internat. contra cancrum 15:443-447 (no. 2) 1959 (In English) [Louvain, Belgium].

The author believes that the most important diagnostic procedure in the detection of cancer of the lung is unquestionably conventional roentgenologic examination. As soon as any patient has clinical signs or symptoms suggestive of development of bronchial carcinoma, his chest should be x-rayed. If a tumor is in the process of development, the chest films will give valuable guidance with respect to both its localization and its etiology. The bronchoscopist can, in a large percentage of cases, provide the pathologist with specimens which permit a microscopic diagnosis. In 80% of all patients treated by the author, biopsy was possible. In those in whom investigation by biopsy is not possible, exploratory thoracotomy should be performed. This applies even if such measures as sputum examination, examination of local bronchial washings, and needle biopsy give negative results.

All the patients treated by the author underwent thorough clinical and laboratory examinations, as well as tests of pulmonary and cardiac function and roentgenologic investigation, before the question of operation was decided. Patients in whom distant metastases which could not be removed surgically were present were considered to have inoperable disease. This also applied to those whose ventilatory function was impaired. When circulatory disturbances were present, the patient's tolerance to blocking of the pulmonary artery on the affected side was tested, both at rest and during exercise, before operation was recommended. If investigation indicated that there was a considerable risk of cor pulmonale, surgery was advised against. Despite roentgenologic examination of the thorax and other organs, as well as of the skeleton, it was not always possible to diagnose the presence of distant metastases, and for that reason exploratory operation was performed in a large percentage of cases. Advanced age was also considered to be a contraindication for surgery.

In carrying out this operative procedure, each pulmonary lobe was regarded as a separate unit. The decision to perform total extirpation of the lung, or lobectomy, has therefore been based on whether the cancer has spread to more than one lobe by direct invasive growth, or whether lymph node metastases were present other than locally in the hilar region of each lobe. Exceptions to this rule were only made when the patient was elderly or when the respiratory function had been greatly impaired. Palliative lobectomy was then performed, even when metastasis had taken place to lymph nodes beyond the hilar region of the lobe in question. In such cases, operation has been as radical as possible with respect to dissection of the lymph nodes in the hilus and mediastinum. Radical or superradical pneumonectomy with ligation of the intrapericardial vessels and resection of the pericardium and all areolar tissue, together with the mediastinal lymph nodes, has been done only in cases of invasive growth beyond the region of the lung, towards the mediastinum and pericardium. This operation has not brought about any marked improvement in the 5-year survival rate. It has instead shown a tendency to increase the primary mortality.

Certain Problems of Surgical Treatment in Cardiac Aneurysms. B. V. Petrovsky. Khirurgiya 35:33-39 (no. 4) 1959 (In Russian) [Moscow].

The author reports on 6 patients with cardiac aneurysm who were successfully operated on. In 3 of these the author used an original operation devised by him. The operation consists of utilizing a pedunculated diaphragmatic flap. The flap is laid on and sutured over the aneurysm. The advantages of the operation are the strengthening, on the one hand, of the sutured myocardial wall of the aneurysm with diaphragm muscle and, on the other, the resulting improvement of the blood supply of the myocardium. Attention is called to the fact that innervation and blood supply of the diaphragm and the pericardium are related to one another through the pericardiophrenic arteries and nerves. The "take" of the muscular diaphragmatic flap with the myocardium results in gradual compensatory adaptation of the flap and its participation in the work of the heart.

Early and Late Hemodynamic Effects of Mitral Commissurotomy. W. S. Lyons, R. G. Tompkins, J. W. Kirklin and E. H. Wood. J. Lab. & Clin. Med. 53:499-516 (April) 1959 [St. Louis].

The authors report the hemodynamic data from 9 women and 3 men, between the ages of 23 and 52 years, with mitral stenosis, who underwent mitral commissurotomy between April, 1951, and October, 1952, and who accepted catheterization of the right heart 3 times or more, i. e., one week before commissurotomy, 10 to 90 days after, and 8 to 30 months after satisfactory mitral commissurotomy. Although every patient in this series obtained definite clinical and objective hemodynamic benefit after mitral commissurotomy, each had some degree of residual stenosis after the operation. All the patients were followed up for periods ranging from 4½ to 6 years after the operation, and the clinical improvement was maintained by 9.

Evidence both clinical and objective (from repeated catheterization and operation) of the recurrence of the preoperative stenotic condition was found in 3 of the 12 patients 3 to 5 years after commissurotomy. Recurrence of stenosis cannot be clearly proved without cardiac catheterization soon after the operation to establish on an objective basis the actual degree of relief of stenosis obtained by the operative procedure. Both accuracy and completeness are essential in these measurements. When the measured and derived data from determinations of blood pressure and flow were compared with the clinical status of the 12 patients before and after operation, significant correlation was apparent.

Profound Hypothermia. C. E. Drew, G. Keen and D. B. Benazon. Lancet 1:745-747 (April 11) 1959 [London].

The authors report experiments on dogs which were performed in an attempt to produce profound hypothermia by blood stream cooling. A simple extracorporeal circuit containing 2 reservoirs, one to collect pulmonary venous blood from the left atrium and the other to collect systemic venous blood from the right atrium, was employed. The animals were anesthetized with thiopental sodium and succinylcholine, and were given nitrous oxide and oxygen from an automatic oxygenator. The chest of the animal studied was opened by bilateral transsternal thoracotomy, and a catheter as large as possible was inserted in the left atrium and connected by the pulmonary venous line to the left atrial reservoir. An appropriate pump was then started, and blood from the left atrial reservoir was passed through a cooling coil and then returned to a femoral artery through one head of the pump-unit. Blood from the systemic venous or right atrial reservoir was pumped through the other head of the pump into the pulmonary artery by way of a cannula inserted through a stab incision in the infundibulum of the right ventricle. Systemic venous blood was not cooled.

A small number of experiments was sufficient to show that with the use of this simple apparatus it was possible to induce profound hypothermia (from 37 C [98.6 F] to 8 C [46.4 F]) in 2 dogs, followed by complete circulatory arrest for 30 minutes, and then to rewarm them with recovery. In a second series the apparatus was modified with an improved heat-exchanger, instead of a coil, and pump-heads of the DeBakey type, instead of the sigmamotor pump-heads used in the previous experiments. To prevent sudden hypotension at the onset of partial left ventricular bypass, an adjustable clip was placed on the pulmonary venous line, so that drainage from the atrium could be controlled by the surgeon. The flow of chilled blood into the aorta was started slowly, and increased to its maximum of 50 to 70 cc. per kilogram per minute at the onset of right ventricular bypass. The rate of increase in flow through the extracorporeal circuit was governed by the blood pressure, which was kept at an arbitrary mean of 80 to 100 mm. Hg. Two of the 4 dogs in which cooling was carried out to 15 C (59 F), followed by a period of complete circulatory arrest lasting 20 to 45 minutes before rewarming, survived without evidence of neurological damage.

Profound Hypothermia in Cardiac Surgery: Report of 3 Cases. C. E. Drew and I. M. Anderson. Lancet 1:748-750 (April 11) 1959 [London].

Using the technique of inducing profound hypothermia with cooling to 15 C (59 F) described in the preceding paper, the authors operated on 3 children, a 12-month-old Mongoloid boy, a 4-year-old high-grade Mongoloid boy, and a 2½-year-old boy, all with congenital intracardiac defects. After a period of total circulatory arrest of 46 minutes, the first patient appeared to be recovering; 70 minutes after the chest had been closed, the infant was breathing spontaneously, moving all 4 extremities and swallowing. However, 45 minutes later this patient died of heart block after partial correction of a persistent atrioventricular canal of the complete variety. The other 2 patients survived. The 4-year-old boy had right atriotomy and ventriculotomy for obliteration of an atrial and ventricular septal defect. Repair of the latter necessitated resection of the medial cusp of the tricuspid valve and its resuture. In this patient the total circulatory arrest lasted 45 minutes. The second surviving patient had a repair of a ventricular septal defect which required circulatory arrest for 25 minutes. In none of the patients did ventricular fibrillation occur. Hemolysis was negligible, and there were no significant biochemical upsets. The survivors did not show any evidence of neurological or other damage and made uneventful recoveries.

Since this paper was submitted for publication, 4 additional patients have been operated on with the aid of profound hypothermia for the correction of intracardiac defects. One patient, an infant weighing 8 lb. (3.6 kg.), died 24 hours after the operation; his death was probably due to heart block. One of the 3 survivors was a 49-year-old patient who had complete cardiac arrest for 42 minutes at a temperature of 15 C. Greater experience may confirm the authors' growing belief that profound cooling with cardiac bypass will play an increasing part in intracardiac surgery at the expense of cardiopulmonary bypass at normal temperatures, with use of a pump-oxygenator.

Bilateral Internal Mammary Arteries Ligation in the Coronary Artery Disease. M. Battezzati, A. Tagliaferro and A. D. Cattaneo. Sc. med. ital. 7:463-485 (no. 3) 1959 (In English) [Rome].

Anastomotic connections exist between the coronary system and the internal mammary arteries. Ligation of both internal mammary arteries at the second intercostal space, i. e., beyond the origin of the main collateral branches, enhances the development of these anastomoses as a substitute collateral system in coronary disease. The mechanism of the vicarious action consists in diverting the blood flow from the mammary artery into its collateral branches, so that the total flow through the latter is increased; this is further intensified by coronary hypotension and myocardial hypoxia.

The degree of protection afforded by the bilateral ligation of the internal mammary arteries in coronary occlusion was studied in 50 dogs in which infarction was produced by ligation of the anterior descending branch of the left coronary artery at about 3 mm. from its origin. The animals were divided into 2 groups of 25 each; bilateral ligation of the internal mammary arteries was performed 15 minutes after the ligation of the anterior descending branch of the left coronary artery in both groups, and in the second group the bilateral ligation of the internal mammary arteries was performed at the level of the third intercostal space. The survival rate in the first group of animals was 80%, and in the second group it was 76%. Hemodynamic studies carried out on the dogs have shown that the ligation of the mammary arteries tends to restore to normal the circulatory conditions seriously altered by coronary occlusion.

Bilateral ligation of the internal mammary arteries was performed at the second intercostal space on 207 men and 97 women, between the ages of 33 and 83 years; of these 304 patients, 151 (49.6%) had angina pectoris and 153 (50.4%) had myocardial infarction, associated or not associated with angina pectoris. The coronary disease was accompanied by symptoms of cardiac failure in 230 patients (75.6%). Of the 304 patients, 288 (94.7%) were improved within 30 days after the surgical intervention, 15 (4.9%) were therapeutic failures, and 1 (0.3%) had died. The improvement generally persisted for a period ranging from 1 month to 3 years after the surgical intervention. Twelve patients died within this period. Of the total number of 13 deaths, 8 resulted from heart disease and 5 from extracardial causes. None of the patients died in the course of the operation. One hundred ninety-five patients (64.1%) showed electrocardiographic improvement affecting the voltage, S-T segment, T wave, and rhythm. The bilateral ligation of the internal mammary arteries, like any other surgical procedure causing revascularization, does not provide the patient with a new heart but has the advantage of offering the same results as other more complex and radical surgical procedures, with less difficulty for the surgeon to perform and with less risks and trauma for the patient.

Bilateral Internal Mammary Artery Ligation and Coronary Artery Occlusion. R. Hardin, H. B. Shumacker Jr., Chien Sheng Su and G. Bounous. Surg. Gynec. & Obst. 108:518-522 (May) 1959 [Chicago].

Healthy mongrel dogs were used for the experiments described. In one group of animals, ligation of the internal mammary arteries was performed through a transverse midsternal incision at the level of the second intercostal space. Both arteries were identified and divided between ligatures. Another group of animals was subjected to a similar incision and dissection, but no ligation was performed. In both groups of animals, ligation of the anterior descending branch of the left coronary artery was carried out one month later. In a third group of animals subjected to no previous surgery, the same coronary artery ligation was accomplished. Postmortem study was performed when the dogs died or when they were killed 7 days after coronary division.

These animal experiments failed to demonstrate that bilateral ligation of the internal mammary arteries performed one month previously provided any protection against division of the anterior descending branch of the left coronary artery. The survival rate was quite as good in untreated controls and in animals previously subjected to a sham operation. No increase in retrograde coronary flow was demonstrated in animals a month after bilateral internal mammary ligation as compared with animals in the other 2 groups. The authors conclude that these experiments and a survey of those reported in the literature yield no convincing experimental basis for applying the procedure of internal mammary artery ligation to man.

Experimental Evaluation of Internal Mammary Artery Ligation as a Method of Myocardial Revascularization. J. H. Vansant and W. H. Muller Jr. Surgery 45:840-847 (May) 1959 [St. Louis].

Three experimental approaches were utilized to determine whether or not internal mammary artery ligation increases collateral blood flow to the heart. 1. The mortality rate following ligation of a major coronary artery was employed to judge the degree of protection afforded the heart. A mortality rate of 90% occurred in the control group. Following ligation of the internal mammary arteries, the mortality rate was 70%. These results are not indicative of statistically significant myocardial protection. 2. A technique was devised to measure simultaneously pressures in the internal mammary artery and pressures and flows in a tributary of this vessel which is comparable to the pericardiacophrenic artery. Occlusion of the internal mammary artery distal to the tributary did not significantly affect the pressures in the internal mammary artery or in the tributary; neither did it appreciably increase the volume flow through the tributary. 3. The third method of evaluation consisted of measuring the acute effects of bilateral internal mammary artery ligation on the retrograde pressures and flows of an occluded coronary artery. No significant change in either measurement occurred when the internal mammary arteries were totally obstructed. No evidence was obtained from these studies to demonstrate that bilateral internal mammary artery ligation increases the collateral blood supply to the myocardium.

Coronary Heart Disease: III. Chronic Arrhythmias as Influenced by the Beck Operation. B. L. Brofman, J. F. Bond and D. S. Leighninger. Am. J. Cardiology 3:618-625 (May) 1959 [New York].

The authors selected from 350 patients, who underwent the Beck operation for relief of coronary artery disease, 20 in whom a chronic arrhythmia was observed as a prominent manifestation of coronary heart disease before the operation, and who were followed up for 1 to 6 years after the operation. In 15 of these 20 patients ventricular extrasystoles were prominent before the operation; auricular extrasystoles were present in 3, and sinus tachycardia in 2. Long-term follow-up revealed significant clinical improvement, associated with abolition or diminution of the arrhythmia in 17 (85%) of the 20 patients. Within the limits of this study, these arrhythmias represented a reliable index of myocardial ischemia in a given patient with coronary heart disease. The consistent abolition of the arrhythmias with concomitant clinical ("subjective") improvement constitutes confirmatory ("objective") evidence of the beneficial effect of the operation. During and after the operation, administration of digitalis had a specific inotropic and chronotropic influence on the heart, with decreased instability, reduced incidence of paroxysmal arrhythmias, and increased stroke output. Digitalization is, therefore, recommended before the surgical intervention for coronary artery disease.

Sarcoma of Esophagus: Surgical Treatment. J. Borrie. J. Thoracic Surg. 37:413-426 (April) 1959 [St. Louis].

In a search of the literature the author found 19 patients who had been operated on for esophageal sarcoma. He reports another case, that of a 63-year-old man with a polypoid fibrosarcoma of the lower third of the esophagus; this condition was detected 8 months after a transthoracic repair of a hiatus hernia, previously performed at another hospital, and 1 month after the onset of dysphagia. The patient was subjected to a partial esophagogastrectomy, with esophagogastrostomy and block dissection of the regional lymph nodes, at Dunedin (New Zealand) Hospital, and is now well, 6 years after the operation. The history of this patient has suggested that the tumor was not present at the time of the radical operation for hiatus hernia. Its detection 8 months later emphasizes the fact that esophageal tumors often do not cause symptoms, and that sometimes they do occur in association with hiatus hernia. It is important that all patients presenting hiatus hernia should be subjected to esophagoscopy before the operation. The recurrence of dysphagia after a successful herniorrhaphy should not be ignored, but should be promptly and repeatedly investigated by esophagoscopy as well as by esophagrams. The possibility of sarcoma of the esophagus should be borne in mind in patients manifesting dysphagia after an apparently successful hiatal herniorrhaphy. If the tumor is polypoid in type, and if it is detected early, the chances of recovery after a successful resection are excellent.

Pulmonary Abscess: A Study of 70 Cases. D. N. Pickar and W. F. Ruoff. J. Thoracic Surg. 37:452-459 (April) 1959 [St. Louis].

The authors report on 70 patients with pulmonary abscesses treated at the Veterans Administration Hospital in Louisville, Ky., during the past 10 years. The patients were males, 59 whites and 11 Negroes, ranging in age from 20 to 60 years. Patients with abscesses resulting from tuberculosis, fungous or parasitic infection, and carcinoma were not included in this study. The duration of symptoms before hospitalization varied from 1 month or less up to 26 months. Sensitivity studies were performed on the sputum of all the patients. The choice of the antibiotic varied. Penicillin alone was administered to 21 patients; penicillin with tetracycline, to 12; penicillin and streptomycin, to 3; tetracycline alone, to 1; and streptomycin combined with isoniazid, to 1 (because of the possibility of tuberculosis). Forty-four patients were treated with medicaments. Thirty-five patients were considered to have closed cavities after 10 to 120 days of this medical treatment. The cavities of the remaining 35 did not close, and 24 of these were operated on. Twelve patients in all died, representing a mortality of 17.1%.

Pulmonary abscesses are considered to be primarily a medical problem, and if even a slight improvement is obtained during treatment with medicaments, it should be continued for a prolonged period. Surgical procedures should be carried out only on patients in whom medical treatment has failed. The advent of antibiotics and improvements in anesthetization and surgical techniques have substantially improved the prognosis in patients with pulmonary abscesses. A long period of hospitalization is required, however, and the disease remains a grave problem.

Surgical Diagnosis of "Chronic Pancreatitis" and Chronic Relapsing Pancreatitis. M. A. Birnstingl. Brit. M. J. 1:938-943 (April 11) 1959 [London].

The authors report on 18 men and 4 women with nonmalignant chronic pancreatic disease, the presence of which was confirmed at surgical exploration. These 22 patients were divided into 2 groups, one consisting of 11 men and 1 woman, whose ages at the onset of symptoms varied between 41 and 82 years, and the other consisting of 7 men and 3 women, whose ages at the onset of symptoms varied between 18 and 65 years. Jaundice of obstructive type was present in 10 of the 12 patients in the first group. The duration of this symptom before operation varied between 2 and 18 weeks, and it formed the main indication for surgical exploration. The pathological diagnosis of "chronic pancreatitis" was based on the findings at surgical exploration, supplemented by a surgical biopsy including small pieces of tissue removed from the surface of the pancreas in 8 patients. Surgical procedures in 10 of the 12 patients were undertaken to relieve biliary obstruction by internal drainage. The remaining 2 patients did not undergo further surgical intervention. The clinical findings in this group of 12 patients were strongly suggestive of malignant disease. This likelihood was supported by the age of the patients and the short duration of their illness. The findings at operation provided further presumptive evidence of the presence of carcinoma, since they included the presence of a tumor in the pancreas in 9 patients, 7 of whom had obstructive jaundice. Nevertheless, the histological report of "chronic pancreatitis" led to its acceptance as providing the most likely diagnosis of the true nature of the disease. All 12 patients died of carcinoma of the pancreas within 4 days to 3 years after exploration; only 2 patients survived more than 1 year. An important cause of error in the pathological diagnosis was a failure to recognize the structural effects of pancreatic ductal obstruction. The term "chronic pancreatitis" is an inaccurate description of this type of pathological change.

The clinical picture of the 10 patients in the second group was one of chronic relapsing pancreatitis. The average age of these patients at the onset of symptoms was 45 years, i. e., 15 years less than the average age of the patients in the first group. The clinical picture was supported by the macroscopic findings at exploration and by a postoperative survival time varying between 6 and 40 years. A barium-meal examination was carried out in 6 of the 10 patients, and changes in the configuration of the duodenal loop were observed in 5. Pancreatic calcification was present in 4 patients. The macroscopic and microscopic changes observed in pancreatic biopsy specimens obtained from 4 of the patients were consistent with the probable origin of these changes as a sequel to recurrent inflammatory incidents in the parenchyma. The evidence produced by other workers suggested that in a large proportion of cases the pancreatic calcification in relapsing pancreatitis occurs within the ducts and not in the parenchyma, representing an effect rather than a cause of the disease. In the author's patients with relapsing pancreatitis the effects of pancreatic ductal obstruction were not seen, but direct pancreatographic procedures were not considered justifiable in these patients, and, therefore, it was not possible definitely to exclude an obstructive causative factor.

Cancer and Diverticulitis of Transverse Colon: Coexistence. H. M. Moguillanes and M. G. Mendoza. Prensa méd. argent. 45:3290-3294 (Oct. 10) 1958 (In Spanish) [Buenos Aires].

The association of chronic diverticulitis of the transverse colon with cancer of that segment is rare. Each disease has an aggravating influence on the other. A man, 58 years old, with rectal disorders of long duration and acute anemia was hospitalized. During the previous 9 months the patient had had rectal hemorrhages, and he had lost 13 kg. (28½ lb.) in weight. Examination of the large intestine with opaque enema showed multiple diverticula in the transverse colon and a stricture at the center of the segment. An exploratory laparotomy showed chronic diverticulitis of the entire transverse colon and a tumor in the center of the segment. The tumor was the size of an orange and of a carcinomatous aspect and infiltrated the visceral serous layers. The operation to which the patient was subjected consisted of resection of the transverse colon and the ascending colon, including the tumor, with an anastomosis of the ileum and the descending colon. His immediate and late postoperative courses were uneventful, and he was discharged 3 weeks after the operation in satisfactory condition. The anatomicopathological examination of the surgical specimen showed a large number of diverticula in the colon and carcinoma of the mucosecreting type.

Intra-Aortic Nitrogen Mustard Therapy in Advanced Pelvic Malignancies. R. L. Byron Jr., B. P. Singh, H. R. Bierman and K. H. Kelly. Surgery 45:634-641 (April) 1959 [St. Louis].

Injection of a nitrogen mustard, such as mechlorethamine hydrochloride (HN_2), into the nutrient artery of a malignant tumor has been used as one point of direct attack. The studies described were designed to investigate the effect of intra-aortic nitrogen mustard therapy in advanced pelvic malignancies. The investigations were carried out by a team of surgeons, internists, anesthetists, and a radiologist. Thirty-four patients with advanced pelvic malignancies of various types comprised the material for this study. Carcinoma of the cervix, ovary, and rectum or sigmoid accounted for 27 of the 34 lesions. The diagnoses were confirmed by at least one biopsy. Thirty of these 34 patients had been previously treated by definitive radiation therapy and/or surgery. The remaining 4 patients had not received any previous therapy.

Thirty-one patients were subjected to a pelvic laparotomy. After manual exploration, the aorta, just above its bifurcation, and the inferior vena cava were exposed, and Penrose rubber drains were placed around them to serve as tourniquets. The arterial circulation in both lower extremities was occluded by femoral artery pneumatic tourniquets. After the occlusion of the femoral arterial circulation, a single injection of freshly prepared nitrogen mustard (HN_2) was rapidly given into the aorta just above its bifurcation. During and after the injection, the aorta and the inferior vena cava were occluded above the injected site for 5 minutes. This allowed maximum arterial concentration of the nitrogen mustard in the tumor-bearing area of the pelvis. After the 5-minute period all the tourniquets were released, and the abdomen was closed. Three patients were treated by the arterial catheterization technique in which the left brachial artery was used. The artery was exposed, and loops of rubber bands were placed around the vessel above and below the site for the opening of the artery. An incision was made through the wall of the artery, and the tip of the catheter was inserted and then guided into the descending aorta by roentgenoscopy to a point just above the aortic bifurcation. The catheter was left in place, and the patient returned to the ward. After the occlusion of the femoral arterial circulation, nitrogen mustard was injected through the catheter. The occlusion was maintained for 5 minutes after the injection and then released. The catheter was left in the artery 5 days without untoward effect.

The injection of nitrogen mustard into the nutrient artery has proved of some value in the palliation of advanced pelvic malignancies. Seven of 34 patients showed objective improvement; there were 3 postoperative deaths. Patients with malignant tumors localized to the pelvis, which are not amenable to surgery or irradiation, are suitable for intra-aortic nitrogen mustard therapy. This is particularly true when the tumor has involved the lateral pelvic walls. The final decision to utilize chemotherapy frequently must be made at the operating table during the exploratory laparotomy. The nitrogen mustard can be administered safely via the aorta in doses of 0.25 to 1.3 mg. per kilogram of body weight.

Carcinoma of the Corpus Uteri. W. Hawksworth. Acta Unio internat. contra cancrum 15:270-275 (no. 2) 1959 (In English) [Louvain, Belgium].

The author reports on 251 patients with carcinoma of the corpus uteri seen in the area department of obstetrics and gynecology at Oxford, England, between 1940 and 1957. Of these 251 patients, 220 were treated surgically, with an operative mortality of 60. One hundred sixty-five patients were followed up 5 years after the initial treatment, and 105 of these are still alive. Of the 151 patients in the follow-up group who were operated on, 124 showed no evidence macroscopically of extension of growth beyond the uterus at the time of operation, and 95 of these are living 5 years after the operation. There were, however, 27 patients with macroscopic evidence of spread beyond the uterus at the time of operation, and only 8 have survived 5 years. Of the 60 patients who died during this period, 38 had recurrence, but in the whole group of 251 patients only 3 had recurrence in the vaginal vault. The commonest sites of recurrence are the lymph nodes of the pelvic walls. The author considers that operation should include lymphatic dissection as a routine treatment. The increase in surgical risk is low, but the prognosis with positive pelvic lymph nodes is bad. The author claims a staging of the disease based on operative findings rather than the actual clinical classification.

Cytologic Diagnosis of Rectal and Colonic Conditions. B. M. Chapman. Gastroenterology 36:501-504 (April) 1959 [Baltimore].

This report is concerned with an analysis of cytological diagnosis in rectal and colonic conditions from material accumulated over a period of 10 years. A total of 877 smears from 746 patients were studied. The preparations were taken during sigmoidoscopic examinations when disease was seen or suspected. Ninety-two of the smears were positive, 2 falsely positive, 12 falsely negative, 10 suspicious, and 4 falsely suspicious. Of the 92 positive smears, 66 were proved by biopsy or examination of the surgical specimen to be adenocarcinoma, and 6 malignant adenoma. In 18 patients with positive smears, follow-up information could not be obtained. With the deletion of this group from the analysis, it is found that the accuracy of cytological diagnosis in this series was 77%. Study of the smears proved valuable as an adjunct in the diagnosis of other conditions of the rectum and colon, such as ulcerative colitis, amebic dysentery, bacillary dysentery, diverticulitis, and tuberculosis. The test appears to have its greatest value in the diagnosis of lesions between the splenic flexure and the rectosigmoid.

NEUROLOGY & PSYCHIATRY

The Treatment of Tuberculous Meningitis in Adults from 1947 to 1957. F. Russi, G. Rossi and R. Bonazza. Minerva med. 50:606-618 (Feb. 28) 1959 (In Italian) [Turin, Italy].

Fifty-five patients, 10 to 66 years of age, with tuberculous meningitis were treated in a hospital in Ancona, Italy, from 1947 to 1957. The patients, according to the treatment given, were divided into 3 groups. The first group consisted of 28 patients, seen between 1947 and 1951, who were treated with streptomycin given intramuscularly and intraspinally; 6 of these patients recovered. The second group consisted of 12 patients, seen between 1952 and 1954, who were treated with the same drug as the patients of the first group, with the addition of isoniazid; 8 of these patients recovered. The third group consisted of 15 patients, seen between 1955 and 1957, who were treated with the same drugs as the patients of the first and second groups, with the addition of cortisone and aminosalicylic acid given intravenously; 14 of these patients recovered. None of the 28 patients who recovered permanently presented late side-effects, owing to treatment on observation 1 or 2 years after the end of the initial treatment. At these follow-up examinations, however, 2 patients presented spastic paresis and 1 a mild Jackson's syndrome with electroencephalographic focal signs. No relapses occurred after treatment in patients of the first and second groups; 2 early relapses occurred in patients of the third group, but they recovered after further treatment.

The authors believe that a combination of streptomycin, isoniazid, cortisone, and aminosalicylic acid represents today the best treatment for adults with tuberculous meningitis. Such treatment is useful in avoiding the risk of late intolerance or resistance to isoniazid, which might cause a relapse of meningeal symptoms or affect unfavorably the course of the disease, as occurred in the one patient of the third group who died. Moreover, the authors believe that aminosalicylic acid given intravenously in large quantities is especially useful in the initial hematogenous or bacillogenous stage of tuberculous meningitis.

Effects of Delayed Anticoagulant Therapy on Experimental Cerebral Infarcts. A. F. Peterman, K. G. Wakim, G. P. Sayre and others. J. Neuropath. & Exper. Neurol. 18:263-269 (April) 1959 [New York].

Although anticoagulant therapy has been used with some success in the treatment of certain types of cerebrovascular disease, a great deal of uncertainty exists about the effects of such treatment on completed cerebral infarcts. Several methods have been described by which cerebral infarcts can be produced in dogs. Since it has been shown that a cerebral infarct undergoes its most distinctive histological change by the fourth day, it was decided to start anticoagulant therapy on the third day after the production of cerebral infarction, aiming at the establishment of a reduction of prothrombin activity to the therapeutic range by the fourth day after infarction. Homologous blood clots were used to produce intracranial arterial occlusion, because this method causes cerebral infarction in the majority of animals associated with a relatively low mortality rate; also, such infarcts resemble embolic infarcts found in humans. Approximately 48 hours prior to operation, 5 ml. of blood was withdrawn from each dog and allowed to clot and stand at room temperature in a sterile test tube. Cerebral infarcts then were produced by injection of these homologous blood clots into the internal carotid artery via the common carotid artery exposed through an incision in the neck. In the animals in which a satisfactory embolic lesion was produced, the signs and symptoms of cerebral infarction were evident when the animals recovered from anesthesia. Only those dogs which showed definite signs of cerebral infarction, which survived for 3 days after the procedure, and which were otherwise in good health were included in this study.

A total of 24 dogs with experimentally produced cerebral infarcts were given anticoagulants, beginning on the third day after the induction of infarction, and they continued to receive the drugs for 9 to 15 days thereafter, with a mean prothrombin activity of 21% of normal. A group of 23 dogs with similar infarcts were not treated and served as controls. No significant difference was noted in the size of the infarct between the dogs receiving anticoagulants and the control dogs, and the clinical course of the dogs which survived the period of study was the same in each group. The homologous blood-clot embolus that was injected to produce the infarct was located proximal to the infarct in 38 dogs, and thrombosed arteries were found within the infarcts in 50% of all the dogs, whether or not treated with anticoagulants. No correlation as to the amount of hemorrhage was noted between the gross and the histological appearance of the infarcts. Dogs treated with anticoagulants had cerebral infarcts that were more hemorrhagic than those of the controls, and the mortality rate was higher in the treated dogs.

Perinatal Infections of the Central Nervous System. A. Wolf and D. Cowen. J. Neuropath. & Exper. Neurol. 18:191-243 (April) 1959 [New York].

The authors review the extensive literature on perinatal infections of the central nervous system, pointing out that the findings of Gregg in maternal rubella stimulated a search for other infections which might lead to similar results. A variety of congenital defects have been described in infants born to mothers who during pregnancy had mumps, measles, chickenpox, herpes zoster infection, scarlet fever, or infectious mononucleosis. A cause and effect relationship has not been firmly established in all of these, and there is not sufficient evidence that the infective agent entered and directly injured the nervous system. Prospective studies by several investigators demonstrated that the possibility of a congenital malformation occurring in the offspring of a woman suffering from an infection in the first trimester of pregnancy is not nearly as great as was at first feared.

The authors discuss spirochetal, protozoan, viral, and bacterial infections of the nervous system which occur in the perinatal period. These include congenital syphilis, toxoplasmosis, cytomegalic inclusion disease, herpes simplex infection, equine encephalomyelitis, and the bacterial meningitides and meningoencephalitides. Commenting on perinatal syphilis of the central nervous system, the authors conclude that congenital syphilis appears to be a diminishing problem as an infection of the neonatal nervous system due to the increasing efficacy of treatment of this infection. They present detailed histories of 2 patients with congenital toxoplasmosis and of 1 with cytomegalic inclusion disease, as well as 2 probable instances of herpes simplex infection. They conclude that, in spite of the great number of infective agents which may enter and damage the central nervous system in the perinatal period, infection must still be considered one of the less common causes of pathological changes in the brain at this time of life.

Delirium Tremens and Acute Liver Damage. G. Lundquist, E. Nettelbladt and H. Reichard. Nord. med. 61:433-436 (March 12) 1959 (In Swedish) [Stockholm].

Determinations of glutamic oxalacetic transaminase (GO-T) and ornithine carbamyl transferase (OC-T) in the serum were used as a test of acute liver damage in 32 cases of delirium tremens and in 10 of chronic alcoholism. Determinations of bilirubin and thymol turbidity were also made. Increased serum bilirubin was seen in only 10% of the cases of delirium tremens. Most of the patients with delirium tremens had increased serum levels of both GO-T and OC-T, presumably due to acute liver damage. Since not all these patients showed signs of acute liver damage, the latter cannot be the primary cause of delirium tremens. There was moderate to marked increase in GO-T and OC-T values in chronic alcoholics who had ingested large amounts of alcohol shortly before admission.

Studies on Spontaneous Primary Encephalitides in the Monkey: I. A Polio-Encephalitis with Predilection for the Brain Stem in the Baboon (Papio Hamadryas). L. van Bogaert. J. Neuropath. & Exper. Neurol. 18:294-305 (April) 1959 [New York].

The author observed in 3 monkeys disease similar to the human primary polioencephalitides which chiefly affect the brain stem. His first observation was made on a 2-year-old male baboon (Papio hamadryas) in 1937. In 1940 and in 1946 he was able to study 2 other baboons with disorders of this type. In the first baboon there developed simultaneously with diarrhea and fever attacks of extremely violent generalized epilepsy, with occasional Jacksonian components, bilateral hemiparesis, a postural tremor, and a left peripheral facial paralysis. In the second baboon a neurological syndrome developed suddenly, which included epilepsy, cerebellar tremor of the entire body, myoclonic jerks, transient torticollis, palsies of the 3rd, 5th, 7th, 9th, and 10th cranial nerves, and a terminal hemiplegia. The course of the illness was 17 days. The third baboon suddenly showed anger and excitement, with myoclonus, generalized tremor which was slight at rest and increased by movement, some choreoathetoid movements, paralysis of the 7th and 9th cranial nerves, and finally severe generalized hypotonia. The paroxysms of aggressiveness were followed by a period of relaxation, which was succeeded by a postictal stupor. The animal refused to eat or drink.

The pathological picture in the first 2 animals was that of a severe encephalitis of the entire brain stem, spreading anteriorly to the hypothalamus and the septal nuclei, and laterally to the claustrum. The cord presented perivascular and nodular infiltrations in the posterior more than in the anterior gray matter, with moderate involvement of the white columns. The author concludes that a meningopolioencephalitis exists in baboons which has a predilection for the brain stem. The disease has an acute and fatal course. The localization and characteristics of the disease process are reminiscent of those seen in Borna disease (encephalitis of horses, cattle, and sheep caused by a virus) and rabies. Clinically, the disease is characterized by sudden behavior disturbance (anxiety, aggressiveness, fits of temper), paretic disorders, myoclonus, postural tremor, at times transient choreoathetoid movements, cranial nerve palsies, and epileptic attacks. The fundi are normal. Modifications of the cerebrospinal fluid could not be determined. This type of meningoencephalitis has a specific clinicopathological character.

GYNECOLOGY & OBSTETRICS

Combined Treatment of Carcinoma of the Ovary. D. Buttenberg and H. Lau. Geburtsh. u. Frauenh. 19:308-325 (April) 1959 (In German) [Stuttgart, Germany].

The authors describe the method of combined treatment of carcinoma of the ovary, which has been practiced since 1954 at the gynecologic clinic of the University in Heidelberg, Germany. It consists of (1) excision of both ovaries without removal of the uterus, or, if this proves impossible, removal of the bulk of the tumor but without attempting to eradicate radically all carcinomatous tissue, since such an attempt may expose the patient to complications in the course of the surgical intervention and postoperatively; (2) repeated intra-abdominal instillation of single doses of 120 mc. of radiogold (Au^{198}), the first dose being given immediately after the operation and its administration being repeated at least once at an interval of 2 or 3 months; (3) intrauterine application of radiocobalt (Co^{60}) pearls, with a maximum load of 4,000 r placed on the bladder and the rectum; (4) percutaneous depth roentgen irradiation with use of a grid and one field, each over the abdomen and the back, with a surface dose of 6,000 r, or telecobalt therapy with doses of 4,000 to 5,000 r; and (5) continuous therapy with large doses of androgens combined with administration of prednisone.

With this treatment the survival time of 24 women with incurable carcinoma of the ovaries could be prolonged by an average of 3 months, compared with that of a similar group of 29 patients who had been treated between 1945 and 1950. In view of the highly unfavorable prognosis of carcinoma of the ovaries, this prolongation of the survival time, although it is short, is of some value, particularly since the patients had a subjective feeling of well-being. The use of cytostatic agents is rejected because of the additional risk of damage to the leukopoietic system. Hypophysectomy is advocated as a supplementary measure to hormone treatment.

Ferrodynamics During Pregnancy. R. G. Holly and W. J. Ground. Am. J. Obst. & Gynec. 77:731-742 (April) 1959 [St. Louis].

Storage iron estimates were made on 19 pregnant women, since it was found that iron depots are reduced in the majority of women at the onset of pregnancy. The demands for iron by the fetus and by the mother for extra hemoglobin synthesis are in excess of that which can be supplied by diet alone. Storage iron is "available iron" and can be mobilized for the fetal requirement or for maternal hemoglobin production. Eleven of the 12 patients studied early in pregnancy were shown to have diminished or depleted iron stores. It is significant that the patients with iron stores had hemoglobin values above 11.4 Gm. per 100 cc. These observations confirm the impression based on clinical studies that the hemoglobin level will remain normal if an iron supplement is available and provided that bone marrow function is normal. The presence of a normal hemoglobin level does not mean, though, that there is storage iron. One patient with a hemoglobin level of 11.4 Gm. per 100 cc. had no visible storage iron.

Radioiron (Fe^{59}) studies were performed on 7 patients, 3 of whom exhibited deficiency anemia caused by pregnancy. Plasma iron turnover rates were found to be decreased during pregnancy. A similar reduction in the erythrocyte iron turnover rate was observed. These findings could be explained on the basis of iron deficiency. A theory postulating a retarded erythrocyte production rate was advanced. It was based on the low erythrocyte iron turnover rate, on the retarded erythrocyte utilization of Fe^{59}, and on the relatively high liver counts obtained by surface scanning. Iron deficiency is the commonest cause of pregnancy anemia. There is apparently some degree of bone marrow suppression in association with pregnancy.

Ethical, Religious and Legal Aspects of Artificial Insemination as Viewed by a Gynecologist. L. Sbrocca. Minerva ginec. 11:158-165 (Feb. 28) 1959 (In Italian) [Turin, Italy].

Artificial insemination was condemned by the Roman Catholic church in 1897, and this position was reaffirmed by the Jesuit priest, F. Hürth, in an article published in 1946. Hürth left the discussion open for further study, because it did not involve the domain of either faith or dogma. Theologians have argued that only natural copulation, being an uninterrupted action in the process of procreation, is admissible. The author contends that the mechanism of natural coitus should not be overemphasized, because its object is procreation, but the motive force is sensual pleasure. Moreover, coitus has no bearing on the act of creating, which process is independent of the will of either the man or the woman. The author believes that moral principles cannot be offended if the result of conception, fructus ventris, is obtained either through natural coitus or by the aid of a physician through artificial insemination. Artificial insemination is thus viewed as a corrective measure for a defect of natural coitus and is justifiable only for the transmission of semen of the husband into his wife. Artificial insemination through a donor violates ethical-religious principles, and the use of such impregnation by an unmarried women is an even greater offense.

Children born by the aid of artificial insemination between husband and wife are legitimate according to the interpretation of Italian law. Recently a lower court in Italy had to decide on the first penal case of artificial insemination in that country. In the absence of an explicit provision, the court ruled that the defendant, a legally separated woman, who gave birth to a child through the semen of an anonymous donor, was not an adulteress and thus that her child was not born out of wedlock. The author concludes that artificial insemination is becoming a pressing problem, which requires passage of specific guiding rules by both lay and ecclesiastical authorities.

Fetal Mortality and Prematurity with Repeat Abdominal Delivery. A. W. Diddle, V. Gibbs and S. Lambeth. Am. J. Obst. & Gynec. 77:719-730 (April) 1959 [St. Louis].

It has been shown that fetal mortality is greater with cesarean section than with vaginal delivery. The greater loss is generally attributed to the obstetric complication leading to the hysterotomy and not to the operative procedure. Fetal salvage, even with repeat cesarean section, may, however, be less favorable than with the average delivery, since babies born in this circumstance are not infrequently premature. In this study of fetal mortality with repeat cesarean section, it was found that 11% of the babies born by repeat cesarean section or following uterine rupture were premature. This was a higher percentage than for the average vaginal delivery. More than half of the babies born by repeat abdominal delivery died either of prematurity after elective cesarean section or of anoxia in association with a rupture of the uterus. A decrease in the incidence of premature infants delivered by elective repeat cesarean section and in the number of uterine ruptures accounted for a fall in the fetal mortality in the second half of the study as compared with the first half. It appears that the danger of uterine rupture from waiting until the baby was at term was offset by the risk of elective delivery of a premature baby.

Elective repeat cesarean section is nearly as safe for the baby as vaginal delivery in some hospitals. This safety is the result of careful timing of the operation according to the maturity of the fetus. The menstrual age was found to be unreliable as a measure for determining when a pregnancy was at term. Infants delivered by elective repeat cesarean section were seldom premature if the cervix was effaced, if the crown–rump length of the fetus was at least 25 cm., as determined by palpation, and if the ossification centers were visible in the fetal epiphyses of the knees, as ascertained by roentgenographic study. Experience indicates that it is usually advisable to defer repeat cesarean section until the onset of spontaneous labor if there is doubt as to the maturity of the baby.

Normal Pregnancy and Delivery in Female Pseudohermaphroditism. F. Gans and J. Ser. Acta endocrinol. 30:424-434 (March) 1959 (In English) [Copenhagen].

The authors present what they believe to be the first report of the delivery of a healthy child of a female pseudohermaphrodite, after cortisone therapy over several years and after plastic operation. When first examined by the authors in 1953, the patient was 16 years old and complained of amenorrhea and of hair on the body and face. Her mother had suffered during pregnancy from a hypophyseal tumor and had received x-ray therapy, but the girl's development during childhood had been normal. At the time of observation the patient's voice was remarkably low. There was hirsutism on the face, extremities, abdomen, and, to a less degree, the upper part of the body. The breasts were not developed. The clitoris was about 4 cm. long. The labia majora were well developed; the labia minora were absent; and no vaginal aperture was found. Rectal examination revealed a small uterus, and both ovaries were present. The psychic attitude of the patient was feminine. Clinical and laboratory findings justified the diagnosis of female pseudohermaphroditism (congenital adrenal hyperplasia). Cortisone therapy was started in September, 1953, with daily injections of 100 mg. of the drug. About 8 months after the onset of this therapy menstruation began, and from then on it occurred in almost regular monthly cycles.

In September, 1956, the patient requested an operation for correction of her genital malformation. At this time she received injections of 100 mg. of cortisone every 4th day. Cytourethrography revealed that the orifice of the urethra was at its normal site. An x-ray picture of the pelvic outlet (after injection of a contrast medium into the sinus urogenitalis) showed a vagina, distally narrowing into a small canal; the proximal vaginal filling showed an appendage obviously corresponding to the filled cervical canal. An amputation of the enlarged clitoris was performed, and the sinus urogenitalis was incised. The vagina, lying behind, was partly freed from the underlying tissue, broadened by means of longitudinal incision, and sutured to the skin. Dilatation therapy was started after the operation and was continued at home.

Examination in July, 1957, revealed that the patient was 2 months pregnant. She was given the usual dose of cortisone and felt well during the entire pregnancy. Except for cortisone, the patient received no hormonal treatment of any kind. Despite, or maybe because of this, the breasts developed normally, the menses appeared, and hirsutism diminished. Theoretically it is conceivable that the administration of additional quantities of estrogens, as well as cortisone, might have produced adverse effects because of inhibition of follicle-stimulating hormone production by the hypophysis. The course of events in this case is in favor of the exclusive administration of cortisone. The patient received cortisone for 4½ years and during her entire pregnancy without any perceptible disadvantages. The regular control of electrolytes showed no significant deviation from the normal. The weight remained unchanged, and during the whole treatment the state of the patient's health was better than ever before.

PEDIATRICS

Studies in Sickle-Cell Anemia: XII. Further Studies on Hepatic Function in Sickle-Cell Anemia. A. D. Ferguson and R. B. Scott. A. M. A. J. Dis. Child. 97:418-425 (April) 1959 [Chicago].

Despite clinical evidence of involvement of the liver in children with sickle-cell anemia, difficulty is usually observed in quantitating hepatic dysfunction by the traditional liver function tests, such as serum bilirubin, van den Bergh, alkaline phosphatase, cephalin flocculation, total protein, and serum glutamic oxalacetic transaminase. In an attempt to obtain additional evidence of impaired liver metabolism by the use of some of the newer laboratory procedures, serum protein separation by filter-paper electrophoresis was carried out on 28 children, between the ages of 10 months and 16 years; 51 blood ammonia determinations were made on 26 children, ranging in age from 2 to 12 years; and urinary amino-acid analyses were performed on 5 children, between 4 and 10 years of age, all with sickle-cell anemia. These newer procedures proved to be similar to the traditional liver function tests in that they were not conclusively diagnostic. However, as a battery they were at times helpful in supplying additional confirmatory evidence of hepatic damage in young children with sickle-cell anemia, in whom the correlation between liver damage and the results or response obtained from the usual function tests is less reliable than in older persons.

A needle biopsy specimen of the liver was obtained from a 5-year-old boy with sickle-cell anemia, who was hospitalized during a crisis associated with a complicating pneumonia. Microscopic examination of the specimen showed that the sinusoids were dilated and plugged with sickled cells. In some areas the sinusoids were practically occluded by the stagnation of sickled and hemolyzed erythrocytes. The liver cord cells were swollen, granular, and pale, indicating early degenerative change. Biopsy of the liver is not indicated as a routine procedure in all children with sickle-cell anemia and should not be attempted by unqualified persons. Occasionally, microscopic study of hepatic tissue obtained by needle biopsy may be helpful in establishing a definite diagnosis in children in whom chemical tests are negative or equivocal in the presence of persistent spectacular enlargement of the liver, which cannot be readily explained by other causes.

Long-Term Use of Prednisone and Prednisolone in Juvenile Rheumatoid Arthritis: A Report of Fifteen Cases. E. E. Harnagel. A. M. A. J. Dis. Child. 97:426-431 (April) 1959 [Chicago].

Seven girls and 3 boys, with rheumatoid arthritis, and 4 boys and 1 girl, with rheumatoid spondylitis, were treated with prednisone and prednisolone for periods ranging from 8 to 24 months. The average age of the 15 patients was 14.4 years, and the average daily maintenance dose varied from less than 5 to 20 mg. These doses, calculated on a per pound basis, were in excess of those usually given to adults with rheumatoid arthritis. Prednisone and prednisolone were used interchangeably. Treatment with these steroids was reserved principally for those patients whose condition had not been satisfactorily controlled with acetylsalicylic acid and/or cortisone. Although 12 (80%) of the 15 patients obtained satisfactory relief from pain and stiffness, only 3 (20%) had complete remission of the disease during the period of treatment, and 6 had major or minor improvement. Six patients (40%) were unimproved or became worse, and in 4 of these progressive articular destruction was observed. A total of 28 untoward reactions, such as "moon face," acne, mild psychic changes, and striae, were observed; these were largely of minor importance and did not require a reduction of dose or withdrawal of the steroid agent. The most formidable complication was diabetes mellitus, which developed in one patient while he was receiving prednisone but which went into remission while the hormonal therapy was continued. The administration of adrenal cortical steroids to children and adolescents with rheumatoid arthritis should be limited to severe progressive cases.

Clinical Features of Infection with Hemadsorption Viruses. R. H. Parrott, A. Vargosko, A. Luckey and others. New England J. Med. 260:731-738 (April 9) 1959 [Boston].

A previous report described the recovery of 2 new myxoviruses, hemadsorption viruses, types 1 and 2, which were isolated in October, 1957, from the oropharynx of children, with acute respiratory disease. The authors report clinical data on 52 boys and 40 girls, between the ages of 2 weeks and 9 years, with respiratory tract illnesses who attended the Children's Hospital in Washington, D. C., between October, 1957, and May, 1958. Of these 92 patients, 42 had infection due to hemadsorption virus, type 1, and 50 had infection due to hemadsorption virus, type 2. Thirty-three of the group of 42 patients and 29 of the group of 50 patients required hospitalization for severe illness, such as bronchopneumonia, bronchiolitis, croup syndrome, and severe pharyngitis. The remaining 9 patients of the group with type 1 virus infection and the remaining 21 patients of the group with type 2 virus infection had minor respiratory tract illnesses and were seen during visits to the outpatient department. The more severely ill patients had respiratory distress (type 1 virus infection) or cough of croup type (type 2 virus infection). Cough, rhinorrhea, and sore throat were the major symptoms in the outpatients. Pharyngeal erythema and rhinitis were the major physical signs, but the patients who became more severely ill showed dyspnea and had abnormal lung findings, such as rhonchi and rales (associated with type 1 virus infection) or signs of laryngeal obstruction (associated with type 2 virus infection). These observations suggest that the occurrence of pneumonia or croup represents a progression from the less severe type of illness. No distinct clinical features of hemadsorption virus infections were observed to enable the clinician to make the diagnosis without the aid of a virus laboratory.

Poliomyelitis Virus Neutralizing Antibodies After Salk-Vaccination in Kindergarten and School Children: Studies on Capillary Blood with a Microdye Test. M. Just, G. Ritzel and E. Berger. Helvet. med. acta 26:65-69 (March) 1959 (In German) [Basel, Switzerland].

About 20,000 children of kindergarten and school age of Basel, Switzerland, were vaccinated against poliomyelitis in 1957. The vaccinations were carried out with Salk vaccine of American origin. The children were given 3 subcutaneous injections of 1 cc. of vaccine into the upper arm. The interval between the first 2 injections was 4 weeks and between the second and third, 6½ months. The authors describe studies carried out to ascertain whether the children had an adequate antibody level against poliomyelitis virus after the vaccination. The capillary blood was examined for virus neutralizing antibodies with the aid of a microdye test from 2 to 4 weeks after the third injection of Salk vaccine. The test used had been described by Löffler and Vogt in 1957. A macrodye test with blood obtained by venous puncture was used in some of the children as a control, and the 2 tests were found to produce identical results. Tests were made on 3 groups, of about 100 children each, a total of 281: (1) children, 4 and 5 years old; (2) children, 9 and 10 years old; and (3) children, of 13 and 14. Antibody formation was best against type 2 and poorest against type 3 poliomyelitis virus. Electrophoretic analysis of the serum proteins of children who had an insufficient increase in virus neutralizing antibodies against poliomyelitis virus after vaccination revealed no difference in comparison with the serum proteins of normal controls.

A Fatal Granulomatous Disease of Childhood: The Clinical, Pathological, and Laboratory Features of a New Syndrome. R. A. Bridges, H. Berendes and R. A. Good. A. M. A. J. Dis. Child. 97:387-408 (April) 1959 [Chicago].

The authors report on 4 boys, between the ages of 7 months and 5 years, who were referred to the department of pediatrics of the University of Minnesota Hospitals in Minneapolis with a syndrome consisting of chronic suppurative lymphadenitis, hepatosplenomegaly, pulmonary infiltrations, and an eczematoid dermatitis about the eyes, nose, and mouth. These manifestations proved to be the result of a generalized granulomatous process and were associated with a prominent hypergammaglobulinemia. All 4 patients died, and autopsy performed on 3 revealed generalized involvement of the reticuloendothelial system, including every group of lymph nodes throughout the body and, in addition, the liver, spleen, lung, and skin. The clinical syndrome presented by these children closely resembled tuberculous cervical adenitis. From the family history of one of the patients, it appeared that 2 maternal uncles had died, at the ages of 7 and 8 months, with what, by the description given by the patient's mother, may have been the same disease as that of the patient. The maternal grandfather was also supposed to have had the same syndrome. These findings suggest that the disease may occur in male members over several generations. Though periods of symptomatic improvement occurred even after the development of pulmonary lesions, these would appear to mark the terminal phase of the disease. At this time the previously suppurative adenopathy, which represented the first manifestation of the disease, became quiescent, and the debilitating systemic manifestations assumed the most prominent role, leading to death within a year of this event.

The various laboratory examinations, including determinations of gamma globulin concentration and immunological capacity, skin tests performed with antigens prepared from pathological material obtained from one of the patients, and white blood cell function tests, as well as the findings at autopsy, made it possible to differentiate this new syndrome from recognized forms of infectious and noninfectious disease producing granulomatous processes in childhood. The tests did not make it possible, though, to arrive at an etiological characterization of the syndrome, which appears to be a distinct entity, the causation of which is yet to be determined. Extensive empirical efforts at treatment have been without effect on the relentless progression that would seem to be the most characteristic feature of this syndrome.

UROLOGY

Treatment of Vesical and Prostatic Carcinoma with Atomic Medicine. C. F. Rusche and H. L. Jaffe. J. Internat. Coll. Surgeons 31:305-314 (March) 1959 [Chicago].

The authors obtained improved results in the treatment of patients with carcinoma of the bladder or of the prostate by using a combination of surgical treatment, injection of radioactive colloidal chromic phosphate, and external irradiation with a radiocobalt (Co^{60}) bomb. Although this combined treatment achieves only palliative benefit in advanced stages of the disease, some patients have achieved arrest for more than 4 years. In addition to high tumor doses being administered without untoward effects, this combination of isotopic and Co^{60} bomb therapy enables the therapist to direct the treatment accurately to the tissues involved. There is minimal damage to the surrounding normal tissue, and secondary contracture of the bladder is absent.

In carcinoma of the bladder, clinical classification, based on gross appearance and extent, is essential for deciding on the best treatment. If stage 1 bladder tumors are too extensive for segmental resection or if the trigone or outlet is involved, the authors prefer fulguration and interstitial implantation of radioactive colloidal chromic phosphate. (The isotope, which is prepared from radiophosphorus [P^{32}], has a half-life of 14.3 days.) This is followed by a full course of external rotation Co^{60} therapy if there is subsequent recurrence of the tumor.

For stage 2 tumors, segmental resection is done when there is a single infiltrating tumor which proves to be resectable. Only when subsequent microscopic examination reveals that an inadequate amount of surrounding normal mucosa has been removed, or when there is evidence of local recurrence, do the authors employ postoperative Co^{60} bomb therapy. If the tumor is nonresectable, they remove the bulk of it electrosurgically and fulgurate its base. Then they inject the isotope or radon seeds. The Co^{60} bomb is used only if there is residual disease after 3 months. When cystoscopic examination reveals multiple infiltrating tumors, the authors perform open operation and fulgurate each tumor to its base after removing the bulk of it electrosurgically. Radon seeds or the isotopes are injected at the tumor base, and Co^{60} bomb therapy is used after 3 months if the inspection biopsy is positive.

In stage 3 tumors, when operation reveals that the neoplasm is infiltrating and extending through the bladder wall into the perivesical fat or into the regional lymph nodes, the authors remove the bulk of the tumor electrosurgically and fulgurate its base. They also remove a lymph node for biopsy. In case of lymph node metastases, intensive Co^{60} bomb therapy is given, but interstitial irradiation is not used. If there is local recurrence after Co^{60} bomb treatment, a "second look" operation and interstitial isotope injection are carried out. Patients with stage 4 lesions (distant metastases) are given palliative Co^{60} therapy. Of 36 patients with carcinoma of the bladder, who were treated by this technique and followed for almost 3 years, 24 are alive, and 12 are dead. Of the surviving patients, 15 had good results, 3 fair results, and 3 poor results, while 3 have been treated recently. Of the 12 deceased patients, 1 had a good result, 2 fair results, and 6 poor results; 3 did not complete the treatment.

In carcinoma of the prostate, radical perineal prostatectomy is the treatment of choice for the patient with an operable lesion; the combined technique of isotopic-surgical therapy and Co^{60} irradiation is indicated only for the one with inoperable prostatic carcinoma. The authors previously reported their technique and results with radioactive colloidal chromic phosphate in the treatment of advanced prostatic carcinoma. Although they were impressed with the results from a palliative standpoint, there were some patients who required more than local injection treatment because of further tumor growth. Instead of giving more injections of chromic phosphate at 3-to-4-month intervals, the authors resorted to Co^{60} bomb rotation therapy, and of the 15 patients who received either the combined treatment or the Co^{60} therapy alone, at least two-thirds obtained worthwhile results.

Spontaneous Rupture of the Bladder. J. R. G. Bastable, L. R. De Jode and R. P. Warren. Brit. J. Urol. 31:78-86 (March) 1959 [Edinburgh].

The authors include under the term "spontaneous rupture of the bladder" all cases of sudden vesical rupture into the peritoneal cavity or the pelvic cellular tissue when there was no injury. This definition excludes vesical fistulas into the vagina and colon, or through suprapubic scars; rupture following instrumentation, such as cystoscopy, cystodiathermy, or litholapaxy; rupture caused by the introduction of foreign bodies or by attempts to cause abortion; extension of uterine or vaginal tears during parturition; and rupture following ulceration due to indwelling urethral catheters. Four patients with spontaneous rupture of the bladder were seen at the London Hospital during the last few months, and a search through the hospital records since 1900 revealed 2 further cases. The histories of these 6 patients are described, together with a review of 66 cases collected from the literature in the last 25 years.

These 72 cases included 66 of intraperitoneal rupture, 5 of extraperitoneal rupture, and 1 of combined intraperitoneal and extraperitoneal rupture. All 5 patients with extraperitoneal rupture were men. Two of these patients had stricture, one an enlarged prostate, and one a vesical papilloma with obstruction of the internal meatus; 3 of them recovered, and one died under the anesthetic. The 5th case of extraperitoneal rupture was due to tuberculosis, and the patient died. Of the 66 cases of intraperitoneal rupture, 14 occurred in women and the remainder in men. The youngest patient was 21 years old. All 3 patients with recurrent rupture were men. With regard to causation, the intraperitoneal ruptures fall into 2 main groups, depending on whether the rupture was due to a lesion of the bladder wall or was caused by overdistention of the bladder. There were 28 patients with lesions of the bladder; these included 9 with tuberculosis, 5 with carcinoma, 7 with cystitis, 6 with scars, and 1 with "lipomatosis." The 38 patients in whom retention was the cause of rupture included 4 with neurological disorders, such as tabes dorsalis or paraplegia, 19 with various forms of urinary obstruction, and 15 in whom the rupture was considered to be secondary to a reflex retention. Rupture usually occurred through the vault of the bladder and was small in lesions of the bladder wall.

Diagnosis in spontaneous rupture depends on a history of pain and disturbance of micturition and the signs of peritonitis. Catheterization and withdrawal of blood-stained urine confirm the diagnosis, but occasionally the urine is clear. The mortality in the series presented was 47% and has not fallen during the last 25 years. Carcinoma, tuberculosis, and enlarged prostate accounted for two-thirds of the deaths.

Family with Cystic Kidneys and Cystic Liver in Several Generations. A. L. Ørbeck. Tidsskr. norske laegefor. 79:193-195 (Feb. 15) 1959 (In Norwegian) [Oslo].

Twenty-four cases of cystic kidney in one family, both sexes equally represented, are reported. In 4 cases there was simultaneous cystic liver. The symptomatology was fairly uniform with acute and more or less marked hematuria, at the onset or later in the course, and proteinuria, possibly with infection of the urinary tract and pyuria, hypertension and uremia, together with symptoms as the result of growth of the tumor. The clinical course of the disease seems to be fairly uniform and gradually leads to death from uremia, if expansion of the renal tumor or intercurrent diseases do not advance the course. Transmission is apparently abiotrophic dominant. The disease may be latent for many years or manifest itself late in a tissue which was hitherto normal.

INDUSTRIAL MEDICINE

Chelating Agents in the Therapy of Beryllium Poisoning. R. Cash, R. I. Shapiro, S. H. Levy and S. M. Hopkins. New England J. Med. 260:683-686 (April 2) 1959 [Boston].

The authors studied the effect of edathamil (ethylenediaminetetraacetic acid [EDTA]) on the renal excretion of beryllium in 2 patients with proved beryllium pneumoconiosis. The causative agent was found by spectrographic analysis of pulmonary parenchyma obtained by lung biopsy. Both patients had been exposed to beryllium for varying periods during their employment. Both had moderate to marked pulmonary insufficiency. Trisodium edathamil was slowly infused intravenously in concentrations of 0.5 to 1.0 Gm. dissolved in 1,000 cc. of 5% dextrose in water. The drug was administered intermittently over a 3-day period. The first patient received a total dose of 2.8 Gm., and the second patient a total dose of 3 Gm. during this period. On the 4th day of therapy the second patient received a total dose of 3 Gm. of calcium edathamil. Twenty-four-hour or 48-hour samples of urine were collected and analyzed for beryllium content with the aid of a mass spectrograph.

The results showed that edathamil therapy induced a definite increase in the renal excretion of beryllium. This increase was observed in the total daily excretion as well as in the concentration per liter of urine. Calcium edathamil was found to have a similar effect as trisodium edathamil. Edathamil, a polyamino carboxylic acid, forms a water-soluble, relatively un-ionizing chelate with polyvalent cations and has been shown to cause marked increase in the excretion of heavy metals, without the usual toxicity associated with reaction of the metal ion with body tissues. It is suggested that long-term intermittent therapy with a chelating agent such as edathamil may so deplete the body stores of baryllium ion that the clinical course or progress of the disease may be favorably affected.

Talc Pneumoconiosis. A. O. Seeler, J. S. Gryboski and H. E. MacMahon. A. M. A. Arch. Indust. Health 19:392-402 (April) 1959 [Chicago].

The authors report clinical and postmortem observations on 2 men, aged 73 and 70 years, with talc pneumoconiosis who worked for about 25 years as "lay-up" men in a factory manufacturing rubber-coated cable. Their work was to stand near the machines that coated the cables with rubber and coil the freshly coated cable into pans that were filled with talc. It was the practice to shovel a layer of talc into each pan and then coil the wire on this layer. As soon as a coil of wire was laid in the pan, talc was shoveled on in preparation for the next layer of cable. Although dust counts were not available for the period of years that the men worked with talc, the work created a great deal of talc dust, and there was no ventilation, so dust counts would have been very high. The autopsy findings in both patients were similar and showed the pattern of a chronic, crippling, progressive disease of the lungs by scar tissue, injury, and destruction of blood vessels, dilatation of bronchi and alveoli, and slighter degrees of fibrosis and atelectasis throughout the rest of the lung. The presence of large quantities of doubly refractile needle-shaped particles in the area of fibrosis would appear to be the causative factor responsible for this particular form of pneumoconiosis. Although the lungs of both patients showed extensive fibrosis, this did not show a specific pattern that might be of diagnostic value. In neither case were the classic laminated nodules observed.

THERAPEUTICS

Placebos in the Evaluation of Treatment in Rheumatic Diseases. E. F. Traut and E. W. Passarelli. Illinois M. J. 115:181-183 (April) 1959 [Chicago].

Four hundred twenty-six patients with various rheumatic diseases, such as rheumatoid arthritis, degenerative arthritis, psoriatic arthritis, and shoulder syndromes, were given placebo tablets for 4 weeks or less. Those patients who did not respond, or ceased to respond, to placebos in tablet form were given hypodermic injections of 1 cc. of an isotonic solution of sodium chloride at weekly visits for 4 weeks or less. Of the 426 patients, 226 were relieved for significant periods by placebo tablets. Of the remaining 200 patients, 114 were relieved by injections of saline solution. Thus, 340 of the 426 patients responded favorably to placebo therapy.

Fluctuation of the clinical manifestations of the chronic forms of these rheumatic diseases is axiomatic. Their principal symptom is pain, a function of the cerebrum, which is influenced by many factors. In all chronic illnesses, including rheumatic disorders, the psyche plays an important role, affecting favorably or unfavorably the course of the disease, even deciding its outcome or its inception. Thus, the use of placebo medications seems justified. The number of rheumatic patients found to benefit from such medications is about the same as the number favorably influenced by any or all the methods of therapy reported in other studies. This was evident in sufficient degree and in a large enough group of patients to justify the continuance of placebo therapy. The number of patients benefited did not seem to be essentially altered by resorting to salicylates or even to cortisone.

Current Status of Amphotericin B in the Treatment of the Systemic Fungus Infections. V. D. Newcomer, T. H. Sternberg, E. T. Wright and R. M. Reisner. J. Chron. Dis. 9:353-374 (April) 1959 [St. Louis].

Promising laboratory studies with Amphotericin B, a new polyene antifungal antibiotic, prompted the authors to report on 22 patients with various systemic mycoses, who were treated with that drug either under direct observation or in cooperation with other physicians. The ages of the patients ranged from 2½ to 62 years. They were followed up after treatment for periods varying from 5 months to 2 years. Fourteen of the 22 patients had coccidioidomycosis; 5, cryptococcosis; 1, North American blastomycosis; 1, candidiasis; and 1, mycetoma. Five of the 14 patients with coccidioidomycosis had coccidioidal meningitis. Three of these 5 patients improved clinically, but the titer of their complement-fixation tests for coccidioidomycosis showed no essential change. Two of these patients remained clinically improved over 4-month and 5-month follow-up periods, while the third patient had a relapse 7 months after treatment. One patient was lost to follow-up, and the 5th patient died after 7 weeks of treatment. Six of the remaining 9 patients with disseminated coccidioidomycosis showed clinical evidence of improvement while under direct observation. This included an early increased feeling of well-being, improved appetite, gradual weight gain, increased strength, decreased fever, stabilization, reduction in size, or complete resolution of pulmonary infiltrates, healing of draining sinuses, and partial or complete healing of cutaneous lesions. Of the 5 patients with cryptococcic meningitis, 3 showed moderate to marked clinical improvement. The spinal fluid cultures remained negative, pleocytosis returned toward normal, and the spinal fluid sugar and hydrodynamics reverted toward normal; however, some abnormalities still existed in the spinal fluid. Two patients with cryptococcic meningitis died; one had received Amphotericin B orally in doses of 16 Gm. a day for a total period of 16 days. The drug had a beneficial effect on the patient with North American blastomycosis and on the patient with candidiasis, but the condition of the patient with mycetoma did not improve.

Results revealed that Amphotericin B is poorly absorbed from the gastrointestinal tract and that, when given orally, the drug failed in the majority of cases to influence appreciably the clinical course of any of the systemic mycoses, even when it was administered in large doses over long periods of time. However, intensive oral therapy with Amphotericin B should be given a fair trial in patients for whom intravenous therapy is not possible. The drug has been well tolerated in oral doses ranging from 8 to 12 Gm. a day, and one patient tolerated doses as high as 16 Gm. a day. The intravenous route has appeared to be the more satisfactory method of administering Amphotericin B. In the adult the optimal dosage is in the range of 0.7 to 1.4 mg. per kilogram daily over a period ranging from 2 weeks to 4 months. Evidence has indicated, though, that the drug is better tolerated and is equally effective in the same dosage level when administered on alternate days. The initial dose should be in the range of 5 to 10 mg. a day, with increments of 5 to 10 mg. depending upon the reaction of the patient. A persistent drop in the hematocrit has been observed in some patients. It is, therefore, recommended that appropriate hematological, liver-function, and renal-function studies be performed on all patients who receive prolonged treatment with Amphotericin B.

A New Antituberculous Medicament: Alpha-Ethyl-Thioisonicotinamide or 1314 Th: Experimental Bases of Its Clinical Utilization. N. Rist, Miss F. Grumbach and D. Libermann. Presse méd. 67:625-626 (March 28) 1959 (In French) [Paris].

Alpha-ethyl-thioisonicotinamide, also known as ethioniamide or 1314 Th, is as active against tubercle bacilli resistant to isoniazid as it is against normal tubercle bacilli. Its experimental activity lies between those of isoniazid and streptomycin; consequently, it can be used to replace these drugs in all cases in which the bacilli have become resistant to either or both. The appearance of isoniazid resistance can be avoided by the administration of ethioniamide and isoniazid in association. The fact that both these drugs can be given orally will make this combination easier to administer than those of isoniazid and PAS or isoniazid and streptomycin.

Laboratory studies show that resistance to ethioniamide alone develops as rapidly as resistance to isoniazid. Clinicians who wish to use ethioniamide to obtain not merely transient improvement in functional symptoms but rather definitive sterilization of the sputum should keep this danger constantly in mind and should prescribe it only in association with one, or better still two, other antituberculous drugs that are still active against the patient's bacilli. The choice of the drug or drugs to be used in such an association presupposes a thorough study of the sensitivity of the bacilli to all antituberculous drugs. Such drugs are usually given in combinations, and in vitro studies may provide an agreeable surprise by showing that the bacilli are still sensitive to one of the drugs that has already been given in a combination to which resistance has apparently developed.

The general rule that the best antituberculous drugs are poor antileprous drugs, and vice versa, does not seem to apply to ethioniamide. Early trials of isonicotinic thioamide without the ethyl group in the alpha position (3264 Th) apparently produced encouraging results, and it is reasonable to suppose that ethioniamide, which is 4 times as effective as the unmodified substance against Mycobacterium tuberculosis, will also be more effective against the bacilli responsible for leprosy (Hansen's disease).

Chlorothiazide. C. Laroche and A. Nenna. Presse méd. 67:549-551 (March 21) 1959 (In French) [Paris].

Chlorothiazide is a sulfonamide and a carbonic anhydrase inhibitor, with diuretic properties quite like those of the mercurial diuretics, except that it has no toxic effect on the renal cells. A second advantage possessed by chlorothiazide over other substances that act directly on the renal tubules is that it does not provoke acidosis or massive calcium excretion, and this makes it more manageable than acetazolamide. It comes in 0.5 Gm. tablets, to be taken by mouth, and the usual dose is from 1 to 2 Gm. daily, given in from 2 to 4 divided doses. Intravenous administration is also possible, but the results are apparently no better than when the oral route is used.

Cardiac edema provides the principal indication for chlorothiazide. The diuretic effect usually appears 2 or 3 hours after the drug is taken. The action of digitalin seems to be favored by chlorothiazide, but clinical and electrocardiographic signs of digitalis intoxication may appear rapidly. These complications can be explained by a drop in the potassium level in the blood. Digitalis should, therefore, be used in moderate doses; its effect should be closely watched; and the patient should be given from 1 to 4 Gm. of potassium chloride a day by mouth. Special care must also be taken in prescribing chlorothiazide for cardiac patients presenting signs of renal insufficiency with azotemia. Slight albuminuria and moderate hyperazotemia are not contraindications to the use of chlorothiazide; indeed, the renal signs may even improve under chlorothiazide treatment if they are related to the cardiac insufficiency, but the azotemia must be watched because it may rise rapidly. Other patients in whom chlorothiazide must be used with caution are those with cirrhosis: the results are usually mediocre, and the complications may be severe.

Chlorothiazide is effective in certain nephrotic syndromes without hyperazotemia and in edema of pregnancy, but in patients with renal insufficiency it is dangerous and does little to increase diuresis. Patients with hypertension are sometimes helped by treatment with chlorothiazide. Its hypotensive effect is very inconstant when it is used alone, but when it is associated with other hypotensors it potentiates their action, especially in patients who have undergone sympathectomy. The mechanism by which this hypotensive effect is produced is uncertain, but the predominant, if not the exclusive, part in it seems to be played by increased sodium excretion.

Vitamin B_{12} Absorption in Pernicious Anemia: Investigations of Defect in Vitamin B_{12} Absorption Induced After Long-Continued Treatment with Some More Recent Combination Preparations. M. Schwartz, P. Lous and E. Meulengracht. Ugesk. laeger 121:353-363 (March 5) 1959 (In Danish) [Copenhagen].

The blockade in vitamin B_{12} absorption due to peroral treatment with preparations of type B_{12} plus swine pylorus mucosa has been confirmed in a large amount of material. The blockade phenomenon is frequent and often occurs after a few months' treatment. Vitamin B_{12} bound to swine pylorus mucosa is poorly resorbed, even if homologous intrinsic factor is present. Changes in the intestinal flora apparently cannot explain the blockade. It is a new phenomenon dependent on the new type of oral preparations.

Triamcinolone Myopathy. R. S. Williams. Lancet 1:698-701 (April 4) 1959 [London].

The synthetic hormone, triamcinolone, appears to be slightly more potent than prednisolone, and does not cause sodium retention. There is also evidence that triamcinolone is less likely than its precursors to induce peptic ulceration. Several side-effects have been noted, which have not been seen with other steroids. Headache, drowsiness, postprandial flushing, anorexia, and progressive loss of weight have been reported, but the most serious has been muscle weakness. The author presents 3 patients in whom muscle weakness was observed after triamcinolone therapy. Muscle biopsy was performed on 2 of them and showed widespread muscle damage. Electromyographic evidence of a primary muscle-fiber lesion was observed in all 3 patients.

In 2 of the patients weakness first appeared within 3 weeks of commencing triamcinolone therapy, and muscle power improved rapidly when prednisolone in equivalent dosage was given. In the third patient the weakness could be attributed to an exacerbation of the underlying disease, but its time of onset, the similarity of the clinical picture, and the absence of other evidence of deterioration strongly suggested that it was caused by triamcinolone. Though muscles of the shoulder girdle were affected, the weakness was greatest in those of the trunk and pelvic girdle. This proximal muscle syndrome closely resembles that seen in the muscular dystrophies and in those myopathies (presumed to be of metabolic origin) which may complicate thyrotoxicosis and carcinoma. The myopathic origin of the weakness was supported in cases 1 and 2 by the preservation of the tendon reflexes and the absence of sensory loss. In case 3 the picture was complicated by neurological signs of long standing.

In metabolic studies it was demonstrated that the nitrogen balance was similar on triamcinolone and on prednisolone therapy. The effect of the 2 steroids on calcium excretion also appeared to be much the same, and the serum electrolytes (including serum magnesium) were within normal range throughout. The author directs attention to the similarity between this myopathy and that induced in rabbits with massive doses of cortisone. He suggests that the different molecular structure of triamcinolone may potentiate this particular effect, and myopathy may thus occur with much smaller doses.

Reversible Amytrophy Complicating Treatment with Fludrocortisone. K. MacLean and P. H. Schurr. Lancet 1:701-703 (April 4) 1959 [London].

The authors present the history of a 49-year-old woman in whom severe hypotension developed after surgical removal of a craniopharyngioma. Fludrocortisone, thyroid extract, vasopressin, and other preparations were required to counteract the hypotension, diabetes mellitus, and other postoperative conditions. After treatment with fludrocortisone had been continued for about a year, the patient noticed progressive muscular paralysis, especially unsteadiness in her legs. The muscular paralysis improved dramatically on withdrawal of the fludrocortisone, and progressive recovery followed. It is suggested that, in view of the cases of muscular weakness reported with triamcinolone (9-alpha-fluoro-16-hydroxyprednisolone), the presence of a fluorine atom in the 9-alpha position in the steroid nucleus may be responsible for this complication.

Hydrochlorothiazide, A New Saluretic. J. Zatuchni, W. King and M. Resinski. Am. J. M. Sc. 237:479-487 (April) 1959 [Philadelphia].

Hydrochlorothiazide, the 3,4-dihydro derivative of chlorothiazide (the 3,4-double bond in the heterocyclic ring of chlorothiazide being saturated by 2 hydrogen atoms), was administered orally to 15 patients. In the experimental animal this compound produces a marked increase in the excretion of sodium and chloride, with relatively little increase in the excretion of potassium. The patients to whom the drug was given were all, but one, males and ranged in age from 37 to 78 years. Ten patients had coronary artery disease; 5, benign essential hypertension; one, cirrhosis and nutritional heart disease; one, phlebitis and metastatic prostatic carcinoma; one, arteriosclerosis of the aorta; and one, aortic stenosis. Eleven patients showed cardiac enlargement of variable degree. Cardiac failure, obvious or latent, was present in 6.

Dietary sodium was limited to 200 mg. daily, and a liberal fluid intake was encouraged for the patients in this series. The dose of hydrochlorothiazide was almost always 50 mg. 4 times daily; in one patient, however, it was 100 mg. and in another 25 mg. 4 times daily. The drug was given over a period of 2 to 24 days for a total of 145 patient-day observations. After treatment, 12 of the 15 patients showed a decrease in body weight, varying from one-half to 14 lb. (0.23 to 6.4 kg.) and averaging 4½ lb. (2 kg.). The remaining 3 patients showed an increase, varying from one-half to 1½ lb. (0.23 to 0.7 kg.) and averaging 0.8 lb. (0.4 kg.). The greatest loss of weight occurred among those with edema. Except for occasional weakness no symptoms were observed in patients who lost weight. Rather, there was frequently a sensation of euphoria, because breathing was much improved. Control blood pressure persistently exceeded 90 mm. Hg diastolic in 3 patients; 2 of them, who had lost 3 and 14 lb. (1.3 and 6.4 kg.) of body weight, respectively, became normotensive, and one showed no change after the treatment.

Serum concentration of sodium and chloride dropped markedly in 2 patients; in one of them a fall in serum concentration of potassium was also observed. Both these patients returned to normal when the drug was withdrawn and a regular diet was instituted. No changes were observed on electrocardiographic examination, with the exception of one patient in whom prominent U waves developed. This change, however, could have been due to underlying myocardial disease, for the serum concentrations of electrolytes were normal and there was no weight loss. The authors believe that hydrochlorothiazide, like chlorothiazide, is an antihypertensive but not a hypotensive agent and that it may produce hyponatremia, hypochloremia, hypokalemia, and hyperuricemia. The maximal dose of hydrochlorothiazide appears to be 200 mg. daily.

The Association of a Synthetic Anabolic Compound, 4-Chloro-Testosterone Acetate, with Prednisone in the Treatment of Hepatic Cirrhosis of the Morgagni-Laennec Type with Ascites. A. Bisaro, M. Casasola, C. Milesi and R. E. Genero. Minerva med. 50:449-459 (Feb. 14) 1959 (In Italian) [Turin, Italy].
